A Tipple of the Monongahela River Consolidated Coal & Coke Co., and Fleet of Coal Barges on Monongahela River at Pittsburgh, Penn.

18 Fifty-Ton Railroad Cars Loaded In a Day With One Baldwin-Westinghouse BARSTEEL Electric Mine Locomotive

understood the business ground up.

MOTORMAN ESTABLISHES RECORD AT SCALP LEVEL

SPECIAL TO JOHNSTOWN DEMOCRAT.

SCALP LEVEL, Sept. 19—What is believed to be the highest record ever made in any section was made today in No. 1 mine of the Scalp Level Coal Mining company, one of the John Lochrie operations, when 18 steel cars were loaded by one motorman. The motorman who made the record output was Victor Gustasson. The foreman at No. 1 is William B. Wilson.

Eighteen steel cars of coal loaded in a single day with but one motorman is the highest run that has ever been made in this vicinity and it is believed that it has never been equalled anywhere.

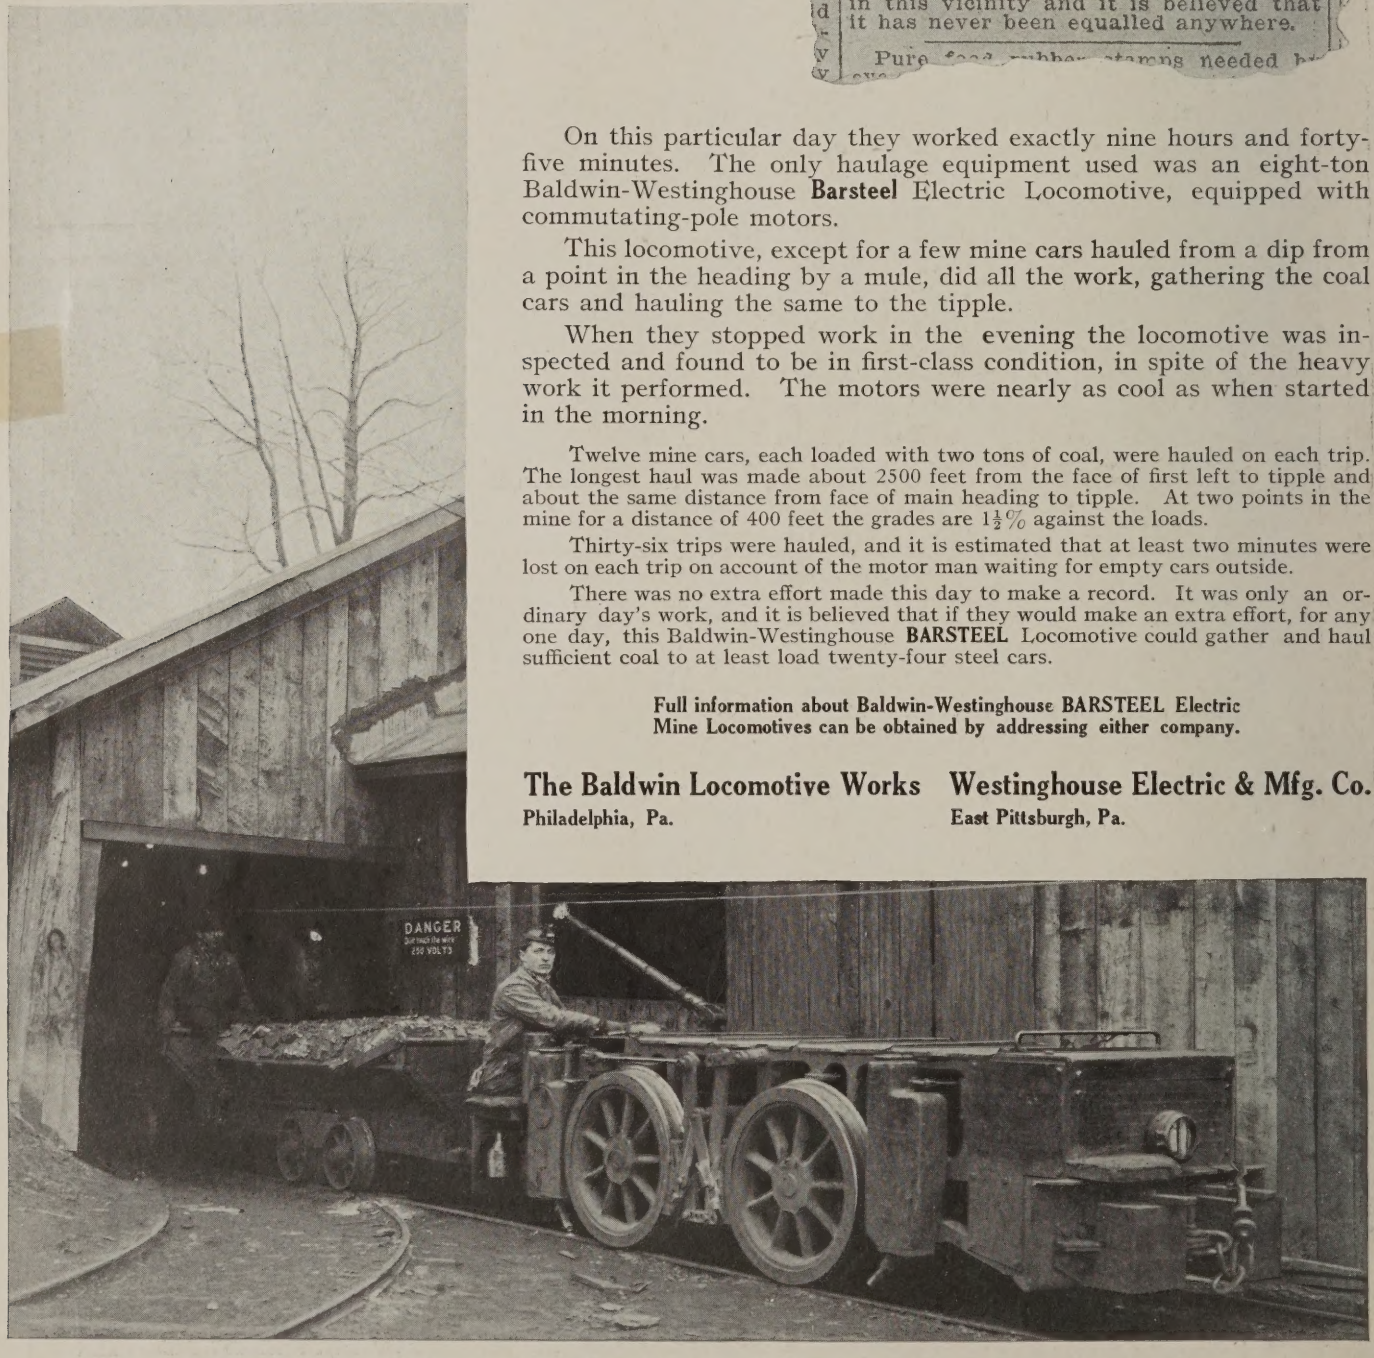
Pure [illegible] stamps needed by

On this particular day they worked exactly nine hours and forty-five minutes. The only haulage equipment used was an eight-ton Baldwin-Westinghouse **Barsteel** Electric Locomotive, equipped with commutating-pole motors.

This locomotive, except for a few mine cars hauled from a dip from a point in the heading by a mule, did all the work, gathering the coal cars and hauling the same to the tipple.

When they stopped work in the evening the locomotive was inspected and found to be in first-class condition, in spite of the heavy work it performed. The motors were nearly as cool as when started in the morning.

Twelve mine cars, each loaded with two tons of coal, were hauled on each trip. The longest haul was made about 2500 feet from the face of first left to tipple and about the same distance from face of main heading to tipple. At two points in the mine for a distance of 400 feet the grades are 1½% against the loads.



Thirty-six trips were hauled, and it is estimated that at least two minutes were lost on each trip on account of the motor man waiting for empty cars outside.

There was no extra effort made this day to make a record. It was only an ordinary day's work, and it is believed that if they would make an extra effort, for any one day, this Baldwin-Westinghouse **BARSTEEL** Locomotive could gather and haul sufficient coal to at least load twenty-four steel cars.

Full information about Baldwin-Westinghouse BARSTEEL Electric Mine Locomotives can be obtained by addressing either company.

CONTENTS

WITH PRINCIPAL ARTICLES SUMMARIZED

*Illustrated Article

FOREWORD: *Page* 1

Allowance must be made for the fact that "man is a social being," and if we wish to suppress the saloon and consequent payday celebrations, we must substitute some means that will permit the miner to satisfy his craving for companionship. COAL AGE, Vol. 5.

IDEAS AND SUGGESTIONS: *Pages* 2-3

Striking at the Root of Trouble—One Reason Why Workmen are Dissatisfied.

*SOME NOTES ON INTERIOR WATER MOVEMENT: *Pages* 4-5

Nearly 10 million tons of coal a year are shipped down the Ohio River. Due to low-water stages, navigation is only open a portion of the time. The Government contemplates an expenditure of 100 million dollars in order to make water shipping possible the year through. COAL AGE, Vol. 5.

WAGES AND PRICES IN THE PITTSBURGH DISTRICT: *Pages* 5-6

The coal-mining industry in the Pittsburgh district has raised wages between 62 and 92 per cent. since 1897, and the cost to the purchaser has only increased 54 per cent. The cost of operation of the Pennsylvania R.R. absorbs only about 79 per cent. of the total receipts, but in coal mining, the operating expenses involve almost all the gross income. Jesse K. Johnston. COAL AGE, Vol. 5.

*WORKING A STEEP COAL SEAM: *Pages* 7-9

Details of methods employed in mining coal from several seams which lie on a dip of 60 degrees. Notes on drawing pillars and timbering. As much as 90 per cent. of the coal is recovered. Simon H. Ash. COAL AGE, Vol. 5.

COAL-MINING HISTORY OF MUHLENBERG COUNTY, KY.: *Pages* 10-11

The west Kentucky coal field was one of the earliest developed in the United States. For years the coal was won without powder. Reminiscences of early mining history. Otto A. Rothert. COAL AGE, Vol. 5.

THE DAWSON MINE EXPLOSION: *Pages* 11-12

*EFFICIENCY OF PORTABLE ELECTRIC MINE LAMPS: *Pages* 12-14

Formulates a specification for portable electric mine lamps. These lamps must give at all times no less light than a Wolf lamp in perfect order with a 1-in. flame. The bulbs must last for 300 hr. and the batteries a full working year of 12-hr. days. H. H. Clark. COAL AGE, Vol. 5.

COAL AND COKE NEWS: *Pages* 32-35

COAL TRADE REVIEWS: *Pages* 36-40

SECRETARY F. K. LANE ON PUBLIC COAL LANDS: *Pages* 15-16

The report of Franklin K. Lane, Secretary of the Interior, to the President on the public coal lands and immediately allied subjects. He declares that Alaskan affairs should be administered by a board of appointed officials, that coal lands should be leased, not sold, in both the West and in Alaska, and that the present system of selling is inoperative and based on mere guess work. COAL AGE, Vol. 5.

*A WATER SPRAY FOR DRILLS: *Pages* 16-17

COAL FREIGHT RATES FROM THE HOCKING DISTRICT: *Page* 17

*EMERGENCY UNHITCHING DEVICE: *Page* 17

WHO'S WHO—IN COAL MINING: *Pages* 18-19

A sketch of the life and work of John P. Reese. COAL AGE, Vol. 5.

*CONCUSSION AS A CAUSE OF EXPLOSIONS: *Pages* 19-21

A big blower of gas will not raise a dust cloud, but projected into such a cloud 150 ft. long, it will propagate with low pressures and will probably, under favoring conditions develop a most violent explosion. COAL AGE, Vol. 5.

Does Advertising Pay—*the Reader?*

The Weekly Ad-Talk Page

That is not the angle from which it is customary to view this "grandold" question.

In the orthodox concept of advertising it is the *advertiser* who is pictured as eternally mulling over the question—"Does advertising pay?"

But how about the *reader*?

Does it pay? Is it worth your while to make a practice, each week, of thumbing through the selling section of COAL AGE? Or is it time wasted?

You have got your own answer—and if you are reading this, we have pretty good proof as to the nature of your answer.

Perhaps the answer of the Ad Manager—who doubtless sees much more advertising and knows many more COAL AGE advertisers than you, although he lacks your buyers' viewpoint—will be of interest to you. At any rate, here goes:

First, advertising *does* pay the reader—and pays him big. Just imagine this world *without* advertising; to focus down to our immediate question, imagine a world of coal mining newspapers sans advertising section. You wouldn't begin to be the *well educated buyer* that you are now.

You'd know one, or perhaps two products, in this line and that. You'd not know them *all* as you do now. *You'd not know enough to make a really wise buy.*

But—secondly—I'm compelled to admit that it doesn't pay the reader as well as it should pay or as it will next year and the year after.

Every good ad is the product of a man with a "nose for news"—as they say in newspaperdom. And the man with a "nose for news" is simply a man with the faculty of picking out and presenting, in an attractive manner, facts and ideas that interest the reader.

In many ads there is not the news interest that there should be or could be. Ads are still all too frequently blatant reiterations of alleged superiority, loud proclaimings of statements that are not proved and that cannot even hope to interest the reader. But ads of this type are growing fewer and fewer in number.

Advertisements in your technical papers are today very much more attractive in appearance than ever before. They are more informative and better written. Hence they are interesting and worth reading.

And what has already been accomplished in this direction is just the beginning. Each year sees the percentage of dead ads decreasing and the number of live, interesting ads on the increase.

What do *you* think? Does advertising pay the reader? Take a half hour some evening and put your ideas on paper. Send them along to the Ad Manager. I'll wager that they will make a very interesting ad-talk page.

COAL AGE

Vol. 5 NEW YORK, JANUARY 3, 1914 No. 1

"Treat men as pawns and nine-pins and you shall suffer as well as they. If you leave out their heart, you shall lose your own." We doubt if we should have had the courage to print this quotation from Emerson, at any other season, but at the beginning of a new year, we, in common with all mankind, are bubbling over with courage.

Emerson was of the opinion that the normal man is a social being; we doubt if any sensible person would disagree with him on this point, however, there are many normal men who lose sight of this fact when they are called upon to deal with others.

Saloons, labor unions, national holidays, pay-day celebrations, all give testimony to "man the social being." Attempts to arbitrarily suppress them altogether give evidence of some one's stupidity.

The miner at work in his room, loading coal, is almost an isolated creature. Compare his surroundings with those of the clerk, the brick layer, the machinist, or most any other laborer. Do you wonder then that he craves companionship when his day's work is completed?

We know of a camp that does not boast of a saloon nor a labor organization, but every afternoon, during the summer months, the men congregate in front of the commissary and play marbles—don't laugh, we are in earnest; name furnished on request. A happier lot of men we have never observed. If all men were possessed of such simple tastes, mining camps as residences could be put in the same class as the Y. M. C. A. Annex.

Between the two extremes—the saloon and the marble club—there are many possibilities, all of them time tested and approved; for example, first-aid teams, prize gardens, reading rooms and night schools, school advancement committees, moving picture shows, old-fashioned picnics, etc., etc.

Oh, yes, remarks the pessimist, you left out "blind tigers." The blind tiger proprietor is at best an outlaw, he never trusts his customers and they seldom trust him. At pay day, while the men are flush, his glasses may ring, but the daily gatherings characteristic of the saloon are wanting.

"Man is a social being." We have never met a person who questioned the truth of that statement. We have met hundreds of men, however, who have never given the matter a moment's consideration, and they are the ones who invariably howl, "down with the saloon," the moment such an establishment interferes with their employees' working capacity; likewise, when the lodge or a labor organization seems to interfere with the output of their mine, they are "agin" them To all such we would point out, as a New Year's suggestion, the possibilities for social activity that lie somewhere (in every camp) between the saloon and the marble club.

If you have reached the stage where you are in doubt as to which substitute for the saloon would be most effective in your camp, you may consider yourself out of danger; it's only the fellow who hasn't realized that there is a substitute, who needs attention.

Some Notes on Interior Water Movement of Coal

SYNOPSIS—Nearly 10 million tons of coal a year is shipped down the Ohio River. Due to low-water stages, navigation is only open a portion of the time. Government contemplates an expenditure of 100 million dollars in order to make water shipping possible the year through.

To those who live along the Ohio and Mississippi Rivers, the passing of a boat down (south) with a coal tow is of little interest. When these boats plod their way up-stream (north) still less interest is manifested by those who are not directly interested. But, to the coal operator, the shipper and the receiver, such items mean much. That a coal tow has passed a certain point on its Southern journey is the best news the shipper can receive, excepting, only, the brief wire from the captain that the fleet has been landed safely at Louisville, Memphis or New Orleans.

Boats Working in Ohio River Pool No. 1 to Get Tows Ready to Start South

It is only at certain seasons of the year now that coal is sent from the upper Ohio and Monongahela pools to the Southern markets. The cause of this is simply that a navigable stage of water does not remain in the Ohio River from Merrill, Penn., south, throughout the twelve months. It is just possible that river shipping of coal on the upper Ohio prevails only from seven to nine months during year. This, of course, is because the system of locks the Federal Government is building in the Ohio River is not complete.

From Pittsburgh, the distance down the Ohio to Cairo, Ill., where the Mississippi is touched, is approximately one thousand miles. The Ohio River drains a quarter of the greatest states in the Union, and this importance of the river is one of the reasons that Congress has been so liberal in appropriating millions of dollars annually for the river and harbor improvements. The projects now under way, or the completion of the series of locks and dams will cost upward of $100,000,000. The greatest burden of freight now carried on the Ohio is coal, all coming from Pennsylvania, Ohio, West Virginia and Kentucky.

Importance of the Project

To have a navigable stage of water in the Ohio River during twelve months of the year would mean that the coal shipping tonnage would be more than doubled. Each lock or dam costs upward of $2,000,000 and there will be fifty or more of these between Pittsburgh and Cairo. This will permit a 9-ft. stage of water throughout the entire year, and, it is said, the constant stirring up of the water by coal and passenger boats will prevent the formation of the customary "ice bridge."

Effects of the Opening of the Panama Canal

Time is now drawing near when shipping will be permitted through the Panama Canal. This means that New Orleans will be made a great reloading point for coal consigned to receivers along the Pacific Coast. In turn, it also means that more coal will be shipped out of the western Pennsylvania, eastern Ohio and Kanawha fields for Southern reloading. If the Panama Canal was now open for traffic, it would be impossible to ship coal from the Pittsburgh harbors to New Orleans throughout the year unless the system of locks and dams was completed. Shipping could and would be done at certain seasons of the year, when navigable water would permit, but the completion of the river-improvement program would insure shipping during every week in the year.

Specifications have only recently been presented to Congress asking for an appropriation of about $10,000,000 for work in the Ohio River during the coming fiscal year. All such appropriations are generally agreed to with little if any argument, for the fact is realized that the completion of the 50 or more locks and dams will make the Ohio Valley and its tributary country a beehive of industry, insofar as river coal shipping is concerned.

Basing future shipments of coal by river to Southern points on the records for the fiscal year ending June 30, 1910, when 8,366,786 tons were floated down stream, this volume will be increased 50 per cent. or more when the improvement program is finally completed.

Wages and Prices in the Pittsburgh District

By Jesse K. Johnston*

SYNOPSIS—The coal-mining industry in the Pittsburgh district has raised wages between 62 and 92 per cent. since 1897, and the cost to the purchaser has only increased 54 per cent. The cost of operation of the Pennsylvania R.R. absorbs only about 79 per cent. of the total receipts, but in coal mining, operating expenses involve almost all the gross income.

In view of the fact that the present wage scale for mining bituminous coal in the competitive states expires Apr. 1, 1914, I thought it might be interesting to make a study of the wages and selling prices of coal in the Pittsburgh district for the last 16 years, and to set forth some facts which are misunderstood by the public.

If the coal business could have some assurance during the next two years that actual conditions would be as favorable as today, then there would be no necessity for writing this paper. But in the absence of such assurance if we can know just whither we are drifting in this period of readjustment, reconstruction and legislation, we can better determine what to do, and how to do it.

As one has said very truthfully, "As a whole the coal business is the most indispensable, the most unprofitable, the most maligned, and misunderstood of all the mediums through which the welfare of the people is secured. It is the most important, and most helpless, having in it the power to command, and yet having a nonresistant mass, accepting only with a feeble protest the criticisms of a misinformed public." The public thinks it can cheapen this essential product by destroying that machinery by which it is now being produced at a lower price than anywhere in the world.

Why is it that the great coal industry in the thickly populated industrial districts of Pittsburgh, an industry producing sixty-six million tons of coal in the year 1912 in Allegheny, Washington and Westmoreland counties, is not on a more solid business foundation? On analysis, the answer is, that the cost of production leaves a very small margin of profit for such a large investment, for we must remember that the labor charge is only 75 per cent. of the whole cost of production, there being in addition "overhead costs" and the cost of selling in competitive markets.

One of the statements you hear frequently is that the wages have not advanced in proportion to the selling price of coal, so it is well to nail that statement at once with actual facts.

The Wage Scales in 1897 and 1912 Compared

Referring to the chart and going back to the year 1897, the mining rate in the Pittsburgh district is found to have been 55c. for pick mining lump coal in the thin-vein district; $1.78½ was the maximum rate for day labor and 5c. a ton was a fair cost for materials and supplies. These were deplorable times in the mining industry, and just three years previous to this time. Coxey's Army made its memorable march through southwestern Pennsylvania on its way to Washington.

COMPARISON OF WAGES AND SELLING PRICES

	Wages per Ton		Wages per Day			Average Selling Price		
Year	Lump Coal	Run-of-Mine	Max.	Min.	Supplies	Allegheny	Washington	Westmoreland
1897	$0.55	$0.3558	$1.78½	$1.52½	$0.05	$0.67	$0.55	$0.85
1898	0.66	0.4272	1.90	1.75		0.71	0.58	0.71
1899	0.66	0.4272	1.90	1.75		0.74	0.74	0.88
1900	0.80	0.5171	2.28	2.10		1.01	0.97	1.04
1901	0.80	0.5171	2.28	2.10		1.00	0.87	1.01
1902	0.80	0.5171	2.28	2.10		1.04	1.03	1.04
1903	0.90	0.5817	2.56	2.36		1.22	1.15	1.18†
1904	0.85	0.5494	2.42	2.23		1.02	0.94	0.95
1905	0.85	0.5494	2.42	2.23		0.96	0.91	0.96
1906	0.90	0.5817	2.56	2.36		1.03	1.02	0.97
1907	0.90	0.5817	2.56	2.36		1.10	1.07	0.99
1908	0.90	0.5817	2.56	2.36		1.05	1.03	0.97
1909	0.90	0.5817	2.56	2.36		1.00	1.00	0.87
1910	0.95	0.6140	2.80	2.49		1.08	1.06	0.98
1911	0.95	0.6140	2.80	2.49		1.06	1.05	0.97
1912	1.00	0.6464	2.95	2.62	0.10	1.09	1.08	1.01
Per cent. advance	81.89	81.69	65.25	71.80	100		53.62	

† Year of anthracite strike.

It was in this year that the 55c. rate was made by the action of the late Patrick Dolan, president District No. 5, United Mine Workers of America, who reduced the wage rate so that the union mines could compete with those of the New York & Cleveland Gas Coal Co. This led to a strike on July 4, 1897, culminating in the interstate convention later, Sept. 13, 1897. The eight-hour day was adopted in Chicago, January, 1898.

Now looking at the record of the year 1912, the last of which we have any data, the rate is found to be in the Pittsburgh thin-vein district $1 per ton for pick mining lump coal. The maximum rate for day labor is $2.95, and 10c. per ton is the cost for material and supplies.

These figures mean an advance of 81.89 per cent. for pick mining. Machine mining has also advanced so that the wage rate for cutting has risen 65.85 per cent., and that for loading after machines 92.29 per cent. The maximum wage for day labor has risen 65.25 per cent., the minimum day-labor wage has increased 71.80 per cent., while supplies now cost twice as much as in 1897. In that year the selling price in Allegheny, Washington and Westmoreland counties averaged 69c. for run-of-mine

*General mining superintendent, Pittsburgh Plate Glass Co., Creighton, Penn.

Note—An article entitled, "A Study of Wages and Selling Prices of Coal in the Pittsburgh District," read before the Coal Mining Institute of America at its winter session in Pittsburgh.

coal, while in the year 1912 this price amounted to $1.06. Thus the average increase was 53.62 per cent.

The Coal Man's Dollar

Loosely speaking, let us call the $1.06 received in 1912 the coal man's dollar, and see how far it goes. A misdirected public opinion is demanding high wages, high taxes, good preparation, safety, compensation, conservation and yet there are not enough of cents in the coal man's dollar to meet all these demands, and allow a fair profit for the investment.

Let us make some comparisons. The cost of operating the Pennsylvania R.R. in 1912, was 78.69c. for every dollar received, and in 1912 that corporation paid only 37.1 per cent. higher wages than in 1900.

On the other hand, the wage rate of mining in the Pittsburgh district increased 51.51 per cent. in that period of time and during parts of 1910 and 1911 a group of mines in the Pittsburgh region, part in the thin-vein district and part in the thick vein, some well situated, some with less favorable conditions, expended for mining, labor, fuel, general office expenses, taxes, depreciation and royalty 99.09c. per ton. Note that this expenditure did not cover interest on bonds.

The average selling price received was $1.09 per ton, leaving a difference of 10c. per ton to take care of dividends and bonded interest, so you see there is not enough left for safety, conservation, compensation and a fair return on the investment.

Is this true of the coal industry? Let me quote you Edward W. Parker, United States Geological Survey, from his excellent paper read before the American Mining Congress, Philadelphia, Penn.:

"Pennsylvania by long odds the most important producer of bituminous coal with an output of 137,300,000 tons in 1909, showed a total expense of $117,440,000, and a value of product of $129,550,000, leaving a balance on the profit side of little over $12,000,000, or about 3⅓ per cent. on the capital invested, which was $358,600,000."

The Consumer Pays for Freight and Thinks He Is Paying for Coal

If you told the consumers of domestic coal that the operators of the Pittsburgh district only received an average of $1.06 per ton for their coal at the mines, or about 4c. a bushel, he would place you in the Ananias Club immediately, for in the mind of the average consumer there is a firm conviction that the coal operators are a lot of robber barons who fix the price of coal at their pleasure.

Now let us analyze the situation, by taking an example during the year 1912. The consumer purchased a car of run-of-mine coal in the Pittsburgh district at $1.10 per ton at the mine. The freight bill would cost him 35c. per ton and the cost of hauling and unloading would cost him $1 or a total of $2.45 per ton. The retail dealer quoted him 10c. per bushel delivered in his cellar or $2.60 per ton. On examination he finds he has paid 15c. per ton for the retailer's profit and also that this profit and the transportation are large items in his coal bill.

The representatives of labor say to the operators of the Pittsburgh district, "If you have not enough business sagacity to get a better price for your coal, it is no fault of ours." The steel manufacturer sells his steel at profit; the butcher demands fair payment for his meat; the shoe merchant gets a good price for his shoes; and the clothier secures a profit for his clothes. Why does not the coal operator get a good price for his coal? What is the remedy?

The Only Efficient Price Raiser

The operators might make a secret agreement to raise the price of coal, but they cannot do this without fear of the law. The railroads have been trying for 5 years to raise freight rates and they have failed because public opinion and the Interstate Commerce Commission have been against them. Who, then, does raise the price of coal? The United Mine Workers of America, who by their compact organization, have been able to secure a large advance in wages during the last 16 years. The question is whether the operators cannot profit by taking some lessons in organization from that aggressive body and by giving the actual conditions of the coal industry more publicity.

We may well question whether the cost of labor in the production of coal has not reached an apex, beyond which we should not allow it to pass until the consumer understands that in the end he must pay for the value of the coal in the ground, and wages of the miner, the cost of safety appliances, compensation, conservation, new laws of taxation and a reasonable profit to the operators.

There is a tremendous waste of investment in coal-mining property, due partly to the antagonistic attitude of the public and partly to the unorganized condition of the industry, and it seems that the business of mining can only be improved by better organization, some efficiency engineering on the selling force, and more general knowledge of the actual conditions under which the coal industry is operating. This publicity might well help to secure some changes in the federal laws.

An American Invention Is Introduced into Great Britain

N. K. Bowman, general manager of the American Mine Door Co., Canton, Ohio, has just returned to this country from a visit through England and Scotland, where he installed a number of automatic ventilating doors for coal mines. Mr. Bowman took occasion to visit a number of his Majesty's inspectors in England and Scotland and found these men especially pleased with the general design of the mine door manufactured by his company. It was found that the "American" mine door fully meets the requirements of the recent British mine law, which provides among other things that trap doors must be so constructed that they will not blow open when the air is reversed. The object of this law is to make it possible to reverse the air in a mine where an accident has happened. It frequently occurs that fire is an element of coal-mine catastrophes, and in such a case, every possible precaution must be taken to carry the poisonous gases away from the main exit, so that the men may have a safe means of escape.

Lignites may be profitably used in (1) Gas producers. (2) Specially constructed boilers. (3) Briquettes. The U. S. Reclamation Service has a boiler at Williston, N. D., that burns lignite untreated, shortly after it is taken from the mine. When lignite is to be used for briquetting it should be thoroughly crushed, then dried until it contains not more than from 5 to 10 per cent. of moisture, then compressed while still warm.

Working a Steep Coal Seam

By Simon H. Ash*

SYNOPSIS—Details of methods employed in mining coal from several seams which lie on a dip of 60 deg. Notes on drawing pillars and timbering. As much as 90 per cent. of the coal is recovered.

The following method of working steep seams is practiced with slight modifications in the different beds of the Pierce County coal measures. At the mines of the American Coal Co., Spiketon, Wash., the beds dip from 60 to 65 deg. Four seams are being worked, Nos. 6, 8, 9 and 10, and the prospects are good for substantially increasing the output in the course of the next year. At present about 500 tons are being produced each day.

Fig. 1. Yards and Trestle at No. 8 Mine. Also Shows Power House and Washery

The product of the mines is a sub-bituminous coal, which is prepared in three sizes, lump, nut and steam. This coal finds a ready market for domestic and steam purposes in and about the Puget Sound cities. The No. 10 bed, also called the "Lady Wellington," is the best seam now being worked. A slope has been driven across the dip on a grade of 32 deg. to the second level. No. 8 bed was opened in a similar manner, while No. 6 bed has been reached by a rock tunnel driven westerly 670 ft. from the second level in No. 8 seam.

These three beds are of the Burnett series and are on the east slope of the Wilkeson anticline dipping from North 76¾ deg. East to North 67½ deg. East. The average strike is North 15 deg. West. The Eastern measures in this section have never heretofore had an authentic correlation and reliable data for these seams is still lacking. The coal beds in this section are a subdivision of the Eocene period and the coal measures as shown in the columnar section have been determined by survey and tunnel driving for an interval of 2000 ft. Detailed sections of the different coal beds are shown on the columnar section sheet.

The present company has had charge of the property since February, 1912, and much credit is due General Manager D. R. Swem, and Superintendent John Hutchinson, for their consistent efforts to modernize and render safe the company's collieries.

Method of Mining

The coal of the No. 10 bed is 3½ to 4½ ft. thick between walls, a detailed section of which is shown in Fig 5. The coal is mined by the chute-and-pillar system, for the character of the walls is such that mining by wide breasts is impracticable. The coal does not fire spontaneously. With the exception of a few small jumps, the bed has been regular for the entire length of all gangways so far driven. A diabase dike was passed through by a short rock tunnel in the south end of the field, however, beyond this dike, the coal was found in place and regular.

The gangway, which is the intake airway, and the counter gangway, which is the main return airway, are driven parallel. The counter gangway is up the pitch from the gangway and the stumps are from 20 to 25 ft. thick. Chutes are driven 6 ft. wide from the gangway to the counter on 50-ft. centers, from which point they are driven 8 ft. wide up the pitch to the boundary.

The entire mine is driven by contract, same being between the company and the United Mine Workers of

*Mining engineer, American Coal Co., Spiketon, Wash.

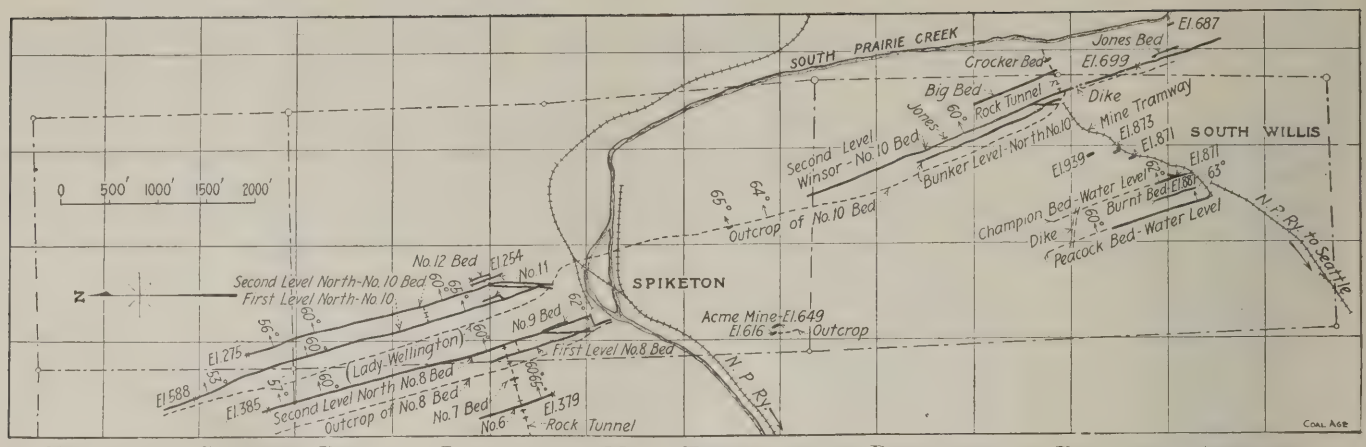

Fig. 2. Map Showing Relative Location of Main Entries with Reference to Principal Surface Features

America. The distance apart of the crosscuts on the pitch is agreed in the contract to be such that the blocks will not exceed 50 ft. in length, and will be 6 ft. wide. Between every other chute, what is termed a half-chute is driven 6 ft. wide from the gangway to the counter. Where much gas is encountered or conditions warrant such action, half-chutes are driven between all the chutes. Each half-chute is a traveling way between the gangway and the counter, and from it access at all times can be made to two chutes. Hirsch electric lamps are used by the miners in all gangways.

A Brattice Is Carried Up to Face

As shown in Fig. 3, a board brattice is carried from the counter in the center of the chute to the face. The inby compartment is used for the manway. The boards are nailed on the coal side to a line of props up the center

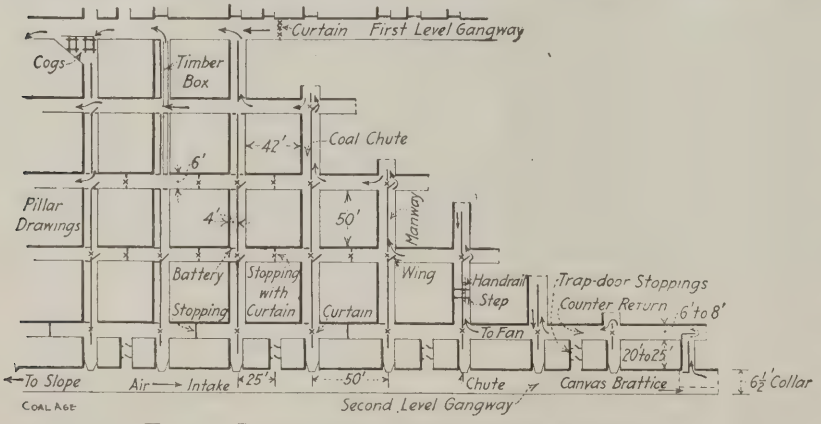

Fig. 3. Details of Ventilating System

the canvas curtain and extending to the wing post set in the center and slightly back in the crosscut. This wing not only deflects the air into the crosscut, but prevents any coal from passing below the crosscut as same runs into the coal side through the canvas curtain. There is also no danger to men who may happen to be coming up the chute.

Batteries are built at every other crosscut and, if necessary, at every crosscut, and the chutes are worked full. This not only arrests the coal and reduces breakage, but aids the ventilation and makes it safe to pass from one chute to another through the crosscuts. A chute starter runs coal from the batteries when necessary.

All shooting is done on the solid. Holes are drilled with the ordinary hand machines and the blasting is done with 20 per cent. Dupont stumping dynamite, a shot lighter firing the holes. Only one miner works in each

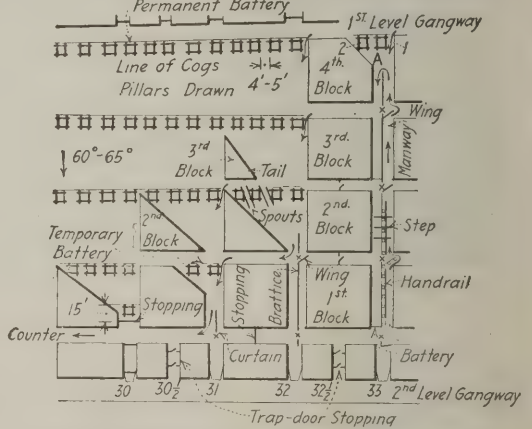

Fig. 4. Method of Pillar Drawing

of the chute. These props are set from 2 to 4 ft. apart, depending upon the character of the walls. Hand rails are fastened to the props on the manway side and steps on the bottom are made by placing a prop above the brattice props and placing one end of same in a notch in the rib.

The chute between the low side of the gangway and the counter is always kept full, thus preventing any leakages of air from this source. At every crosscut and on the counter, canvas curtains 2x2 ft. are hung in the brattice; access across the chutes can be made through these openings at all times. At each crosscut, wings are built of boards from the bottom to the roof on the manway side of the chute, the same starting at the chute brattice below chute. The average rate of advance in the chutes is 8 ft. per shift.

Because of the heavy pitch, nothing can be gobbed and everything between walls must be taken out and separated at the cleaning plant. Timber is brought down from the surface to the top gangway, to which the chutes from the second level are driven. One of these chutes is used as a timber-way from which props are taken to all parts on the pitch.

Drawing the Pillars

In Fig. 4 is shown the method of pillar drawing. Four chutes are usually driven to the boundary in advance of the pillars, three of which are usually working at one

time. The pillars are drawn on the outby side of the chute as follows: Referring to Fig. 4, No. 30 pillar is finished. When a pillar is to be drawn, the crosscuts of the chute are well timbered and a cog as 1 in 33 pillar is built on the low side of the top lift or crosscut as the case may be.

This cog is placed as closely as possible to the inside rib of the chute. The corner of the block as *A* in the fourth block is then worked off, and as soon as room permits, a second cog as 2 is placed 4 to 5 ft. from the first as shown in drawing. A temporary battery of props is built above this latter cog, to aid traveling across the face and prevent anything from coming down from above and injuring the men below or knocking out the props.

Attacking the block in this manner is called taking off the angles. This is continued until the half of the block is worked off as shown in block 2 of pillar 31, leaving what is called the tail. The same course is pursued on the next block below, as shown in block 1 of pillar 31, after which the tail or half of the block above is worked and run out. When a tail is to be run out as shown in block 3 of pillar 32, part of which has been run out, the temporary battery above the cogs is replaced by the spouts or wooden chutes as the tail is worked off. The coal is then run out between the cogs through the spouts, after which a permanent battery is placed above the cogs.

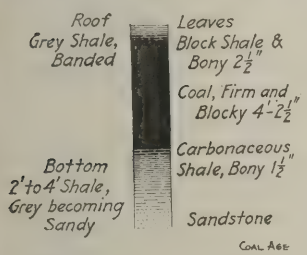

FIG. 5. A DETAILED SECTION OF SEAM

The cogs and the batteries are built of 6-ft. props. In this way the pillars are drawn to the first block from which only an angle is taken off as shown in pillar 30, and a cog and permanent stopping are placed in the chute neck. The arrows show the direction of the air current. Under favorable conditions 2250 sq.ft. of this ground has been taken out in 10 shifts of eight hours each, and as much as 90 per cent. of the coal has been recovered. The roof stands well and the breaks occur above the cog lines and are held up by the cogs. As the coal is being drawn, none of the timbers are knocked out by the shots. Other props are set as the angle face advances.

NOTES ON TIMBERING

The timbers are all cut at the mines, but the lagging used is 1-in. sawed lumber in the chutes and split lagging in the gangway, heavy ground, and in the chute batteries or bulkheads. The gangway sets are made of heavy pole trees, set 6 ft. apart and consist of two legs and a collar above which split lagging or props must be placed to safeguard against the coal roof.

Props are set 3 ft. or more apart, depending on the walls, above which cap pieces are placed if the roof is bad, otherwise they are set in a hitch. They are slightly underset, and if the bottom is bad, sills are used; if not, they are set in a hitch in the bottom.

As the cars are loaded from the chutes on the gangway and the coal spills more or less over both sides of the car, it was considered more economical to depart from the usual custom and place the ditch on the hanging-wall side of the gangway.

Mules are used for hauling the cars on the gangway as the hauls are still short, but these will be replaced soon by mine locomotives. Trips of three or four cars are hauled up the slope. These weigh loaded about one ton.

The agreement with the United Mine Workers of America specifies that all miners not on a contract rate shall receive $3.80 per day. In No. 10 mine, the men receive $3.25 per yd. for chutes, $2.50 per yd. for cross cuts, $5.25 per 90 sq.ft. of pillar removed, $1.25 per cog and $14 per yd. for gangway work. They buy their own powder, fuse, caps, tools, etc. Powder is sold to them at the mines at the rate of $3 per box of 25 lb. of 20 per cent.

FIG. 6. KICKBACK AT NO. 8 MINE

dynamite, fuse at 60c. per 100 ft., and 5X caps at $1 per 100.

Improvements in the way of preparing and handling the coal are under way, all of which when completed will make a safer and more profitable mine.

An Early Gasoline Engine

BY NEWELL G. ALFORD*

One of the first gasoline locomotives was that furnished by W. F. Prouty to the St. Bernard Mining Co.'s No. 9 mine in the year 1898. It was built either at Newark, N. J., or Philadelphia, Penn., and was installed by Mr. Prouty himself who made a trip to Earlington for that purpose.

It had a 20-hp. engine, which was set upright in the truck and had only a single cylinder and single-chain drive from the engine to the axle. The transmission was very delicate and the motor stalled on reversing. Moreover, the locomotive lacked weight and gave off quantities of smoke, which was, of course, very objectionable. Finally a magneto was put on the engine and when this failed to give the desired result, the locomotive was consigned to the scrap heap. It was used in the mine for about one year, but was never able to pull a full trip of loaded cars.

Erratum

In our issue of Dec. 6, p. 846, the statement was made that the boilers in the Hauto power plant are of the Maxim type. This should have read of the Stirling type.

*Earlington, Ky.

Coal Mining History of Muhlenberg County, Ky.

By Otto A. Rothert*

SYNOPSIS—The west Kentucky coal field was one of the earliest developed in the United States. For years the coal was won without powder. Reminiscences of early mining history.

Coal is Kentucky's greatest natural resource, and the mining of it is rapidly becoming a greater factor in the commercial history of the state. About 30,000 men are now employed in the various coal mines. At present, however, there are three times that number employed by the various manufacturing establishments in the state and nine times 30,000 are connected with farms as operators, managers and tenants. Twenty years ago the number of miners was comparatively insignificant.

Social Conditions in Muhlenberg County

To show the bearing of coal mining on local history I have selected Muhlenberg County in the West Kentucky field as an example. There are now 26 commercial coal mines in Muhlenberg with payrolls amounting to about $2,000,000 a year. This is almost double the amount of the county's agricultural products; tobacco, the leading crop, seldom exceeds $300,000. The county has a population of about 30,000 of which 3500 men are employed in and around the mines. About 95 per cent. of the miners were born in America, of whom one fourth are native Muhlenbergers. About 5 per cent. are foreigners and 25 per cent. are negroes.

Ground for home sites near mines is cheap in Muhlenberg, and, as a result, about 15 per cent. of the miners own the houses in which they live. The percentage of home owners is increasing. This is especially true in and near Central City which is now the largest town in the county and maintains good schools and churches. That the mine owners are interested in the welfare of their people is shown by the fact that at Graham and Luzerne they offer cash prices to their miners for the best kept home premises, whether these belong to the company or not.

Kentucky Was in the Market before 1830

Tradition has it that about one hundred years ago Alney McLean, who later became a member of Congress, accidentally discovered that the "black rock" found on his farm near Green River would burn. However, wood being plentiful and more convenient, his discovery was regarded as a matter of little consequence. About 1820, his son, William D. McLean, opened up what was known as the McLean drift bank. It is said he was one of the first men to report the existence of coal in western Kentucky.

As early as 1830 a few barges of coal were mined at the McLean drift bank and sent down Green River to Evansville. About that time coal was taken from the Mud River mine and hauled to Russellville in ox wagons, a distance of 30 miles. It usually required three days to make the trip over what is still called the "Old Coal Road." This coal was used by the early blacksmiths who called it "rock coal," thus distinguishing it from charcoal, which, for many years, was the only coal burned in their forges.

The great extent and probable value of the deposits of coal in Muhlenberg was given very little thought by local people before 1854 when David Dale Owen, America's greatest geologist, published the First Report of the Geological Survey of Kentucky. In this book he calls attention to the existence of thick beds of coal in about 25 different places in the county and points out, in a general way, the territory underlaid with coal. The many observations made since his day have added very little to his discoveries, but have merely verified his statements regarding the extent of the field.

Later Developments

By 1875, or a few years after the railroad, which is now the Illinois Central, was built, no less than a dozen mines were in operation in the county along that line, and when, in 1882, the Owensboro branch of the Louisville & Nashville R.R. was completed, more were opened along its tracks. As years rolled on other and larger mines were opened and now the output has placed Muhlenberg at the head of the coal-producing counties in Kentucky. In the meantime, coal lands have advanced from $4 and $5 per acre to $50 and $100.

In 1900, when commercial mines were still comparatively small, producing about 400,000 tons a year, the population of Muhlenberg was 20,000. In 1910 the output reached almost 3,000,000 tons and the population was 29,000, an increase of 45 per cent. over the population of ten years before. Most of this increase was due to mining. During this same period, the increase of population for the United States was 21 per cent. and for Kentucky about 7 per cent.

Hoskinson's Reminiscences

William H. Hoskinson, who all his life long has lived near Mud River mine, speaking of the methods employed there some forty years ago, says:

"Those who are familiar with none but the present methods of mining coal cannot easily realize on how diminutive a scale the old Mud River mine, or any other old coal mine, was formerly worked. In 1871-72, when my father, Jackson Hoskinson, operated this mine under a contract with Hall & Ryan, he put out more coal than had ever before been produced at this place in the same length of time. But there are mines in Muhlenberg county now that produce more coal in one week than did old Mud River during the entire two years of my father's contract.

"Modern methods, as we know them today, were never in use at Mud River. Much coal has been produced here by the light of candles and the old 'Dutch lamps,' but these were displaced long ago by the more convenient de-

---

Note—Article entitled "Coal Mining and Its Bearing on Local History," read before the Kentucky Mining Institute, Dec. 9, 1913.

vices from which have evolved the present oil and carbide lamps. The drill, needle, and scraper were never seen here until about 1869. Before that time all coal was wedged down.

Slack Separated by Rake and Wasted

A good steel sledge and 5 or 6 steel wedges were among the essentials of a collier's kit; he also had a heavy iron rake, with which he separated his coal, being careful to load nothing that would pass through the teeth. His car was supposed to hold 10 bushels. When it was filled a homemade wooden ticket was attached to it and a 'pusher' pushed it out of the room into the 'lie-way,' where it was coupled to one or two other cars and pulled by a mule to the tipple. Only one mule was used in the mine, and he never went any farther than the 'lie-way.' In fact, small as he was, it was necessary in many places to remove some of the roof or bottom to make it possible for him to reach the 'lie-way.' The track throughout the mine was of wood. For a long time car wheels without flanges were used, the flange, or guard rail, being part of the wooden track. In the course of time these smooth-faced old wheels and the wooden track were superseded by flanged wheels and iron rails.

Early Squib Making

"Blasting powder, it is said, was first used here about 1869. This was the beginning of a new epoch at Mud River, for the churn-drill, needle and scraper soon began to take the place of the sledge and wedges. All the coal was mined 'on the clear' and 4 or 5 in. of powder was considered a good shot.

The little squib now so common was then unknown. In its stead the miners used a joint of wheat-straw filled with gunpowder, which was set off by means of an oiled paper placed under the straw and attached to the coal by a small lump of clay. When I was a boy I made many of these squibs, leaving the joint in one end of the straw and stopping the other end with soap to keep the powder from running out."

Muhlenberg County has an area of about four hundred square miles, all of which is underlaid with coal. However, only about two-thirds of this area, or 270 square miles, is, it is said, underlaid with the coal beds Nos. 9 and 11, which are the thickest seams and practically the only ones now being worked. Each foot of thickness of a bed of this coal is estimated to produce 1000 tons to the acre, and since No. 9 and No. 11 have a combined average thickness of from 10 to 11 ft., these two beds will run, according to this estimate, about 10,000 tons to the acre, or 6,400,000 tons to the square mile, and 1,728,000,000 tons to the 270 square miles. Thus, assuming that the coal is uniform and estimating the output at three million tons per year, these two beds alone could be worked, according to these figures, for about six centuries, or until about the year 2500 A. D.

From experience gained with dust explosions in gaseous mines it appears that undercast air crossings are the best in the more gaseous operations. The distance between the floor of an undercast and the roof of the road it crosses, should be at least 10 ft., though the character and strength of the rock may at times increase or modify this estimate. It is not necessary, as a rule, to line the road above with masonry, though the undercast itself must be carefully lined. The road above acts as a relieving arch to the undercast and takes care of most of the weight of the over-lying strata.

The Dawson Mine Explosion

We called attention some time ago to the fact that electric shot firing has its disadvantages because it creates a sense of security which is not justified in practice. There is always the possibility that a shot may be fired accidentally by a stray current or intentionally by some man who violates the rules. The evidence obtained at the Dawson mine shows the latter has been the cause of at least one disastrous explosion.

Mine No. 2 which was the scene of the disaster was ventilated by an exhausting Jeffrey fan having a capacity of 200,000 cu.ft. of air per min. for a 2-in. water gage or twice that for a 5-in. gage. It was not, the general manager assures us, a gaseous mine though occasionally some gas was found. It was worked with open lights. The chemist took samples of mine air in remote parts of the workings and gobs, and made determinations of their chemical constituents and of the quantity of dust in suspension. The fire bosses made daily tests for gas with the Wolf safety lamp and were under the immediate supervision of the mine inspector.

Electric Shot Firing of Undercut Coal with Permissible Explosives

The coal was all undercut and was shot by permissible explosives only, Monobel Nos. 2 and 5 being employed. About two-thirds of the undercutting was done by hand and one-third by Sullivan and Goodman machines. Electricity was used for haulage, for operating mining machines and lighting main entries.

At 3 p.m., the shot inspectors were accustomed to enter the mine and distribute detonating caps to the men and later they connected the shooting wires. Each entry was provided with a separate switch which was enclosed in a box. This switch was kept locked open until all the men were checked out of the mine. The shot inspectors closed all division switches on their way out as they proceeded to the surface. Finally when it was certain that all the men were out of the mine, the main switch at the entrance was closed. This completed the entire circuit and all the shots were thus fired instantaneously.

The shot inspectors then proceeded into the mine with Wolf safety lamps and noted if there was any fire, missed holes, broken timber or caves. The findings were reported to the mine foreman and any needed action was taken. Water pipes and a complete system for humidifying the mine air were in use.

About 270 men are usually employed in the mine, but 284 were underground when the explosion occurred on Oct. 22, at 2:55 p.m. The men employed were mostly Italians. The explosion killed most of the 261 victims by its direct violence. Few were killed by falls of rock and only 10 to 14 by afterdamp.

The Rescue Work.

The helmets were brought to the mine immediately after the explosion and the rescuers started into the working and had already explored the seventh west entry of the Highline and proceeded to the air shaft before the fan had commenced running. The explosion doors were blown off and the air course leading to the fan was damaged, so that it took one hour and thirty minutes to make the necessary repairs. The fan started at 4:25

p.m. The rescue car of the Bureau of Mines arrived 18 hours after the explosion. The coal companies of New Mexico and Colorado rendered valuable service for which the Stag Cañon Fuel Co. desires to express its thanks and appreciation.

Two helmet men were killed but the exact circumstances under which they were overcome is not known. A small fire was discovered immediately after the explosion which was easily extinguished with water. Another was found later and was put out by fire extinguishers and water. The only places where men were found alive was in the 13th and 14th east entries of the High-line.

The verdict of the coroner's inquest placed the blame on an unidentified miner. Seldom has the cause of an explosion been so certainly determined. The miners were not allowed to fire shots, and it will be noted from the report of R. H. Beddow, state mine inspector that this rule was violated by the man whose carelessness caused the disaster. The remarks follow:

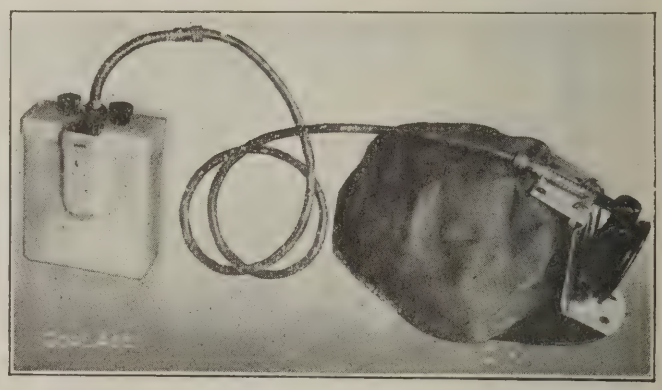
The explosion was caused by an overcharged shot, which was fired in room No. 27 off the ninth west entry in mine No. 2. This shot blew the coal into the gob for a distance of 40 ft., creating much compression and stirring up and igniting the coal dust. The explosion spread from this point all over the mine. The shot-firing wires were traced from the shot back to the first crosscut between rooms Nos. 26 and 27. It then turned into room 26 and was traced to within 50 ft. of the ninth west entry, where it was attached to a cut-in.

The wire then led out of room No. 26 into the ninth west entry and was traced along that heading to room No. 24 where it was connected to the switch convenient to the trolley wire. This switch was also cut in. A piece of copper wire was found wrapped around the trolley wire opposite this switch and a piece of shooting wire, the right length to connect the switch with the trolley wire, was found on the top of a loaded car which stood between the switch and the wire which was wrapped around the trolley wire. An electric detonator was also found on the floor near this switch. It was thus clear that the shot had been fired from the trolley wire.

Efficiency of Portable Electric Mine Lamps

By H. H. Clark*

SYNOPSIS—Formulates a specification for portable electric mine lamps. These lamps must give at all times no less light than a Wolf lamp in perfect order with a one-inch flame. The bulbs must last for 300 hr. and the batteries a full working year of 12-hr. days. The costs of purchase and maintenance and the weight are not considered.



The first requisite of a lamp is the production of light, and for mining service it should burn steadily and with undimmed brilliancy for a certain number of hours of every day in the year. The next requisite is lightness, that is, a lamp should not weigh so much that it hampers a man's movements or becomes a burden to him. The next requirement is that the cost of operation and maintenance shall be consistent with the work done and the benefits received. Another requisite which does not require discussion is that the electrolyte shall not spill or leak while the lamps are in use.

Weight, Cost and Capacity

If we assume that this last mentioned requirement does not need further consideration, we can group the qualifications of portable electric lamps under three main heads as follows: Weight, cost and capacity.

The weight of a lamp can be easily ascertained and each prospective user of a lamp must decide for himself whether or not its weight is excessive. Under the head of cost would be included the first cost of the equipment, as well as all proper charges for operating and maintaining the lamp. Some of these charges will vary with each installation and whether or not the cost is excessive will depend somewhat upon the conditions which surround each case.

The capacity of the lamp is taken to mean its ability to produce a certain amount of light for a definite number of hours per day, every day in the year if need be. A lamp that can do this with the fewest interruptions has the greatest capacity for performing the duty for which it is intended. The capacity of a lamp as thus defined takes into consideration not only the ampere-hour

The Wico Cap Lamp

capacity of the battery and the efficiency of the lamp bulb, but also the life of battery plates, the mechanical strength of parts and the resistance to wear and tear.

We need to define (1) what is the proper amount of light for a lamp to give; (2) the proper time it should burn each day, and (3) what are reasonable interruptions of service and how often they may occur.

The Proper Amount of Light in Lumens

To measure truly the illuminating power of a portable

*Engineer-in-charge of electrical investigations, Bureau of Mines, Pittsburgh, Penn.

Note—Final part of paper read Dec. 5, 1913, at the winter meeting of the Coal Mining Institute of America.

electric lamp, we must consider not only the intensity of light (or candlepower), but also the solid angle over which the intensity is maintained. A lamp which gives an intensity of light of one candlepower all around gives twice as much light as one which gives a light of equal intensity half way round it. The term "flux" is used by illuminating engineers to designate the product of intensity and the angle over which it is exhibited, since this product most truly represents the light which flows from the lamp. The unit of flux is called a lumen and is about $^{8}/_{100}$ of the total flux of light produced by a source of one spherical candlepower.

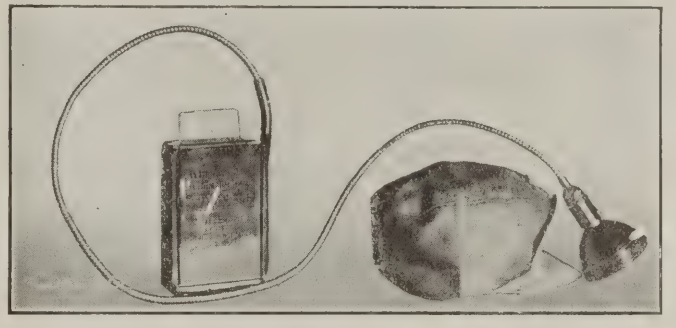
The term candlepower used without qualification is not only confusing but really meaningless. If all sources of light distributed light equally in all directions, then a single measurement of their candlepower would suffice to compare them. Practically, however, sources of light differ a great deal in the way they distribute light, and this is especially true if reflectors are used.

The Average Candlepower

Therefore, if a lamp is stated to give two candlepower, the statement should also explain whether "head-on" candlepower is meant, or average candlepower over the stream of light, or average candlepower in a given plane —such as, for instance, the horizontal. A lamp that uses a reflector may have a "head-on" candlepower 3 to 10 times the average candlepower over its entire stream of light. Generally it is best to state the average candlepower of a lamp instead of the candlepower at a single point or group of points.

A statement of the candlepower of a lamp does not sufficiently define its light-giving capacity. A 100-cp. lamp is seemingly 33 times as desirable as a 3-cp. lamp and yet a 100-cp. lamp shining through a hole ½ in. in diameter gives less actual light and much less useful light than a 3-cp. lamp shining through a hole 3 in. in diameter. Therefore, in order to define properly the light-giving capacity of a lamp, a statement must be made regarding both the candlepower and the total flux of light (or lumens) produced by the lamp.

The selection of proper lower limits for intensity of light and its flux is, aside from safety, the most important consideration in selecting portable electric lamps. Without these standards of reference accurate and intelligent comparison of lamps is not possible. In an attempt to establish such lower limits the bureau searched for some time for standards which should be fair, not too low in value, not arbitrarily selected, and which should bear an easily recognized relation to something already in use.



The Specifications Require Lamps Must Give at Least as Much Light as Wolf Safety Lamps with a Clean One-Inch Flame

It was finally decided to prepare a standard Wolf safety lamp to give its best performance and, after adjusting the flame height to 1 in., measure the average intensity of the stream of light and also the total flux of light in the stream. This was accordingly done at two different times, using different lamps, prepared by different men, and tested with different instruments of different types. The first measurements were made by Dr. L. O. Grondahl, of the Carnegie Institute of Technology, and the second measurements I made myself. The results of the two tests checked within a very few per cent.

The lamp used was a Wolf miner's safety lamp, 1907 model, round burner, burning 70-72° naphtha, and prepared and trimmed in accordance with the standard practice of the Bureau of Mines. The average intensity of light stream, as determined by these tests, was a trifle under 0.4 cp. and the total flux of light was found to be not quite 3 lumens.

Lower Limit of Cap Lamps Half That of Hand Lamps

The bureau therefore concluded that a satisfactory lower limit of flux of light for hand lamps would be 3.0 lumens and a satisfactory lower limit of average intensity would be 0.4 candlepower.

The Hirsch Cap Lamp

The bureau suggests that lamps designed to be worn upon the cap should give the same intensity of light as that required for hand lamps, but that the minimum flux of light required from cap lamps should be not more than half the minimum demanded from hand lamps, because when a lamp is worn upon the head any light that is thrown to the rear is wasted. If the equivalent of a safety lamp were mounted upon a man's head, one-half of its light would fall behind the man and thus could not be used. Therefore the bureau concluded that 1.5 lumens would be a satisfactory lower limit for the flux of light produced by a cap lamp.

Proper Time of Burning per Day

Twelve hours was selected by the bureau as a reasonable time of burning. This length of time was chosen after consultation with several people outside of the bureau, who were competent to express an opinion in regard to the subject.

The necessary daily time of burning of a lamp will not be everywhere the same, but when everything is considered, 12 hr. does not seem to be unduly long. A lamp should be able to give the required light up to the time when the exhausted condition of its battery requires that the discharge be stopped lest the battery be impaired. Therefore, at least an hour of burning should be allowed over and above the usual requirements of the miner in order not to push the battery too hard in an emergency and to allow for possible incomplete charging.

Deterioration of Electrolyte, Lamp Bulbs and Battery Plates

The only interruptions of service that can be regarded as reasonable are those incident to the renewal of such parts of the equipment as have an admittedly limited life, such as electrolyte, lamp bulbs and battery plates. The interruptions incident to changes of electrolyte need not

seriously interfere with the service of the lamp and it hardly seems necessary or desirable to place a limit on the frequency of such interruptions. The failure of lamp bulbs will not cause an appreciable interruption of service if the bulbs are changed when they grow dim and are not allowed to burn out altogether. The bureau believes that it is not unreasonable to require 300 hr. of actual service from each lamp bulb.

The most serious of the allowable interruptions of service will be caused by the failure of the battery plates. The bureau believes that it is not unreasonable to require of each battery plate the equivalent of 3600 hr. of actual service in 12-hr. shifts, when the service is completed within one year from the date of beginning.

Failure of Lamp Cord and Other Attachments

Interruptions in the service of cap lamps are also to be expected from the failure of the cord which connects the battery with the head piece. Although a reasonable time-of-service requirement can be placed upon this part of the equipment, there is no way other than actual service to determine whether or not a cord complies with the specifications. Any tests which might be suggested would be arbitrary in character and might be too severe, or too lenient.

Interruptions of service other than those just mentioned may be regarded as unreasonable and as reflecting upon the design and construction of the lamp equipment. Among such interruptions may be mentioned those resulting from failures of terminals and leads, battery jars, battery casings, contacts, etc., as well as any failures of bulbs or plates that occur before their specified time of service has expired.

It is manifest that every time a lamp bulb, a battery plate, or a cord is renewed, the cost of maintenance is increased. Therefore, from the standpoint of cost as well as from that of service, it is desirable that even reasonable renewals should be as few as possible.

The following specifications for the minimum performance of portable electric mine lamps are offered by the bureau for discussion and criticism:

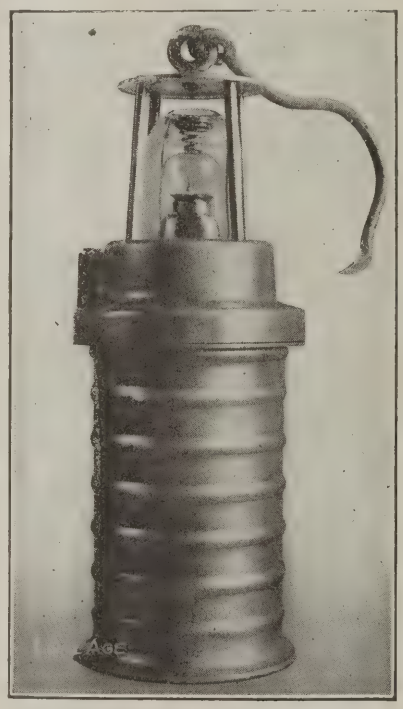
BUREAU OF MINES SPECIFICATIONS FOR PORTABLE ELECTRIC MINE LAMPS

The values stated are suggested minima for the items against which they are written

1.	Safety	100 per cent.
2.	Intensity of light at all times	0.4 cp.
3.	Flux of light at all times: For hand lamps	3.0 lumens
	For cap lamps	1.5 lumens
4.	Time of burning per charge	12 hr.
5.	Average life of bulbs	300 hr.
	(Not more than 5 per cent. to have less than 250 hr. life)	
6.	Average life of batteries	3600 hr.
7.	Variation in current consumption of bulbs,	10 per cent. from average
8.	Distribution of light	not here stated
9.	Angle of reflector	100 deg.
10.	Mechanical and electrical construction	first class

Further Explanation of the Specifications

The safety requirement is intended to cover freedom from gas ignition and from premature extinction. The bureau believes that lamps that have passed its tests and have been approved as permissible for use in gaseous mines will satisfy the requirements of safety. Where cap lamps are employed, the light stream, from which, occupies a solid angle of more than 180°, the flux of light shall be increased in proportion to the increase in the cross-section of the light stream.



Time of Burning

The time of burning, as stated here, is taken to mean the time during which the discharge voltage exceeds the lower limit established by the manufacturers, and the lamp is producing not less than the specified flux of light at a mean intensity of light not less than 0.4 cp.

Distribution of Light

Any requirement as to the distribution of light will, of course, apply only to lamps that use reflectors of some kind. No value is given in the table to this qualification because an intelligible statement requires considerable space. It is clearly desirable to have a uniform distribution of light and yet to make this requirement too rigid would entail unwarranted expense. The following is suggested as a reasonable specification which will preclude uneven distribution of an annoying or inefficient character:

The distribution of light shall be determined both by observation and by photometric measurement. The lamp shall be placed 3 ft. away from a plane surface which is perpendicular to the axis of the light stream of the lamp. When so placed the lamp shall illuminate a circular area not less than 7 ft. in diameter. All observations and measurements of distribution shall be referred to this 7-ft. circle, regardless of how large an area the lamp may illuminate.

The Ceag Hand Lamp

As observed with the eye there shall be no "black spots" within that circle nor any sharply contrasting areas of bright and faint illumination anywhere. As measured photometrically the distribution of light diametrically across the circle shall fulfill the following requirements:

The average illumination (in foot-candles) on the best illuminated $\frac{1}{10}$ of the diameter shall be not more than twice the average illumination throughout the diameter and, for at least 50 per cent. of the diameter, the illumination shall be not less than the average.

Reflector Angle

This refers, of course, to the solid angle of the stream of light. A reflector whose cone of light has an angle of 100 deg., will illuminate a circle about 7 ft. in diameter if placed 3 ft. away from the surface so illuminated.

Mechanical and Electrical Construction

It is not necessary to suggest to mining men that anything should be well made if it is to be used underground. Under this head should be considered simplicity of design, strength of parts and fastenings, design of moving and removable parts, and the design and construction of electrical circuits and contacts.

Secretary F. K. Lane on Public Coal Lands

SYNOPSIS—The report of Franklin K. Lane, Secretary of the Interior, to the President on the public coal lands and immediately allied subjects. He declares that Alaskan affairs should be administered by a board of appointed officials, that coal lands should be leased, not sold, in both the West and in Alaska, and that the present system of selling is inoperative and based on mere guesswork.

The largest body of unused and neglected land in the United States is Alaska. It is now nearly half a century since we purchased this territory, and it contains today less than 40,000 white inhabitants, less than 1000 for each year it has been in our possession. The purchase was made as a means of protection against the possible aggression of a foreign nation and without the hope that it would be even self-supporting. In the intervening 46 years we have given it little more than the most casual concern, yet its mines, fisheries and furs alone have added to our wealth the grand sum of $500,000,000.

We have withdrawn Alaska from the too aggressive and self-serving exploiter. What have we to substitute as a safer servant of public interest? To this question I have given much thought, and my conclusion is that if we are to bring Alaska into the early and full realization of her possibilities we must create a new piece of governmental machinery for the purpose. We should undertake the work in the spirit and after the method of a great corporation wishing to develop a large territory. In my judgment the way to deal with the problem of Alaskan resources is to establish a board of directors to have this work in charge.

POWERS OF BOARD OF MANAGEMENT

Into the hands of this board or commission I would give all the national assets in that territory, to be used primarily for her improvement—her lands, fisheries, Indians, Eskimos, seals, forests, mines, waterways, railroads—all that the nation owns, cares for, controls or regulates. Congress should determine in broad outline the policies which this board with liberal discretion should elaborate and administer; the board having powers similar to those enjoyed by that in the Philippines. This board would, of course, have nothing whatsoever to do with the internal affairs of the organized territory of Alaska, for it would exercise no powers save such as Congress granted over the property of the United States in Alaska.

There are several reasons which appeal to me as supporting this suggestion:

1. Such a board could advise Congress as to what should be done, without prejudice, out of a deep national interest and with firsthand knowledge of conditions.

2. Such a board would coördinate the present enterprises of the Government in Alaska. As it is now, the control of lands is in one department, of forests in another, of roads in another, of fisheries in a fourth, of railroads in still another. The care of black bear is in one department and of brown bear in another.

ABSENTEE GOVERNMENT

3. There can be no satisfactory administration of land laws nor any other laws at a distance of 5000 miles from the point of action. Much less is this possible where the two sections of the country are separated by an ocean and the land calling for attention is closed to the world one-half of the year. The eye that sees the need should be near the voice that gives the order.

4. Alaska's opening and improvement should be treated as one problem. Each step in such an administration should be part of a plan, not an isolated act. We should have a unified and consecutive program, based on immediate knowledge, governing this work. Each line of activity within the territory should be correlated with all other activities. The opening of lands and the building of railroads or wagon roads, for instance, should be part of one scheme.

RIGHT TO ITS OWN REVENUES

5. Alaska should be developed so far as possible out of her own revenues and resources. She should have a Federal budget of her own. Her revenues and expenditures should be presented to Congress on a single sheet. The funds raised from her lands and fisheries, her furs, her forests, and her mines should be used for the construction of her roads, railroads, telegraph and telephone lines, or for any other purpose which would make her resources more quickly available to the world. I believe it could be shown that Alaska is self-supporting today, or, what is more to the point, that by proper taxes and charges imposed upon those who are deriving large return from their enterprise in the territory, such revenue could be derived as would support a large policy of expansion and improvement.

The members of such a board appointed by the President would be selected presumably with reference to their fitness for the work to be done. Each one could be made the administrative and residentiary head of a department or division, so that there might be a commissioner of the Alaskan land office, another commissioner of highways, another, perhaps, commissioner of Indian affairs and fisheries, and so on. All would sit together, as in the commission form of municipal government, and would work for a common end, the upbuilding of Alaska as an integral and contributing part of the Union.

I apprehend the fear that with such a commission there would be danger of corruption or indifference creeping into its work. This, however, is incident to the bestowal of all authority. The commission would not go unchecked, of course, for it must report to the head of some department at Washington, and through that head to Congress, and would be always subject to investigation. Moreover, no method has yet been invented by which dishonesty or poor judgment can be guarded against in public or in private life. In the end the character and wisdom of the men appointed is the only insurance that can be given against conduct that is foolish or worse.

Alaska should not, in my judgment, be regarded as a mere storehouse of resources upon which the people of the States may draw. She has the potentialities of a state. And whatever policy may be adopted should look toward an Alaska of homes, of industries, and of an extended commerce.

Strongly as I would urge this method of management—for it offers a rare opportunity to exhibit the efficiency of a Republic—I would not have Alaska wait for needed legislation until the merits of such a plan could be passed upon by Congress. Those things which appeal to me as of immediate necessity upon which independent action may be taken are (1) the construction of railroads in the territory and (2) the opening of her coal lands.

ALASKAN RAILROADS

I have already expressed to the Congress my belief that it was wise for the Government itself to undertake the construction and operation of a system of trunk-line railroads in Alaska. And I am led to this view irrespective of the possibility of private enterprise undertaking such work, although my belief is that no railroads would be privately constructed in Alaska for many years to come excepting as adjuncts to some private enterprise. Be that as it may, it would seem wise for the Government to undertake this task upon grounds of state. The rates and the service of such railroads should be fixed with reference to Alaskan development—not with regard to immediate returns. The charges fixed should be lower for years to come than would justify private investment. I would build and operate these highways in the same spirit that the countries or the States build wagon roads—not for revenue, but for the general good.

ALASKAN COAL LAND

It is not necessary to set forth here the extent or character of the coal fields of Alaska. Neither could I add to your knowledge or that of Congress as to the need for this coal both by the Navy and by the industries and the people of the Pacific coast generally. There are almost unlimited quantities of a high grade of lignite in the interior which may not stand extended storage or transportation. This could be converted into electricity at the mouth of the mines and widely distributed for lighting, heat and power. Toward the southern coast of the peninsula there are two well known fields of a high-grade bituminous coal and some anthracite. These are the fields which have given rise to the troubles with which all are familiar.

These coal fields should be opened not to speculation, but to operators. Those should have these lands who will use them. None should be opened as a basis for a gamble in future values. If these premises express a sound public policy, there appears to me but one conclusion that can be

reached as to the manner in which they may safely be turned over to the public—under a leasing and royalty system similar to that under which the state of Minnesota leases its ore lands and the states of Montana and Colorado their coal territory.

EACH LEASEHOLD 2600 ACRES

The tracts opened should be disposed of to those who within a certain time would develop mines and make their product commercially available. This means that where a railroad is necessary to the operating of a mine the applicant should take a lease so conditioned for a limited period. Sufficient land should be leased as a body to justify long-continued and economical operation. As the average of all operations in the United States is 2600 acres, including many small holdings, this might be taken as a maximum unit.

There has been much dispute between those who favor making a lease for an indeterminate period, dependent alone upon continued operation, and those who believe it wisest to fix a term for the lease, 20, 30 or more years. This dispute seems to me of much more academic than practical interest. There should be no disposition to change the lessee. If a fixed term of leases is decided upon, the original lease should have an assured preferential right to a renewal until the mine is worked out. So that in the end the fixed term is a reservation of the right on the part of the Government to make new terms at the end of a number of years, a reservation which could be fixed in an indeterminate lease.

A fixed minimum annual royalty would conduce to operation and prevent the holding of lands out of use. These are matters, however, of regulation upon which much thought should be expended, and the experience of other lands will be found helpful. If the principle of the homestead law is adopted, and one lease only permitted to any one person or group of persons, and all leases made nontransferable, excepting with the consent of a designated authority, it would seem that monopoly could be prevented. I would, however, add one other precaution—that in each field a large body of the coal land be reserved, so that the public and the Navy might be rendered independent of private supplies if that should become necessary.

ADVANTAGES OF LEASEHOLDS

The attraction of a leasing system is that it enables an operator to put all of his capital into the promotion of his enterprise, no investment being needed for the purchase of the land. This makes it possible for the man of comparatively small means to become a coal-mine operator. The lessee is pleased to pay the Government a royalty in lieu of tying up a large amount of capital in the land itself.

There is this further consideration, which those interested in Alaska's future might well consider. The royalties arising from these mines (as well as from oil) would for a long time be a source of revenue to the Government. To stimulate the opening of mines, all royalty might well be waived for a brief period; later, however, these royalties would be a not inconsiderable addition to the resources available for Alaskan development, for I would think it the wisest policy to give to this new land the full return from her properties to be used in her improvement, at least for many years.

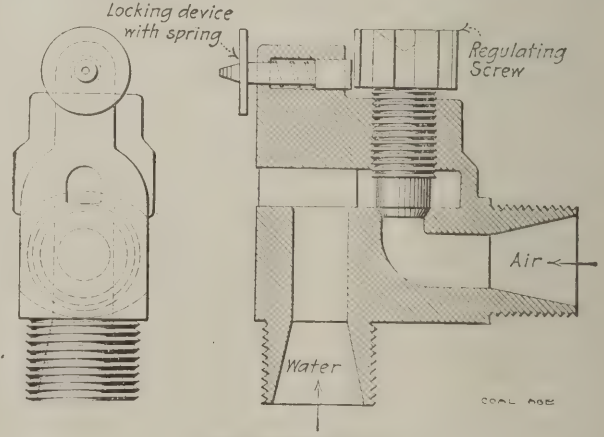
There are many isolated places in Alaska where small mines may be opened to supply a local and restricted need. A license to mine a small acreage without any charge whatever on the part of the Government would meet this demand.

WESTERN COAL LANDS ARE NOT SELLING

It might be well at this point to consider the coal-land situation in the Western States. For the policy I have suggested as advisable to apply in Alaska I think the sensible policy to adopt throughout the rest of the country. We have tried two experiments in the United States as to coal lands. We allowed our coal lands to slip from us under the old land-is-land policy until we came into the presence of a coal monopoly or a series of such monopolies in various parts of the country. If this is questioned we may at least say, with exactness, that we realized that we had been putting priceless assets into the hands of a comparatively few far-sighted men for an inconsiderable consideration. Then we tried the other plan of appraising such properties on a scientific estimate of contents upon which the land is sold. This is the present plan, and it is really nothing more than a demand for a full but discounted royalty in advance. It has against it, in my opinion, at least two objections. Our coal land is not being used under this plan save under exceptional conditions of local and immediate demand, and the purchaser, when there is one, is speculating on the best guess that an honest geologist can make as to the amount of coal in the ground.

The outstanding withdrawals of public lands valuable for mineral fuels and fertilizers or in connection with the water resources of the public domain now aggregate 66,000,000 acres. The coal-land withdrawals awaiting classification constitute the larger part of this acreage, being 56,316,410 acres on Dec. 4, not including the blanket withdrawal of coal lands in Alaska. It is noteworthy that a larger area than this has been restored within the past five years, and nearly 20,000,000 acres have been classified as coal lands and are open to entry at appraised prices. The lands classified and restored by Executive order to appropriate entry since Mar. 4 last, total 10,000,000 acres, every restoration being based upon careful consideration within this department. About 400,000 acres of mineral lands in the same nine months have been withdrawn.

COMPETITION INVOLVES WASTE



It is certainly not for the public interest that our coal deposits shall be opened rapidly and ruthlessly. We may reforest lands that have been devastated, or feed again into fruitfulness a soil that is starved, but we cannot replace the carbon deposits underground once they are removed. I cannot, however, feel that we should sacrifice any present need for fuel or willingly surrender ourselves to a demand for exorbitant prices because of a fear that some day the coal supply may be exhausted. Already there has been developed a substitute for coal in the flowing stream. The turbine converts melted snow into heat and light, which can be distributed over a constantly widening area.

I think we have now arrived at that point in scientific achievement which justifies the belief that the wheels of industry will not cease, nor our houses go unlighted or unheated, so long as dams may be built upon our streams. Water will be, indeed already is, the greatest conservator of coal. We must seek to make use of our coal, the fullest use that society requires. This principle seems a truism. But here lies the difficulty. We wish cheap coal and at the same time a minimum of waste. We wish society to take the lion's share of the profit and yield no more to the operator than will make his work sufficiently attractive to keep him at it. In short, we desire competition without waste, a frank impossibility.

Other countries have wrestled with this problem. Some have gone into Government operation. But those who are nearest to us in institutions and tendencies have found that in a new country where there must be large development and higher rewards for enterprise, the safest practicable method is to lease the land, the Government taking a modest royalty and retaining some measure of control over operation.

A Water Spray for Drills

Considerable attention has been paid recently to the danger to which a miner is exposed in breathing in air laden with stone dust when engaged in drilling through hard rock. Such inhalation of stone dust may cause serious lung trouble. It is interesting, therefore, to learn that the Hardy Patent Pick Co., Ltd., of Sheffield, England, is fitting on some of its drills an ingenious form of water spray which avoids the danger of the dust-laden air.

THE SPRAY NOZZLE

This arrangement is both simple and efficient. It is attached to the air pipe of the drill, and the escape of air through a minute independent outlet sucks up and atom-

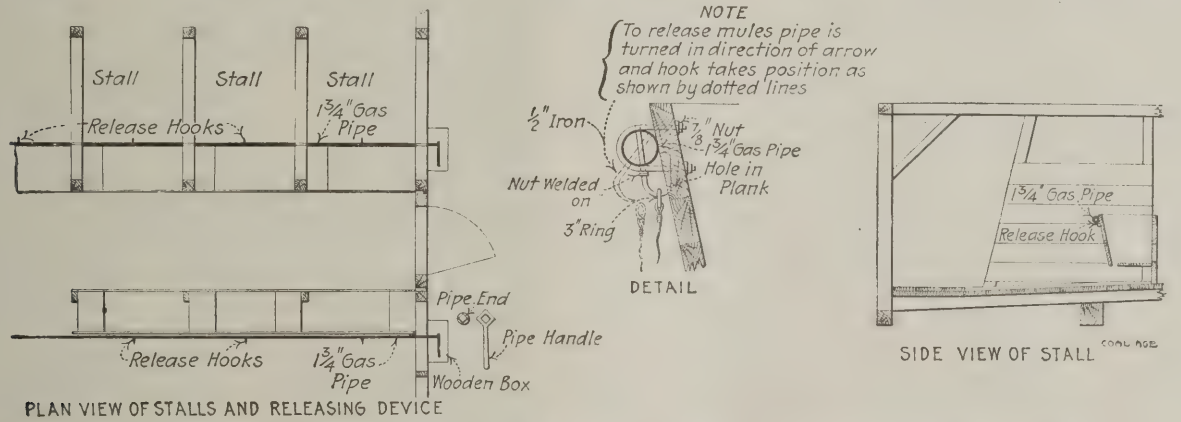
izes a small stream of water, projecting the latter as a fine spray into or across the hole being drilled. In this way practically all the dust formed by the drill is successfully allayed.

Water under pressure is not required and hence an ordinary bucket is all that is needed in the way of a receptacle. One pail of water is found sufficient for 8 to 10 holes in ordinary material. By a regulating screw and spring-locking device, the amount of spray can be easily adjusted to meet all requirements.

Coal Freight Rates from the Hocking District

While the Ohio legislature, ably seconded by the Govenor has been busily engaged on drastic legislation, adverse to the operating interests in the state, we are pleased to note that the state officials are as vigorously championing the cause of the local trade against foreign intrusion. Thus we note that alleged discrimination by the Hocking Valley R.R. against Ohio coal shippers, in competition with West Virginia operators has been taken in hand by Governor Cox. He has ordered the public-utilities commission to take immediate action in fixing a rate which will, if possible, enable operators of the Hocking Valley district to compete with the West Virginia mines.

According to Senator J. B. Dollison, of Logan, who conferred with the Governor, many mines in the Hocking district have been closed down because they are unable to compete with West Virginia, by reason of discriminatory freight rates. The rate per ton from Nelsonville to the docks at Toledo is 80c. according to Senator Dollison. West Virginia coal, delivered to the Hocking Valley by the Kanawha & Michigan R.R. at Armitage (a 12 miles further haul than from Nelsonville) is carried to the Toledo docks for 40c. a ton. Thus for a 12 miles shorter haul, the Hocking Valley charges the operators 40c. more per ton than the West Virginia companies.



The railroad company is said to demand the higher rate from Ohio operators because it has to assemble the cars for the Ohio shippers, while this is not necessary for the coal that is delivered to it from the Kanawha & Michigan at Armitage. The full train already "made up" is turned over to the Hocking Valley, and all the latter has to do is to haul it to the Toledo docks.

Hocking Valley coal operators say they can compete successfully with the West Virginia operators if a reduction in the Nelsonville rate to 67c. per ton is fixed. At this rate, it is alleged the railroad company would be making an extra profit of 17c. per ton off the Ohio operators, as the utilities commission has fixed a rate of 10c. a ton for assembling or "making up" a train of coal cars.

Emergency Unhitching Device

The *Employee's Magazine* of the Lehigh Valley Coal Co. describes a device which released all the 43 mules from their stalls by a single turn of a handle in the old barn of the Centralia colliery early Sunday morning, Sept. 21, when the building caught fire. A mere turn of a handle at either end of the barn releases simultaneously all the chains attached to the animals, and thus enables them to be driven from their stalls with the least possible delay.

The accompanying sketch shows the arrangement and operation of this device. It consists of a long wrought-iron gas-pipe 1¾ in. in diameter, extending from end to end of the building, and passing through all the stalls. The pipe is held firmly in place against the front of the mangers by ⅞-in. iron rods, secured with ⅞-in. nuts and washers. In each stall and passing through the middle of the pipe is a ⅞-in. iron rod fastened with a lug and welded nut and bent like a hook, with its point resting in a slight depression in the plank. On this hook is placed a 3-in. ring that holds the clip or cross piece fixed on the end of the halter chain attached to the animal.

A Device for Unhitching All the Mules in a Row of Stalls at One Operation

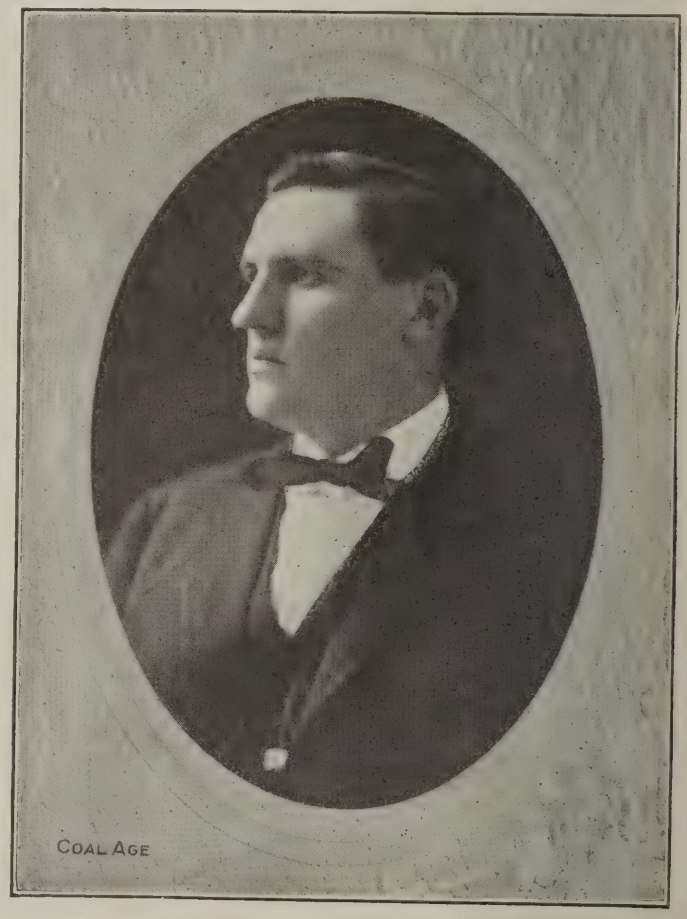
It is a simple matter to remove the clip or cross-piece from the ring when only one animal at a time is to be released. In case of emergency, however, when it is extremely urgent to unhitch or release all the animals at once in order to remove them as quickly as possible from the stable, the end of the pipe is given about a quarter of a turn, and all the hooks turning with the pipe will move back, thereby permitting the rings to slip off and thus release all the animals at the same time.

At least 100 cubic feet of air per minute should be allowed for each man in the mine and 500 feet per minute for each animal. In the anthracite district of Pennsylvania 200 cubic feet per minute is required. If the mine makes inflammable gas, there should always be allowed at least 150 cu.ft. of air per minute for each person. There should be a separate split of air for every 50 to 100 men, depending on the laws in force in the state where the mine is located. By this provision, air is supplied without excessive velocity and the products of an explosion in one section may not invade another.

Who's Who--In Coal Mining

Every movement centers around some personality, for there is no such thing as impersonal development in human affairs. Every new mental attitude, humanitarian, intellectual, financial or what not, clothes itself in a man for without such a visible presentation, the movement seems too abstract for acceptance. There are a few people who declare themselves for principles and decry persons, but in the end the principles of the persons are more important and more forceful than either.

The American Mine Safety Association has come to the point where it needs and must have a leader. Hitherto, it has been ably fostered by the Bureau of Mines, in the person of H. M. Wilson, but whether it does or does not do in the future what is expected of it, depends on whether it finds, somewhere, a man around whom its activities can in the future be developed.



And that man it trusts it has found in John P. Reese of Gillespie, Ill., its second president. It will be difficult to make this movement a success, for the heterogeny of elements entering into membership makes its progress difficult. The medical men who must debate the subject of first-aid methods, the rescue experts who must decide on the right manner of mine recovery, the managers and superintendents who must discuss accident prevention, and the miners whose interest must be stimulated by contests, together combine to make the problem of the chair, most varied and difficult. But if the work be accomplished at all it will be by reason of its appeal to every element in the industry.

Mr. Reese is not a professional philanthropist full of statistics and sighs whose business is to lament that other people do not live as justly as he would if placed under like conditions. In fact, he does not lay claim to any such superiority and would be slow to acknowledge, doubtless, what is undoubtedly true and that is that he has, as a result of his experience, a broader comprehension than others of the needs of men less fortunately circumstanced than himself. Large of frame, cheerful in mind, buoyant in spirits, he impresses you as a philosopher despite himself, and the work he will do will be as virile in character as suits a man thus constituted.

In fact, the work to be performed is hardly sentimental for the liability laws have transformed safety prevention in most states from a philanthropy into an economy, and have put life conservation on a plain "bread-and-butter" basis. The operator is not only admonished to see that he does not offend but also compelled to make sure that the employee himself does not break the rules of safety, for in either case he must pay and usually heavily.

John P. Reese was born of Welsh parents, at Sodom, Trumble County, Ohio, Jan. 14, 1877. His father, who was a coal miner in his native land, came to Ohio from Wales in 1872. The family moved to Shawnee in the same state when John was two years old. His father died in 1883, leaving a large family of small children with no visible means of support; but the mother, a hard-working, honest, Christian woman, succeeded in giving them good training, though much schooling was out of the question.

John started to work at the mines in Shawnee, Ohio, when he was 9½ years old, and with the exception of 2½ years (between 16½ and 19 years of age) when he worked as a brakeman, he has remained in the industry ever since. Despite 10 hr. of mine service every day, he attended night school for several winters. At the age of 13 yr. he was the sole support of his widowed mother and three younger children, and so continued till he reached 21 yr. of age when he married a school teacher at Hiteman by the name of Blanche Ghrist.

JOHN P. REESE

He was then employed as checkweighman and held at different times the office of local president and state vice-president of the United Mine Workers of America. He does not hesitate to credit his wife and mother with whatever success he has had in life. His sympathies have always been with the "union," to which he has belonged from a boy. He joined the Brotherhood of Railroad Trainmen when engaged as a brakeman and kept up his dues till the Iowa miners were organized into the U. M. W. of A. in 1898 with his active assistance.

Since that time he has been vice-president and president of the Iowa district and a member of the National

Executive Board of the U. M. W. of A. He resigned his Iowa presidency in 1902 and ran for congressman on the Democratic ticket in the sixth Iowa district and was naturally defeated in that stronghold of Republicanism.

So renouncing his congressional ambitions, he served for several years as commissioner and secretary for the Iowa Coal Operators Association resigning in 1908 to become assistant superintendent of the Consolidation Coal Co., at Buxton, Iowa. In 1909, he became president and general manager of the Ogden Coal Co., at Ogden, Iowa, and in January, 1910, he returned to the Iowa Coal Operators' Association as president and chief commissioner, but he resigned on Oct. 1 of the same year to accept his present position as general superintendent of the Superior Coal Co., of Gillespie, Ill.

On Sept. 1, 1912, his jurisdiction was extended over the Consolidation Coal Co.'s mines at Buxton, Iowa, and his title is now general superintendent of the coal properties of the Chicago & Northwestern Ry. Co. Their mines are the largest producers in Illinois and Iowa.

Mr. Reese has been elected president of the Mining Institute of Illinois. He has, of course, several business connections being vice-president of the Coyne-Reese Drill Co., of Des Moines, Iowa, director of the Home Savings Bank of that city, and of the Ogden Coal Co. Happiest when in company, he belongs to several fraternal organizations and clubs, but his greatest delight is in his Gillespie home with his daughter of 14 years and his son of 12.

If the American Mine Safety Association is to find a man who has a broader sympathy with all concerned in the mine-safety movement, it will have to look far afield. A good talker and *raconteur,* a cheerful whole-souled fellow, a man with knowledge of both pick and pay roll, he should be able to arouse the necessary interest and enthusiasm and put the association on a firm working basis.

Concussion as a Cause of Explosions

SYNOPSIS—Inflammations of coal dust and air are propagated by burning gas but in explosions the coal is burned as a whole and not merely distilled. A big blower of gas will not raise a dust cloud but projected into such a cloud 150 ft. long, it will propagate with low pressures and will probably under favoring conditions develop a most violent explosion.

In the combustion of gaseous mixtures, there is no well defined border line between inflammation and explosion, the two terms being employed merely to indicate differences in the rapidity of combustion. But in the burning of mixtures of coal dust and air, it appears possible, and indeed necessary, to draw a line of distinction between inflammation and explosive combustion.

The "explosion-wave" in gases—the most rapid form of combustion—is, however, of a different character from ordinary combustion. The rate of travel of the explosion-wave is a definite physical constant for any particular mixture of gases in which it can be set up. Fortunately, it does not appear possible to produce the explosion-wave in mixtures of firedamp and air, or of coal dust and air.

Inflammation and Explosion of Coal Dust Defined

Put briefly, our view is that during an inflammation of coal dust (at all events from bituminous coals) the flame is propagated largely by the burning of gases distilled from the dust; whereas during explosive combustion the portion of each dust particle which aids in propagating the flame is burned as a whole, both the volatile matter and the fixed carbon being consumed.

Fundamentally there appears to be no reason why the inflammation of mixtures of combustible dust and air should not produce results of the same nature as those observed during the inflammation of gaseous mixtures, for in both cases the phenomena are the results of rapid combustion.

The more finely divided the combustible dust, the more nearly does it approach to the condition of a gas or vapor, and, if of sufficient lightness to remain in suspension in the air and thus form an intimate mixture with it, there seems to be no reason why a flame once started in such a mixture should not be propagated throughout its extent—it being presumed that the dust can be inflamed readily.

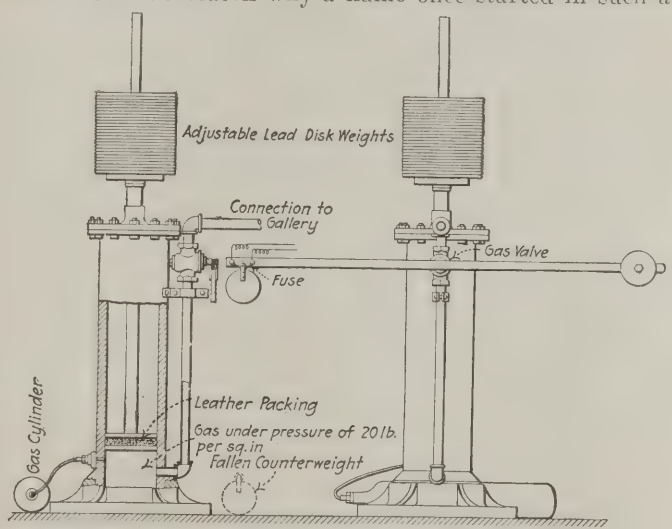


Fig. 1. Device for Regulating Gas Emission

Difference between Gas and Inflammable Dust

In making comparison, however, between the combustion of a gas, such as methane, and that of particles of coal dust, the great difference in size of gaseous molecules compared with that of dust particles must be borne in mind.

If it be assumed, for example, that a coal-dust particle has a diameter of $\frac{1}{1000}$ mm., about $\frac{1}{25000}$ of an inch, this is over 3000 times the computed diameter of a molecule of oxygen. Moreover, gas molecules are always in

Note—An abstract from the fourth report of the British Explosions in Mines Committee, signed by Sir Henry Cunyghame, R. A. S. Redmayne, A. P. H. Desborough, H. B. Dixon, and W. C. Blackett.

very rapid motion, the mean speed of oxygen molecules at ordinary temperature and pressure being about 425 m. or about 1394 ft. per sec. Compared with this speed, that of the floating dust particle is inappreciable. Such a dust mote floating among oxygen molecules might, perhaps, be compared to a balloon lashed by a storm of hailstones.

Similarities in Explosive Characteristics of Gas and Coal Dust

Despite the difference in size of the reacting bodies, however, there are several analogies which may be drawn between explosions of gaseous mixtures and of mixtures of a combustible dust and air.

As in the case of gaseous mixtures, there will be a definite ignition temperature for each kind of dust and air mixture, and inflammation will not be propagated unless and until each successive "layer" of the mixture has been raised to that ignition temperature.

Similarly, there will be a "lower limit" as regards the quantity of any given dust which must be in suspension in the air to enable self-propagation of flame to take place.

How an Inflammation Is Propagated

When considering the question of the *propagation* of the initial inflammation of coal dust the nature of the means of ignition must not be overlooked.

If a previously formed dust cloud in the air be presumed, it can be taken for granted, on *a priori* grounds, that, once ignition of a sufficient volume of the cloud has been effected, no matter by what means, propagation of the flame will take place throughout the cloud if the fineness of the dust, the quantity of dust in suspension, and its ignition temperature are suitable.

In a mine explosion, however, a dust cloud does not necessarily exist ready formed; but the cause of inflammation has, in most cases, to produce the dust cloud simultaneously by disturbance of the air. In such cases, therefore, where the dust is not already in suspension, both flame and *concussion* are necessary for the initiation of more than a purely local inflammation.

For the propagation of flame in a mine, therefore, it appears to be essential that (1) a ready formed dense cloud should be present for a considerable distance along the roadway; or that (2) the source of heat which causes ignition should also create a disturbance of the air and thus raise in suspension deposited dust.

The Effect of Eddies on an Explosion

When the inflammation occurs and the flame proceeds along a gallery, the expansion of the gaseous products of combustion causes a movement of a column of air which is pushed forward in front of the flame. The opposition to this movement may be approximately calculated for a smooth gallery, since it depends on the inertia of the air to be moved, or the velocity of the air pushed forward, and on the size of the tube.

But in the roadway of a mine this opposition may be enormously increased by the irregularities and obstructions which cause waves and eddies in the air. A cloud of dust so compressed and disturbed burns with greater rapidity than in still air. The effect on the intensity of the advancing flame is thus cumulative. It may therefore be true that after the flame has proceeded a certain distance in the ready formed dust cloud, the column of air driven in front of the flame is capable of raising the dust lying on the floor and other surfaces, and so creating an inflammable cloud, independently of any other source of disturbance.

The Pioneering Dust Cloud

This conception of the manner in which an inflammation of coal dust and air is capable of increasing in intensity and of propagating itself throughout any length of roadway containing at the outset dust, merely deposited and not suspended is due, we believe, to W. C.

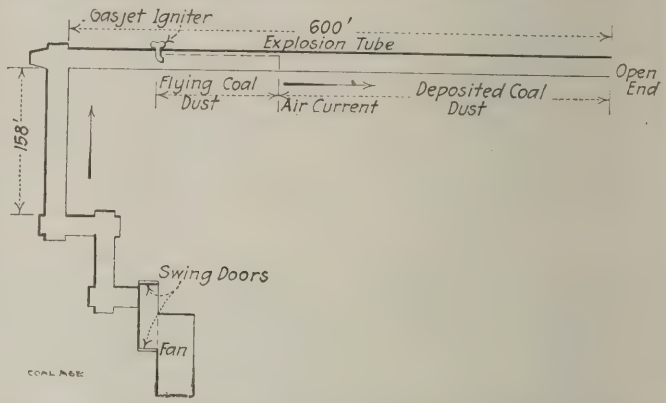

Fig. 2. Arrangement of Gallery to Show under What Conditions an Explosion Can Be Started by Flame in a Dusty Atmosphere

Blackett, who, from a study of the conditions existing in the Seaham, Tudhoe, Trimdon Grange and Usworth collieries, after the disastrous explosions which occurred there formulated his theory of a "pioneering cloud."*

This theory was founded, as aforesaid, on practical experience obtained during the course of investigations made *after* colliery "explosions." It remained to be seen how far it was borne out by what takes place *during* experimental inflammations on a large scale.

Explosions without Initial Concussion

A number of experiments for the purpose of obtaining information on this question were made by Doctor Wheeler for the Mining Association in the Altofts gallery. The results, which are given below, have not hitherto been published.

Arrangements were made by which dust clouds of different extent could be ignited by a large gas flame, unaccompanied by any concussion. The general arrangement for these experiments is shown in Fig. 2. The gallery (the Altofts gallery) consisted of a wrought-iron tube 7½ ft. in diameter and 600 ft. long. One end was open to the air and the other was joined, by means of a series of right-angle bends, to a fan. For a more detailed description of this gallery the "Record" of the Mining Association should be consulted.

The igniting arrangement is shown in Fig. 1. It consisted of a vertical cylinder, of about 2 cu.ft. capacity, fitted with a weighted piston. This cylinder was filled with coal gas under a pressure of 20 lb. per square inch, the pressure being obtained by weighting the piston with lead disks placed on a platform carried by the piston rod.

An outlet tube from the bottom of the cylinder was bent upward at right angles and closed at the top by an

*Vide "The Combustion of Oxygen and Coal Dust in Mines," Transactions Federated Mining Engineers, Vol. 7, p. 54, 1894. See also Proceedings of the National Association of Colliery Managers, March, 1891.

electrically controlled valve. Beyond the valve, the outlet tube was continued through the side of the gallery (as indicated in Fig. 2), and ended in a 2-in. nozzle fixed centrally in the gallery and directed toward its open end.

A Blower of Gas Fails to Cause Explosion

Just before an experiment, sparks from an induction coil were passed across the nozzle of the tube inside the gallery. When the valve on the cylinder was released, the weighted piston fell and forced out the coal gas which was then ignited by the induction-coil sparks at the nozzle. A large jet of flame was thus produced, from 10 to 14 ft. long and about 1 ft. in diameter at its widest part, resembling an ignited "blower" of firedamp. No unburnt gas escaped into the gallery.

After numerous trials it was found that with a 2-in. nozzle, and with the gas under a pressure in the cylinder of 20 lb. per sq.in., immediate ignition by the induction-coil sparks was obtained when the valve was released. A smaller nozzle gave a longer flame but ignition of the gas was uncertain.

Adding Coal Dust to Blower

A large flame of this nature (unaccompanied by concussion) was found capable of igniting a ready formed cloud of coal dust, but was unable to propagate flame for any considerable distance when the coal dust was simply placed in a heap in its path. It was, therefore, necessary to create beforehand a dust cloud over a certain distance, into which the flame from the igniter could be projected.

This was done by spreading the dust on thin horizontal boards, 6 in. wide and 12 ft. long, suspended from the roof of the gallery and extending end to end over a distance of 150 ft. from the igniter toward the open end of the gallery. These boards, which hung about 8 in. below the roof, were caused to fall simultaneously, at the same instant as the gas flame was produced, by the release of electrically controlled catches; and, after falling 6 in., still in a horizontal position, were suddenly jerked over sideways, so that the dust resting on them was projected into the air. In this manner a ready formed dust cloud was produced extending 150 ft.

The Dust and Gas Raise a Pioneering Cloud

Beyond this 150 ft. of previously formed cloud, the coal dust was simply deposited on the floor of the gallery over the distance remaining to its open end, namely, 350 ft. The coal dust, which was obtained by pulverizing Altofts silkstone nut coal, was present throughout in quantity corresponding to 0.4 oz. per cubic foot of air space.

A current of air, of insufficient velocity to disturb the dust deposited on the boards, was forced toward the open end of the gallery during each experiment.

Three tests were made in this manner. In one of them the flame traveled only 200 ft. from the point of ignition; that is to say, only 50 ft. beyond the distance over which the ready formed dust cloud extended. In the other two experiments the flame traveled the whole length of the gallery, and issued 115 ft. out of the open end into the air, the average velocity over successive distances of 100 ft. slightly increasing.

The Absence of Preliminary Concussion Makes Explosion Feeble

It is thus apparent that if an inflammation which is initiated without concussion takes place in a gallery along which for a certain distance a ready formed dust cloud extends, sufficient force is developed at the end of this cloud to raise in suspension deposited dust, in advance of the flame, so that the propagation of inflammation is continued.

Very little pressure, less than 2 lb. per square inch, was produced by the inflammation in any of the three experiments; and there was a temporary slackening in the rate of progress of the flame along the gallery where it came to the end of the ready formed dust cloud. Perhaps 150 ft. is about the minimum length, with the quantity of dust employed, of a ready formed dust cloud which will insure self-propagation of flame; just sufficient force being then developed, or rather, a just sufficiently *rapid* disturbance of the air being then produced, to raise dormant dust in advance of the flame. Three experiments in which the ready formed dust cloud was in existence over only 100 ft. from the point of ignition all failed to propagate flame beyond that 100 ft.

However, Concussion Is Not Needed to Produce an Explosion

These results appear to establish the fact that for a propagating inflammation to take place in a mine, the concussion of a blown-out or overcharged shot, or of a firedamp explosion, is not essential. Given a ready formed dust cloud of a certain extent, a flame, without any concussion, can ignite the dust and the resulting inflammation will spread through the cloud, the rapidity of combustion increasing as it travels. Ultimately, if the conditions remain favorable to the "pioneering phenomena," the "inflammation" will give place to "explosive combustion" in the manner explained in the ensuing section of this report. These conclusions are supported by further experiments now in progress, the results of which will shortly be reported.

Powder in Open-Cut Mining

Open-cut mining in the Pittsburg coal field of southeastern Kansas was first done by scrapers and horses. Three years and a half ago Miller and Durkee introduced a steam shovel for the purpose. It has proved a success, but in the last few weeks the shovel operators have learned to use blasting powder to help the shovels.

C. H. Markham is the only steam shoveler using powder up to the present date in stripping. Others have held back because of the inconvenience of boring the holes for the powder. These must usually be 18 to 30 ft. deep, and a drill for this purpose is bunglesome and difficult to handle. However, Markham is perfecting a drilling apparatus that will probably make the sinking of holes a one-man job.

Markham has found the use of blasting powder valuable in expediting the work of the steam shovel and for saving the hardest wear and tear on the ponderous machinery. This means that the cost of production is reduced. He is one of those who are making money. The overburden in the stripping field contains a couple of feet or so of hard shale. Many miners affirm having seen blue smoke from the friction of shovel-dipper and shale. The big machines rock terrifically in cutting through this material. The steel beams of their underwork have been known to crystallize from the vibrations and break, which naturally adds materially to the operating cost.

LOADING THE HOLES WITH 2500 LB. OF POWDER

Markham's blasting has been similar to that done extensively by Edward Evans, of Cherokee County, Kan., and by J. J. Lavery, near Liberal, Mo., not far from Pittsburg. The latter recently made a blast with 2500 lb. of powder at a single time.

ONE HUNDRED KEGS OF POWDER USED IN ONE PIT

He had a pit 18 ft. deep which he had been working with horses and scrapers. It was 500 ft. long, or in other words, the face was of that measurement. Fifteen feet

THE SHOT

back from the face he sank 18 holes, which were 24 ft. apart and 15 ft. deep. These were sprung, first with two sticks, then four sticks and at last with six sticks of dynamite, making 12 sticks in all. This work required about two or three hours. Exactly 100 kegs of Hercules 4F blasting powder were used, and Charles B. Spicer, Pittsburg, agent for this explosive, used an electric firing apparatus with which to discharge the shot. Workmen began springing the holes when Spicer reached the pit at 9 o'clock in the morning, and he left the work completed, at 3 p.m. He said that were he directing another shot of this kind he would recommend that the holes be 20 ft. apart only, when circumstances are as above described.

The shot made a pit 30 ft. wide, or a little more, as the blast broke the shale covering a little more than 15 ft. on the inner side of the face. A fair percentage of the dirt was thrown far enough to one side to make it unnecessary to move it further. Mr. Lavery says: "The cost of getting coal out of a strip pit with teams and scrapers probably isn't as cheap as with steam shovels, but the blasting as I did it will save a lot of labor and reduce the cost of production."

If this is true with teams and scrapers it is argued that it must be true with steam shovels, as such machines could probably work twice as fast with the overlay loosened up. Besides, the cost of maintenance of a better treated shovel would not be so high.

The Lavery pit works from 20 to 40 teams, with wages for man and horses at $3 a day and up, depending on the work done. Expenses per day are $100 up. The cost of the shot was $118.

THE RESULT OF THE BLAST

The Sacrifice!

BY BERTON BRALEY

Written expressly for Coal Age

Here are two men dead in a barroom brawl,
Two men who shouldn't have died at all,
Two husky miners we shouldn't lose,
Who lie here, lifeless, because of booze.
And their kids can cry and their wives can wail;
Yet here they huddle, two good, strong men,
And never a sound or a friendly hail
Can bring these miners to life again!

They were bosom pals when they came tonight,
Who drank together in all good will,
Till the whiskey put their brains to flight
And roused them to quarrel and row and fight
And drove them, at last, to kill!

So the knives came out as the drink poured in,
Burning each man with the fires of sin,
Searing them deep with wrath and hate
And all the passions fresh-come from Hell,
Till the knives flashed free and the blades struck straight
And one man stumbled—the other fell
In a pool of blood on the barroom floor
And neither one stirred when the fight was o'er.

Now it wasn't hate or a bloody feud
But a deadly madness the whiskey brewed,
And we've lost two men in a drunken strife,
Two brave, strong men in the prime of life,
Each with his children and home and wife!
They never will drill a hole again,
They never will joke with the other men,
They never will come through the deepening gloam
To greet their kiddies and wives at home!

They're dead and done for because of drink
—But still we hark to the glasses' clink,
As the barkeep says, with a smile so free
"Speak up now, gentlemen, what'll it be?"

Editorials

The Legality of Unions

The United States Circuit Court of Appeals has affirmed the judgment of the Connecticut District Court in the famous Danbury hatters case, but those who hope that unions will be declared illegal will gain but little comfort from the decision. It appears that the commodity, labor, can be made the subject of trust regulation without anyone being responsible before the law. This decision would not trouble us much, if we did not think that this viewpoint arose in the courts from fear of the danger which would accompany a contrary decision, and from the fact that in most, if not every county, the lawyers have a union of their own which somewhat effectually sets a minimum price for legal services.

Judge Coxe states in the decision to which we have referred that: "No one disputes the proposition that labor unions are lawful. All must admit that they are not only lawful, but highly beneficial when legally and fairly conducted, but like other combinations, irrespective of their objects and purposes, they must obey the law."

We conceive, therefore, that working men may combine to raise wages, improve working conditions, or to restrict hours of work, and so forth, and can, in this way, legally influence the price of products on the market. We conclude, therefore, that the objection of the judge is to such boycotting as that of which the United Hatters of North America have been guilty.

The declaration of the judge that "no one disputes the proposition that labor unions are lawful," is amazing. It has been quite generally disputed, and we have always been surprised that judges will permit the rules of lawyers, doctors and others to be produced in court as evidence that certain charges to clients are reasonable. For such rules are like union scales in restraint of the freedom of trade.

But those operators who are in union states are to be congratulated that the judges seem to take the view that labor is not a commodity of commerce coming under the Sherman act. Such operators are engaged in a criminal conspiracy to regulate the price of labor if the miners are engaged in a like conspiracy. If the law is once declared and affirmed to apply to labor unions in their regulation of the price of labor, it may be applied to organizations of operators for the same purpose. As the members of the latter have money, they can be made to pay damages. The miners having little or none cannot. So it is like a game of poker, where one man has money and another has not. The poor man cannot lose and the rich man may.

There is some cheer in the following words of Judge Coxe:

> That the anti-trust act is applicable to such combinations (unions) is no longer debatable. The law makes no distinction between the classes, employers or employees, corporations or individuals. Rich and poor alike are included under its terms. The Supreme Court particularly points out that, although Congress was frequently importuned to exempt farmers' organizations and labor unions from its provisions, these efforts all failed and the act still remains.

We have yet to determine, of course, by several cases in the courts just what labor unions may and may not do. But it seems clear that as far as that United States Circuit Court of Appeals is concerned, the workingmen may legally form unions to raise wages.

The Report of the Secretary of the Interior

It is sometimes unfortunate to be only a citizen and not in the official class. We have to take such information as is vouchsafed us and endeavor to make it meet our ends.

Some time ago, the Director of the Geological Survey and his able lieutenant on the Land Classification Board, wrote us complaining of a statement we had made. We made a retraction but we were not able then to determine definitely whether we accepted in lieu of ours, the figures submitted. So very frankly, we admitted that we could not say whether we accepted them or not.

When recently we met a representative of the Geological Survey, he declared this noncommital statement, a shameless innuendo, and advised us to apply to the Survey for more figures whereby we might frame a retraction or an indictment. We have written to the Survey and we are still in the dark.

Let us, therefore, lay down in black and white our manner of reasoning and leave to our readers to judge whether we truly lined out the fact in writing the innuendo to which reference was made.

As a preliminary, to make the facts clear to the general reader, we quote George H. Ashley, in his bulletin on the "Valuation of Coal Lands," who says:

> Prior to July, 1906, it was the practice to dispose of coal lands at the minimum prices fixed by the law, viz.: $20 per acre for lands within 15 miles of a completed railroad and $10 per acre beyond the 15-mile limit. Since that date, lands which have been classified and valued have been disposed of at fixed prices based upon the value of the coal in the land.

On the strength of this change, George Otis Smith ventures, on p. 332, of his report for 1912, to give the following table:

SALES OF COAL LANDS AT ALL PRICES IN THE UNITED STATES EXCLUSIVE OF ALASKA FROM 1903 TO 1911

Fiscal Year	Entries	Acres	Receipts	Average Price per Acre
1903–4	190	28,827.42	$395,209.90	$13.74
1904–5	158	20,456.35	277,402.40	13.56
1905–6	244	42,143.39	538,083.70	12.54
1906–7	157	20,387.02	303,255.60	14.80
	749	111,814.18	$1514,551.60	$13.54
Fiscal Year	Entries	Acres	Receipts	Average Price per Acre
1907–8	299	58,047.10	$647,584.55	$11.15
1908–9	182	26,590.68	502,743.65	18.90
1909–10	189	26,074.16	657,175.80	25.20
1910–11	83	15,284.89	251,323.03	16.44
1911–12	76	7,951.05	402,521.78	50.62
	829	133,947.88	$2461,348.81	$18.30

Now, these facts seem cunningly arranged to mislead, for though they are intended like those in Mr. Smith's letter to us, published Nov. 22, 1913, to prove that classified lands have been selling, it appears to include all

lands, some of which were not sold at classification prices at all, because they had not been withdrawn from classification before sale or had been filed on, before withdrawal. To show that such lands exist, we quote the report of the Commissioner of the General Land Office for the fiscal year ended June 30, 1907:

> In the case of coal lands withdrawn for classification and valuation, persons who had prior to withdrawal initiated valid possessory claims are permitted to perfect same, notwithstanding the withdrawal.

It is interesting to note the fact that the entries in 1907-1908 were 299, the acreage 58,047 acres, and the average price a trifle over $11 per acre, while in 1911-12 the entries were only 76 in number, the acreage only 7951 acres and the average price had risen to over $50. Do not all these facts tend to show that in the first of these years, several plots were sold at the minimum under the law of 1873?

It is interesting to note in the report of the Geological Survey for the fiscal year ended June 30, 1912, out of 829, no less than 628 entries were for $10 or $20, the exact amounts named in the act of March 3, 1873, leaving only 201 entries sold at other prices, mostly higher than $20 but nineteen lower than that figure. Of course, the Geological Survey has chosen the two prices, $10 and $20, for some inferior lands, but doubtless most were not sold at the Survey's prices at all.

A well posted Westerner writes us:

> I confirm your conclusions that the sales in 1907-08 were largely on unclassified lands and where the lands had been filed upon, prior to withdrawal and valuation. These lands were sold, of course, at the minimum prices, although the Government, in some cases, contested these filings, asserting that the parties were not actually in possession. There is no doubt in the world that locators took advantage of their knowledge of the Government's intention to revalue and classify coal lands and therefore in 1906, on some unsurveyed land, upon which there were squatters under the law of 1873, giving a man the first right to purchase by paying the minimum price, this right was exercised by many people and filings made in the latter part of 1906 were paid for in 1907 at the minimum prices which, no doubt, swelled the acreage.

Mr. Ashley himself in a letter of Dec. 26, 1913, says:

> Of course, it is obvious that all prices except $10 and $20 are those fixed by the Geological Survey. Since the greater part of the coal lands classified within the past six years have been valued at the minimum of $10 and $20 it is probable that a large proportion of the tracts listed as sold at those prices are of such character as have been or would have been if classified, when sold, appraised at those prices.

This opinion we cannot indorse and we only quote the statement to evidence that coal lands have passed at unclassified figures.

As a further reason for our belief, that coal is not selling freely, we quote from the report of the Secretary of the Interior to the President, Dec. 10, 1913:

> Our coal land is not being used under this plan (the classification of land and its vending at the price appraised) save under exceptional conditions of local and immediate demands and the purchaser, where there is one, is speculating on the best guess that an honest geologist can make as to the amount of coal in the ground.

So far we have said nothing about the fact that the prices for coal land were, when first appraised, more reasonable than they now are. Despite the fact that the government withdrew first, those plots which were most valuable, the appraisements given in the report of the Commissioner of the General Land Office for the fiscal year ending June 30, 1907, show the following figures: Non-coal, 1,269,720 acres; land to be sold at legal minimum, 24,950,120 acres; $20 per acre, 94,400; $25 per acre, 212,200; $30 per acre, 8000; $40 per acre, 2720, and $50 per acre, 85,880. These prices, it will be seen, are well below $510 per acre, which is now the maximum.

It is true higher prices were then in contemplation for the Commissioner says in the same report, "A considerable amount is being scheduled as coal lands of great value ranging as high as $75 per acre." Confiding commissioner, how could he gage the avarice of the land-holding class, be it bond holder or bureaucracy!

There is another line of misrepresentation which consists in urging that sales are as satisfactory now as they were before prices of coal land were raised. The Survey urges that increases in price have not retarded sales. We have seen how evident it appears that the figures showing sales at higher prices are not really representative of true conditions. They probably include all three types of abnormal transfers: Sales not made at present ratings, sales made at lower prices than now rule and sales of coal land made for their value as town sites.

But even if we assume that the sales since June 30, 1907, show all that is alleged, we cannot see that the Geological Survey proves its case. Let us quote other enlightening utterances of the Commissioner of the Land Office, for he, like the Secretary of the Interior, inconsiderately at times lets the whole truth become manifest. He says in his report for the fiscal year ending June 30, 1907:

> The futility of the Land Act of Mar. 3, 1873, is shown in the fact that since its enactment less than 500,000 acres of coal lands have been patented under it, while millions of acres of coal lands have been taken under other forms of entry, some of it unwittingly, but large areas in order to avoid the terms of the coal-land act, coal lands being the highest priced lands offered by this government.

So there *was* a marked tendency to obtain coal lands before 1907, but people believed that the evasion of the law provided a better way and the sales were not made of such lands under their proper title, but as if their real value was for farming purposes. It is true this was a mistake; the Land Office has been rounding up offenders and making them pay the larger prices. But we are not concerned with the error in judgment, but with its effect on sales, and as the Commissioner shows, it restricted these most measurably. Perhaps in many cases this also accounts for recent sales, for when developments have been made it is better to pay well for the land than to throw improvements away.

All in all, the report made year after year to the President is misleading in the extreme. The public have been deluded. The high cost of living is being raised in the West by the restriction of competition in that section. It is generally acknowledged that prices of coal at the mine in the public-land states are higher than in the East. Let us quote the Commissioner of the General Land Office in his report of June 30, 1910:

> The progress of advancement in the West is being retarded under present conditions by the difficulty in the successful operation of new mines under legislation as it exists today. Competition has been checked. The consumer is having to pay therefore, a greater price than it would be reasonable to expect he would have to pay if it were possible to open mines under legislation which would encourage the development of mines.

Therefore, it is with hope that we hail F. K. Lane's report, and the statement of G. O. Smith before the American Mining Congress. It is none too soon that a new system should be inaugurated. We are thoroughly in accord with the Geological Survey in believing that the royalty system is by far to be preferred to one based on outright sale.

Legal Department

When Is a Coalyard a Nuisance?

By A. L. H. Street*

SYNOPSIS—Location or manner of operation will not be interfered with unless it constitutes an unreasonable interference with residential rights.—Nature of neighborhood a controlling circumstance.—Amount of investment no defense.—What American and Canadian courts have held.

A coal yard, being a part of a lawful business, is held by the courts to become an abatable nuisance only when it is so located or so conducted as to become obnoxious to the general run of citizens.

The Alabama Supreme Court has sustained the right of an owner of property in a residence district to maintain a suit to enjoin the maintenance of a yard and coal bins so near his dwelling-house as to render habitation thereof undesirable, unpleasant and burdensome, on account of the emission into the air of coal dust. (Johnson vs. First Avenue Coal & Lumber Co., 54 Southern Reporter 598.)

It is true, however, that the complaint in this case was coupled with a protest against the operation of a planing mill in connection with the coal business, which increased plaintiff's discomfort, because of the noise and vibration produced by the mill. But the decision of the court recognizes the emission of coal dust as constituting a nuisance independently of the planing mill. The court sustained the right of the legislature to define abatable nuisances, in the proper exercise of the state's police power to protect the public health and safety; but, on the other hand, upholds the right of owners of coal yards to be protected in the enjoyment of their property, under the guaranty of the Federal constitution that no person shall be deprived of his liberty or property, unreasonably, arbitrarily or without due process of law. This constitutional right, the court says, "cannot be destroyed under the guise of police regulations. The legislature cannot, therefore, by its mere *ipse dixit,* make that a nuisance which is not in fact a nuisance or akin thereto."

The principle that a private citizen cannot maintain a suit in his own name, as distinguished from an action brought by public authorities, to enjoin continuance of a claimed nuisance, unless he suffers loss or inconvenience different in kind and degree from that suffered by the public at large, was applied in this case. The court holds that an individual must show the existence of a continuing nuisance or a real danger of serious and irreparable damage. "In determining whether an alleged nuisance should be abated, everything should be looked at from a reasonable point of view. The law does not regard trifles or very small inconveniences, but only those that are sensibly so—those which diminish the comfort or enjoyment of the complainants, or those sought to be relieved, or which sensibly diminish the value of property sought to be relieved, from the effects of such alleged nuisance.

*Attorney-at-law, St. Paul, Minn.

An Individual Must Expect to Suffer Some Annoyance

If one lives in a town, of necessity he must suffer some annoyance from the carrying on of the various trades which are properly located and carried on in his immediate vicinity, and which are necessary for the public trade and convenience, and for the public at large." And, according to the same decision, if a person takes up his residence in a business district, he must abide the natural inconvenience attendant upon residence in such a neighborhood. But if a business enterprise invades a residence district, a dwellinghouse owner will be entitled to enjoin conduct of the business in such manner as impairs the enjoyment of his home and the value of his property.

But, as decided by the Illinois Supreme Court in the case of Wente vs. Commonwealth Fuel Co., 83 Northeastern Reporter 1049, the standard of discomfort in the enjoyment of a home is not established by the sentiments of "persons of delicate sensibilities and fastidious habits, but by the habits and feelings of ordinary people."

In the last cited case, which was a suit to restrain defendant from piling coal against the wall of plaintiff's building and from operating a coal hopper in such a manner as to cause smoke, dust and cinders to permeate the air in the building, the Illinois court decided that the fuel company could not assert as a defense to the suit the fact that the hopper had been created at great expense. Justice Cartwright said: "If the existence of a private right and the violation of it are clear, it is no defense to show that a party has been to great expense in preparing to violate the right. The law does not undertake to estimate the difference between the loss that would be sustained by the party owning the thing complained of and of the damage to the injured party, nor to grant or withhold relief on such a basis."

Judge Refused to Grant Temporary Injunction

In a New York case, Russell vs. Popham, 3 New York Legal Observer 272, a judge refused to grant a temporary injunction (a restraint pending determination of the right to a perpetual injunction) against the operation of a coal yard adjacent to plaintiff's dwelling-house. He said: "A coal yard *prima facie,* is not a public nuisance, though it is possible so to use it as to make it noxious to the public. But if the affidavits on the part of the defendant are true, this yard is not so conducted as to be a public nuisance. The alleged injury to the complainant's house by the deposit of coal upon the adjoining lot may be such a private nuisance as to entitle the complainant to the interference of this court, after he has established the fact that it is a real and substantial and continuing injury to his premises, in a suit at law. It would, however, be going much further than the court has heretofore considered itself as justified in going, to interfere by a preliminary injunction upon the state of facts presented."

Recent Developments in the Colorado Strike

At the beginning of December of last year, inquiry was being made into the Colorado strike by both a federal grand jury in Pueblo, and a military commission at Trinidad. Before the former, indictments were brought against John P. White, president of the United Mine Workers of America, Frank J. Hayes, vice-president, and others, in all 25 persons. The jury returned 25 indictments against 24 men, Hayes being charged with obtaining a monopoly on labor and conspiring to restrain trade. The specific charges against those indicted include the stopping of coal destined for interstate purposes, the holding of cars after they were loaded for shipment and the asking of Wyoming operators to withhold coal from Colorado.

The military commission listened to the admission of Robert Uhlich, indicted president of the local union, that he had personally carried arms to the 400 miners at Ludlow, the night before the last battle at that place when a mine guard was killed by a shot. He was arrested and the authorities are seeking his deportation. Born in Saxony where he deserted the army, he fled to France, Spain and Mexico, and did not come to Colorado until 1910.

TWO BASES FOR SETTLEMENT REJECTED

On Dec. 2, the miners refused to accept the proposition of Governor E. M. Ammons for a settlement based on the following understanding: The law forbidding employers to interfere with the joining of unions by their employees or to discharge or coerce them on account of their affiliations was to be enforced. The employment of checkweighmen chosen and paid by the miners was to be allowed and the 8-hr. law was to be obeyed. The workers were to be free to buy their goods and to board where they pleased. The miners were to be paid twice a month. All provisions of the coal-mine inspection law were to be observed and all strikers were to be reinstated except where guilty of acts of violence.

A joint proposition of the governor and of the Secretary of Labor, W. B. Wilson, was that an arbitration committee should be formed consisting of three operators, three strikers and one disinterested party. All questions involved in the strike were to be submitted for adjustment except that of recognition of the union. This proposition was held up until the referendum vote accepting or rejecting the proposal of the governor had been cast.

When, on Dec. 4, the count of the referendum vote revealed a determination on the part of the miners to reject the original proposition, W. B. Wilson met with the operators and endeavored to get them to submit the difference to arbitration, but they refused. So he returned to Washington.

OPERATORS REDUCE PRICE OF COAL

On Dec. 3, the operators declared that the miners were working so steadily that a drop of $1.75 per ton could be made in the price of lignite. It had been $6.50 retail for first grade and $6 for second grade in Denver, for some weeks.

Vice-President Hayes, of the Mine Workers Union, then issued a manifesto stating that the coal offered for sale had been standing since before the strike and that the operators had been trying to make an excess profit of $52,000 per day on it for two months.

On the same day Dec. 3, President J. McLennan and Secretary W. T. Hickey, of the State Federation of Labor, called a convention to meet Dec. 16 to consider a statewide sympathy strike and Dec. 5, nine speakers were sent out to urge such a strike on the labor unions. The miners of the Aguilar district resolved on Dec. 3 to request the district officers to take the necessary steps for the recall of Governor Ammons and General Chase, the latter being at the head of the state militia.

THE MILITARY COMMISSION

On Dec. 6, the military commission reported on 43 cases arising out of the strike. It recommended that five men be held for murder, three for felonious assault, two that their cases may be further investigated and Uhlich as a dangerous agitator and alien.

The commission then took up its investigations at Walsenburg and dismissed 20 men. On Dec. 12, Captain Colesworth was named to relieve Major C. E. Townsend as acting judge advocate with Major Boughton. This was a cause of great rejoicing to the union officials. They alleged that the militia in Major Townsend's district took Andrew Colnar, an innocent Pole, and caused him to dig his own grave on the threat that he would be shot in the morning and taunted him until he fainted and fell in the hole. Further they stated that union officials have been held incommunicado and without charges being made.

The National Socialist party in Chicago and the Young Women's Christian Association sent word to the miners' union, the word arriving on Dec. 13, that they would send money for the support of the children of strikers.

On Dec. 16, Adjutant General John Chase declared that the mines were getting their full quota of men, the Forbes mine, for instance, being about 5 per cent. short and the Ideal having a full quota. The men were leaving the tent villages ostensibly for other states, but many of them sought work in nearby towns as strike breakers. He stated that in accord with the law, all men entering Colorado to seek employment were warned that a strike was in progress.

THE STATE FEDERATION MEETING

The much heralded meeting of Dec. 16, at last convened, but no figures of national importance in other lines than coal mining were in attendance. There were, however, the familiar figures of J. P. White, president, and W. Green, secretary of the United Mine Workers of America, and "Mother" Jones. In all about 450 delegates represented 250 unions. W. Green delivered the following remarks according to the "Rocky Mountain News":

There was a time when the governor could have rendered a distinct service to the people of the state, but that time has long passed. He should have given the operators one week to arbitrate with the understanding that, if they did not do so, he would instruct the attorney-general to go to court, have a receiver appointed for the coal companies and operate the mines in the name of the state.

It does not appear that Mr. Green's remarks were taken seriously, as his wild suggestions, which are neither just nor of legal force, were not embodied in the resolutions adopted. A visit was made by a committee of five on Governor E. M. Ammons. The committee declared that if the military commission executed anyone, lynching parties would follow.

THE STATE-WIDE STRIKE UNPOPULAR

The federation did not vote for a general strike in Colorado as the delegates thought that Wyoming coal miners should first strike in sympathy. Nevertheless a resolution was passed in a half-hearted way empowering the executive committee of the Colorado Federation of Labor to call a state-wide strike without further formality or notice. This meant but little as the federation officials had the power to make such a call without any such vote.

The meeting supported the resolution of Congressman Edward Keating in favor of a congressional investigation into the Colorado strike, and ordered its approval of the resolution sent to all the Colorado congressmen; it indorsed the single tax, commended Roady Kenehan, the state treasurer demanded the removal of Sheriff J. Farr, of Huerfano County, and condemned the newspaper inquiry into the strike, declaring it representative of only a few papers and stating that the miners were not allowed to talk as long as the operators. It also made the accusation that the judgment was prepared before the testimony was heard. It recommended a constitutional amendment providing for the operating of coal mines by the state and favored the bill permitting cities to file upon federal coal lands for municipal use.

On Dec. 18, the federation ended its sessions, having first arranged to prepare petitions for the recall of Governor E. M. Ammons and having marched to the state house and met the governor and Attorney General Fred Farrar in the house of representatives. The governor agreed to investigate charges brought against the militia and desired the federation to name a committee to assist in the investigation.

On the same day 185 strike breakers were brought into Trinidad from Pennsylvania. About 1500 strikers and sympathizers with the strike met them and were kept back only with difficulty by five companies of militia. On Dec. 19, fighting took place at Oak Creek, Colo., and at the Cameron mine, Walsenburg, Colo., which has been running steadily since the strike commenced.

THE PROGRESSIVE PARTY AND THE STRIKE

On Dec. 22, Merle Vincent, leader of the Progressives on the Western slope, demanded that Governor Ammons send a communication to operators and miners requiring them to recognize and negotiate with each other. Failing results, he should call a special session of the legislature to devise ways and means for operating such mines as are on state lands. Vincent declared the militia, "the body-servants to the operators" and added that the operators could be sued for having organized in restraint of trade.

Four of the five committeemen appointed by the strikers to prepare charges against the militia met on the same day. They were Prof. J. H. Brewster, of the University of Colorado. James Kirwan, of the Western Federation of Miners, Eli M. Gross, of the Denver Cigar Makers Union, and John R. Lawson, of the striking miners. Lawson was elected chairman and Gross, secretary.

Discussion By Readers

The Certificate Law

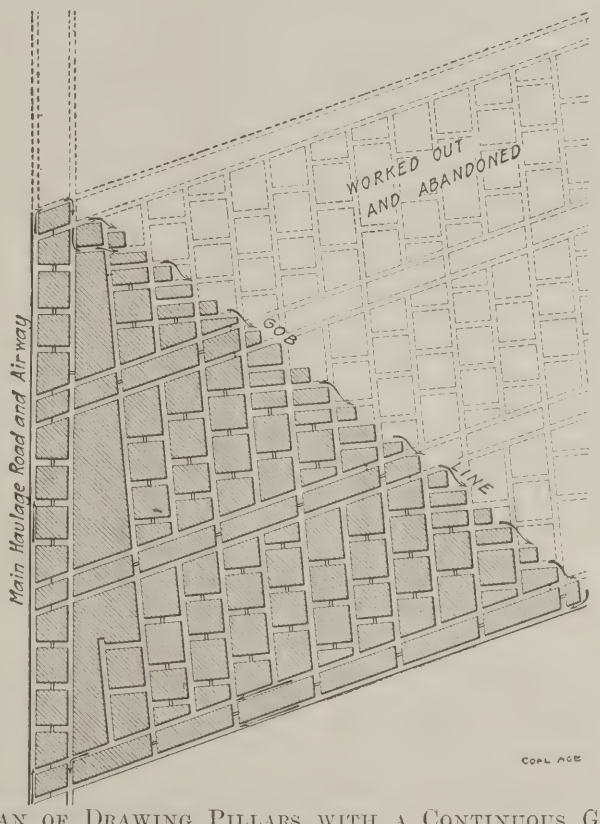
Letter No. 9—In recent issues of COAL AGE, I have read the opinions of different men as to the advisability of establishing an interchange of certificates, issued by the different mining departments and mining boards in the several coal-producing states of the United States. I am in favor of a law or plan that would bring about an interchange of certificates for such positions as mine managers (mine foremen) mine examiners (firebosses) and hoisting engineers; because of certain cases that have come under my observation, in connection with my work as chief clerk and secretary of the State Mining Board.

Men have made application in Illinois for examination as mine managers, and have had in their possession certificates of competency granted them in other states. These certificates may have been issued several years before, since which time they have acted in the same capacity successfully, for a number of years; but, under the state mining law, they were required to take an examination in practically the same subjects in which they had formerly been examined in another state. Their work had taken up so much of their time that they had not kept up their study and were unable to pass the examination in Illinois. Nevertheless, they were capable and qualified according to the laws of another state to perform such duties and had secured a certificate of competency as required by law.

In most of the states that produce coal, there is created by law, a board or commission or a chief mine inspector, who have charge of the examinations for certificates as mine managers, etc., and the law, in most cases, provides in what subjects the applicant shall be examined. The conditions are very similar. Why then should a man who has passed the examination in one state, and received a mine manager's certificate, be asked to take an examination in the same subjects in another state?

In my opinion, there should be an interchange of certificates, with the possible exception of state mine inspector.

MARTIN BOLT,
Chief Clerk, State Mining Board.



Springfield, Ill.

Extraction of Pillars

I have been greatly interested in the recent discussion bearing on the recovery of pillar coal and submit herewith a plan that has proved very successful in this locality, both with respect to the percentage of coal recovered, the ventilation of the pillar workings and the general condition of safety while drawing back the pillars. The system also favors a minimum cost of production.

As shown in the accompanying sketch, cross-headings are driven off the main haulage road in pairs. These headings are driven on 50-ft. centers and about 300 ft. apart. Rooms are turned to the rise of the cross-headings, the rooms being driven on 80-ft. centers and bear to the left or toward the main headings, about 10 ft. per 100 ft. of length. The grade in the rooms is about 2 per cent.

In this system, the main headings are driven to the boundary line or the limit of the panel, and the work of drawing back the pillars is started at the top rib, on the inby end of the last pair of cross-headings, or the extreme inby end of the panel. Some considerable time is required to develop the full extent of the gob line in a panel or section. As shown in the figure, about seven ribs are all that can be maintained between two pairs of cross-headings. It is important that the development of the gob line should not be rushed too rapidly, but this development should take place regularly, or serious results may follow. Thus, each pillar is stepped back from 35 to 40 ft. before work on the next pillar is started.

PLAN OF DRAWING PILLARS WITH A CONTINUOUS GOB LINE

The method is as follows: The pillar is cut across so as to leave about a 15-ft. stump. When this has been done, a slab of about 4 ft. is taken off on the inby rib. Owing to the angle by which the rooms bear toward the main heading (1 to 10) the cross-cut in the pillar gains about 8 ft. toward the "flat" or cross-heading. On this account, it is clear that the steps in each successive pillar cannot be less than 35 or 40 ft., or much coal would be lost in the stump end when working back.

The ventilation is on the ascensional plan, the air being taken in on the main heading to the inby end and returned along the gob line, as shown in the figure. This is ac-

complished by putting canvas checks in the rooms. By means of canvas hung on the rise-headings, some air is diverted through the crosscuts along the gob line, sufficient to keep these places free from gas. The circulation is so arranged, however, that the most of the air is made to traverse the gob line.

While this is a gassy mine, we have never been troubled with gas on the falls, which proves the efficiency of the system. We always expect to find traces of gas on the top rib, but this is so diluted by the air below the point of ignition that it can only be found by a careful test.

Handling Fine Dust in Washing Coal

In the article of J. Drummond Paton on this subject, COAL AGE, Oct. 18, p. 573, the statement is made that "to allow all the small coal under 1 mm. (one-twenty-fifth in.) to pass into the washery is radically wrong." The author further states that the formation of sludge when this and finer dust are allowed to pass into the washery makes the operation of the latter difficult. He explains that not only is the washed fine coal hard to dry but the mass is so dense that the passage of water through it is slow; and, besides, the fine sludge absorbs an immense quantity of water. He concludes that this fine dust cannot be treated successfully in a washer.

The experience of the Keystone Coal & Coke Co., in their washeries at Salem and Huron, would seem to prove the contrary of this claim. These washeries generally get only the sizes of coal that pass through the one and one-fourth-in. bar-screen. But since this coal is mostly cut by machines, it contains considerable fine dust that is high in both sulphur and ash. This condition, therefore, presents such a problem as Mr. Paton claims cannot be handled successfully by washing. I want to say that the rejections at these washeries show a low percentage of coal, not exceeding 5 per cent., while the washed coal shows a satisfactory reduction in ash and sulphur. No water is thrown away, except that which is carried up with the washed coal and refuse and that which is drained out of the tanks once a week for the purpose of inspecting the submerged parts of the machinery.

Before draining the tank, the machinery is always run slowly for a considerable time, in order to save the fine material. That this fine material has undergone an effective separation is proved by repeated analyses, which have usually revealed the following results: Washed coal smudge, sulphur, 1.3 per cent.; ash, 14 per cent. Refuse smudge, sulphur, 5.18 per cent.; ash, 29.5 per cent.

The washed coal smudge here referred to is under one-seventieth in. in diameter and is allowed to pass off from the washed-coal elevator boot along with the overflow water.

A series of tests of the washed coal have shown that sizes down to one-fortieth in. in diameter contain about the same precentage of impurities. Only as the size approaches one one-hundredth in. in diameter, does the material show any great increase in sulphur or ash. For this reason, we aim to draw off only the very finest of the smudge, the rest being good enough to pass up with the washed coal. The fine smudge is not wasted, but is finally allowed to settle out and mixed with the other middlings for the plant boiler fuel.

We have never yet determined here just what proportion of the one-seventieth-in. material passes up with the washed coal. The proportion, however, is probably small, since the greater part of it overflows with the water. Particular attention has been paid to the arrangement of the sluices and settling tanks. The final settling tank, into which all waters flow before returning to the circulating pump, is arranged so that the least possible disturbance of the water occurs. The scrapings from this tank are a mixture of settlings from both refuse-tank water and washed-coal-tank water; and, as previously stated, this goes to the boiler plant. Its analysis is approximately as follows: Sulphur, 2.7 per cent.; ash, 16 per cent.

Our experience leads me to conclude that the dry dust, in the separation suggested by Mr. Paton, could not be handled as easily and economically, in our case, at least, as the smudge we are handling at the present time; and it is certainly being washed fairly successfully, as is proved by the analyses.

Grand Jury Investigates Strike Situation

Referring to the editorial, Two Phases of the Colorado Strike, COAL AGE, Dec. 20, p. 943, allow me to draw attention to the following rulings of the federal grand jury, bearing on the strike situation.

The federal grand jury investigating the coal strike in Colorado recently issued a statement relative to conditions in the mines in which it says: "The operators appear to have been somewhat remiss in endeavoring to secure and hold the good will of their employees, and the grand jury has deduced from testimony that there existed reasonable grounds for many of the grievances complained of by the miners. We believe that many of these complaints are substantiated and have merit."

The grand jury found that the state laws have not been so enforced as to give all persons concerned the benefits which are derived therefrom, and that "the coal companies have been sufficiently influential to nominate, elect and control many county officers, and have done so with the result of complicating the industrial situation by excusing political prejudices."

The report further sets out that "many camp marshals whose appointments and salaries are controlled by coal companies have exercised a system of espionage and have resorted to arbitrary powers of police control, acting in capacity of judge and jury and passing sentence upon miners who had incurred the enmity of the superintendent or pit boss for having complained of real grievances or for other causes. These, taken with assaults by camp marshals upon miners, have produced general dissatisfaction among miners, who fear generally to complain of real grievances because of danger of their discharge."

Viewed in the light of these grand-jury investigations, the present labor trouble in Colorado does not appear to have all the right and justice on the side of the mine owners.

A CONSTANT READER.

How To Buy Coal

Letter No. 1—I have read with considerable interest the article by J. S. Burrows, entitled, How to Buy Coal, COAL AGE, Dec. 6, p. 866. While Mr. Burrows has demolished, by very logical arguments, the preconceived ideas of a large number of purchasers of coal, and even admits that he was one of the originators of the heat-unit system, he, nevertheless, offers no substitute.

I quite realize that in the chemical analyses, by sample, of several hundred tons of coal, the result is more or less subject to error; but, if the net result of a series of samples of different lots is taken, say an average of ten separate analyses, would not the result be as much to the advantage of the seller as the buyer. While the sample of one or two lots might show an excessive proportion of ash, sulphur, or a low-heat value, it cannot be denied that subsequent analyses might give the advantage to the seller. An average, therefore, of, say ten analyses of samples, taken from as many distinct deliveries of approximately equal quantities of coal, would at least give a fairly good general idea of how the coal was running, and whether or not the seller was living up to the standard required by the contract.

The purchase of coal for bunker purposes differs materially from that for shore use; and, aside from the effort to obtain suitable coal for steaming, careful consideration should be given to the elimination of any risk of spontaneous combustion, especially where the vessel is to be bunkered for a long voyage during which the coal will be subjected to climatic changes. In such cases, it is very difficult to arrive at a practical result, owing to the difference in steamers, engineers, firemen, weather conditions, etc.

Until some better and more reliable method is established, therefore, it is fair to assume that the purchaser is safeguarded, at least to some extent, against a poorer grade of coal than is guaranteed by the seller, and the latter will suffer no hardship by the present system provided that he intends to live up to the conditions of his contract.

In the case of bunkering steamers, it seems to me that a fair way of sampling is to take a small sample of coal from each or every other bucket, keeping the samples taken from each barge separate; and after thoroughly mixing each lot reduce the amount in the customary manner to a quantity sufficiently small to analyze. I believe this would give a net result that would demonstrate, with a degree of fairness, the quality of the coal delivered.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

RATIO AND PROPORTION

Ratio—The word "ratio," as used in mathematics, expresses the numerical relation that one quantity bears to another of the same kind. The two quantities so related or compared are called the "terms" of the ratio; and the two terms taken together are called a "couplet."

How Expressed—A ratio is expressed in two ways:

1. By writing the two terms with a colon between them; thus, the ratio of 2 to 4 may be written 2:4 and is read 2 is to 4.

2. By writing the terms as a fraction; thus, the ratio 2:4 may also be written 4/2, the first term of the ratio being preferably made the denominator and the second term the numerator of the fraction.

When so written the ratio may be read as before "2 is to 4"; or, as is frequently done, "4 divided by 2," which expresses the fact the ratio is intended to convey; namely, that the first term of the couplet 2:4 is a base or standard of measurement for the second term, and the ratio shows how many times the second term will contain the first, or expresses the value of the second in terms of the first or standard.

The Meaning of Ratio—To illustrate the meaning and use of ratios, in mining problems:

Nitrogen gas is 14 times as heavy as the same volume of hydrogen, and the ratio of the weights of equal volumes of these two gases is therefore 1:14. In this case, hydrogen is made the base or standard of measurement.

Again, a cubic foot of anthracite (hard coal) is, practically, 1½ times as heavy as a cubic foot of water, and the ratio of the weight of anthracite to that of water, volume for volume, is therefore 1:1.5. Here, water is the standard and the weight of the coal is calculated from the known weight of the standard.

Ratios are useful in the calculation of many problems in mine ventilation, where it is often desired to calculate the volume of air a given power will circulate in one airway of a certain size, from the circulation produced in another airway of known size, which is taken as the standard.

A Simple Ratio—A simple ratio is one formed of a single couplet of like terms only; as when length is compared with length, or width with width.

Example—If one strip of carpet contains 10 sq.yd., how many square yards are there in another strip of the same width but twice as long?

Solution—These strips of carpet differ only in length, the length ratio being 1:2; or 2/1 = 2. Hence, the number of square yards in the second strip is found by multiplying the number of yards in the first strip by this ratio. Thus, 10 × 2 = 20 sq.yd.

In this case the ratio is a simple ratio, because it is expressed by a single couplet the terms of which both refer to the length of carpet in the strips. This is possible, because the width of the strip is the same in each case and need not therefore be considered.

The Coal Age Pocket Book

A Compound Ratio—A compound ratio is one formed of two or more couplets, the terms of which are different for each couplet. In other words, a compound ratio involves two or more simple ratios of different kind.

The value of a compound ratio is determined by multiplying together the first terms of the several couplets, for a new first term; and, likewise, the second terms of those couplets, for a new second term. The resulting ratio is the value of the compound ratio.

Example—If a certain strip of carpet contains 12 sq.yd., how many square yards will there be in another strip twice as wide and three times as long?

Solution—In this case, two simple ratios are involved. The width ratio is 1:2, and the length ratio 1:3, which together form a compound ratio that may be expressed by the products of the corresponding terms. Thus,

$$(1 \times 1) : (2 \times 3); \textit{ or simply } 1 : 6$$

The number of square yards in the second strip of carpet is, then, 12 × 6 = 72 sq.yd.

Example—A certain mine sump, 6 ft. wide, 14 ft. long and 11 ft. deep, holds when full 6912 gal. of water; what is the capacity of another sump that measures 7 ft. in width, 12 ft. in length and 6 ft. in depth?

Solution—These sumps differ in all three dimensions, width, length and depth. The width ratio is 6:7; the length ratio 14:12; and the depth ratio 11:6. The compound ratio of capacity, is therefore, in this case,

$$(6 \times 14 \times 11) : (7 \times 12 \times 6); \textit{ or } 924 : 504$$

This ratio can be reduced by dividing both terms by 84, which is their greatest common divisor; or by canceling the common factors in the two terms of the compound ratio; thus,

$$(\overset{2}{\cancel{6}} \times \overset{}{\cancel{14}} \times 11) : (7 \times \overset{6}{\cancel{12}} \times \cancel{6}) = 11 : 6; \textit{ or } \tfrac{6}{11}$$

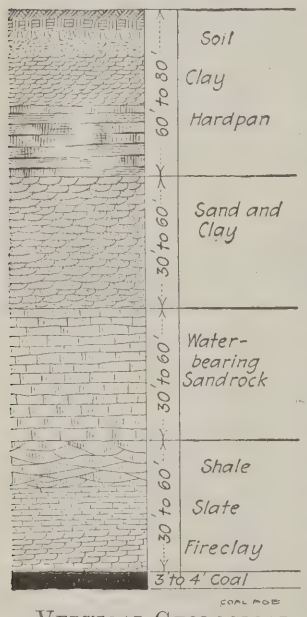
The capacity of the second sump or basin is, then,

$$6912 \times \frac{6}{11} = 3770+ \textit{ gal.}$$

To Reduce a Ratio—To simplify the working of problems all ratios should be reduced to their simplest form, by writing the ratio as a fraction and reducing this fraction to its lowest terms.

For example, the ratio 12:16 when reduced to its simplest form is

$$\frac{16}{12} = \frac{4}{3}; \textit{ or } 3 : 4$$



The terms of any compound ratio consist, each, of the corresponding terms of the simple ratios of which it is formed. These simple terms enter the compound ratio as factors or "elements," as they are called. In reducing a compound ratio, cancel the equal elements and factors in each term.

Inquiries of General Interest

Working Coal under Watery Strata

We are starting to develop a coal property that presents an interesting and difficult problem in mining. Having noted the previous valuable discussion on working coal under sandstone cover, allow me to present the following proposition for the discussion of readers:

We have already sunk an air shaft to the coal, which lies about 200 ft. below the surface. The shaft is making 500 gal. of water per minute, which all comes practically from the water-bearing sandrock, so marked in the accompanying section. This sandstone is not stratified and the water flows through it freely in every direction.

VERTICAL GEOLOGICAL SECTION

In order to assist in sinking the air shaft mentioned, we drilled two 10-in. boreholes, one on each side of the shaft and about 50 ft. distant from the same. We pumped about 150 gal. of water per minute from each of these holes; and the sinking of the shaft did not seem to affect the flow in either hole, even after the shaft had penetrated and passed through the sandrock from which the water came. The natural head of the water is about 100 ft. above the sandrock, which extends for miles in all directions from the shaft. The source of the water is unknown, there being no large bodies of water closer than 15 miles. I would like to suggest the following questions for discussion by readers:

1. If the coal in this seam is taken out to such an extent as to break the sandrock, would it be reasonable to expect the same flow of water from each break as what finds its way into the shaft?

2. Assuming we can handle from 1000 to 1200 gal. of water per minute, in this mine, and estimating that it will be necessary to leave about 50 per cent. of the coal in place, in order to prevent breaking the rock, would it be advisable to leave such a large percentage of coal for the support of the overlying strata? Under ordinary mining conditions we would expect to take out from 80 to 85 per cent. of the coal.

3. We expect to sink a hoisting shaft about 300 ft. from the air shaft. Will this shaft make the same amount of water as the air shaft?

GEO. MACPHAIL, Engr.,
What Cheer Coal Mining Co.

Bay City, Mich.

[This is a problem of great interest in coal mining. Our correspondent has given little information in regard to the geological cross-section of the locality. The vertical section given, however, shows approximately the character of the strata overlying the coal seam, and it may be assumed that the location of the shaft is in the basin, at or near the bottom of the syncline. Here is an opportunity for practical mining men to give helpful suggestions, by citing instances in their own experience. Let us have a good discussion of the question.—ED.]

Weathering of Coal

Recently, I read a statement to the effect that a small pile of coal that had become heated to a temperature of 165 deg. F., later cooled down to the normal. As this is contrary to general experience in the practice of storing coal, I would like to ask if such a statement could be correct.

In the storage of coal, is the idea of ventilating the pile in order to reduce the heat generated, of practical value; or, in other words, can the idea be applied to advantage in the storage of coal in large heaps or in bunkers?

PURCHASING AGENT.

Philadelphia, Penn.

Opinion varies widely in regard to the immediate cause of the generation of heat in a coal pile. There are unquestionably a number of contributory causes, all of which produce a greater or less effect and assist or retard the generation of heat in the coal. One of the most potent of these causes, probably, is the absorption by the coal, of the oxygen of the air. The oxygen thus absorbed is brought into intimate contact with the carbon of the coal. The absorption of oxygen is greater in the small sizes of coal, owing to the greater surface exposed to the atmosphere, for the same mass concerned.

Moisture, the presence of sulphur in the coal, the hardness and cleavage character of the coal, are all factors that assist or retard the reaction that takes place between the carbon and the oxygen. This reaction generates heat, which in turn accelerates the oxidation of the coal.

The purpose of ventilating the pile would be to carry off the heat generated in this way. The idea, however, is not generally regarded as of practical application, not only for the reason that it is impracticable to ventilate a large coal pile or storage bin thoroughly throughout its mass: but the air introduced into the pile of heated coal furnishes the necessary oxygen to carry on the combustion.

Coal stored in bunkers should be kept as dry as possible and the space above and around the coal should be thoroughly ventilated. It is possible, although exceptional, for a coal pile that has started to heat, to cool down again under favorable climatic conditions respecting temperature and moisture in the air. Climatic conditions have a greater effect on the tendency of coal piles to heat than is generally supposed. This has been clearly shown by the difficulty experienced in seagoing vessels sailing in different climes.

Examination Questions

Miscellaneous Questions

(Answered by Request)

(*Concluded from last issue*)

(b) The introduction of a regulator in an airway has practically the same effect as increasing the length of the airway and will increase the water gage, for the same power on the air.

(c) For a constant power on the air, the pressure or water gage varies inversely as the quantity of air in circulation; in other words, the water-gage ratio is equal to the inverse quantity ratio. Calling the required water gage x and assuming an original water gage of 2 in.,

$$\frac{x}{2} = \frac{20{,}640}{12{,}250}$$

$$x = \frac{2 \times 20{,}640}{12{,}250} = 3.37 \text{ in.}$$

(d) For the same conditions in the airway and the same opening in the regulator, the power required to increase the circulation to the original amount, and the resulting water gage are determined by the rule that the power varies as the cube of the quantity and the water gage as the square of the quantity. In other words, the power ratio is equal to the cube of the quantity ratio, and the water-gage ratio is equal to the square of the quantity ratio. Calling the required power and water gage x, respectively, the original circulation being 6.5 hp. and a 2-in. water gage, we have

Horsepower, $$x = 6.5\left(\frac{20{,}640}{12{,}250}\right)^3 = 31.09 \text{ hp.}$$

Water gage, $$x = 2\left(\frac{20{,}640}{12{,}250}\right)^2 = 5.68 \text{ in.}$$

Ques.—If a true meridian line is established and the declination of the needle is known to be 4 deg. east of north, will the needle of a compass when unlocked read N 4° E?

Ans.—Assuming there is no local attraction to deflect the needle, it will point to the magnetic north when unlocked. If the sights of a simple compass having no declination plate be directed to the true north so that the sight line of the compass will correspond with the established true meridian, the reading of the needle will be N 4° E.

If, however, the compass has a declination plate and the declination of the needle is set off, 4 deg. to the east of north, the reading of the needle will then be zero; because, in setting off the declination on the compass, the zero of the limb or graduated circle has been moved 4 deg. to the right of the sight line of the compass. In this position, the north and south points of the graduated circle coincide with the magnetic meridian when the sight line of the compass is in the true meridian.

Ques.—If a given power produces 60,000 cu.ft. of air in three airways, each 6 ft. high, 8 ft. wide and 4000 ft. long; what quantity of air will the same *power* produce when one of these airways is closed?

Ans.—For the same power on the air, the quantity of air in circulation in a mine is directly proportional to the total sectional area of the airways or area of passage, and inversely proportional to the cube root of the rubbing surface. Assuming that each of the three airways, in this case, starts from the bottom of the downcast and returns to the foot of the upcast, making three separate splits of air, and ignoring the shaft or slope resistance, both the total sectional area and rubbing surface for the entire mine will be proportional to the number of airways or splits. This is true, since the airways are all of the same size and length.

Then, the quantity of air in circulation being proportional to the sectional area and inversely proportional to the cube root of the rubbing surface, the quantity ratio is equal to the area ratio times the cube root of the inverse rubbing-surface ratio; and, since there are 3 splits in the first case and 2 splits in the second, calling the required quantity of air x,

$$\frac{x}{60{,}000} = \frac{a_2}{a_1}\sqrt[3]{\frac{s_1}{s_2}} = \frac{2}{3}\sqrt[3]{\frac{3}{2}} = 0.7632$$

and

$$x = 60{,}000 \times 0.7632 = \text{say } 45{,}800 \text{ cu.ft. per min.}$$

The above method, by ratios, is the simplest, most direct and accurate method of calculating such problems.

Ques.—The depth of a downcast shaft is 600 ft. and the temperature 50 deg. F.; the depth of the upcast is 900 ft. and its temperature 100 deg. F. What water gage should result from this condition?

Ans.—Assuming the given downcast temperature (50 deg.) represents the temperature of the outside air, the height (h) of air column producing circulation in this mine, estimated in terms of the air in the upcast shaft, is

$$h = D\frac{T - t}{460 + t} = 900\frac{100 - 50}{460 + 50} = \frac{900 \times 50}{510} = 88.23 \text{ ft.}$$

The weight of 1 cu.ft. of the upcast air, at a temperature of 100 deg. F., assuming a barometric pressure B = 30 in., is

$$w = \frac{1.3273\,B}{460 + T} = \frac{1.3273 \times 30}{460 + 100} = \frac{39.819}{560} = 0.0711 \text{ lb.}$$

The pressure due to 88.23 ft. of air column of this air is then

$$p = w\,h = 0.0711 \times 88.23 = 6.28$$

The water gage corresponding to this pressure is

$$w.g. = 6.28 \div 5.2 = 1.2 \text{ in.}$$

Correction

(*Examination Questions, Nov. 8, p. 711*)

Ques.—The anemometer indicates a velocity, etc.

Ans.—The answer should read as follows:

(c) The water gage is 2.08 ÷ 5.2 = 0.4 in.

Coal and Coke News

Washington, D. C.

The Interstate Commerce Commission has handed down an unusually important decision in the case of the Traffic Bureau of Nashville vs. the Louisville & Nashville R.R. Co. In this it is found that conditions affecting the transportation of coal from Louisville & Nashville R.R. western Kentucky mines to Louisville, Memphis and Nashville are not so dissimilar as to preclude a comparison of rates from the same fields to these three cities. The rate of $1 per ton on coal to Nashville from Louisville & Nashville mines in western Kentucky is found to be unreasonable and a rate of 80c. is prescribed.

A like rate from Nashville, Chattanooga & St. Louis Ry. mines in Tennessee and Alabama is found to be unreasonable and a rate of 90c. is prescribed. It is held that the current complaints as to the unreasonableness of the rate of $1 to Nashville on coal from Illinois Central western Kentucky mines had not been sustained.

With reference to the question of refusal on the part of the Louisville & Nashville and Nashville, Chattanooga & St. Louis to switch coal to and from the Tennessee Central, as well as the practice of the latter in retaliating in kind is held to be unreasonable while the practice of the first two roads is said to be unjustly discriminatory. Finally it is held that a carrier may not exercise any arbitrary discretion in saying what roads and what traffic it will admit to its terminals and what shall be rejected.

The decision is of special interest because of the elaborate discussion it affords with reference to the use of statistics showing ton-, car- and train-mile movements as a basis for the making of rates. In this connection, speaking specially of coal movements the commission says in its decision:

Ton-mile statistics, reflecting as they do neither car loading, train tonnage, nor car- or train-mileage, are far from being infallible guides in fixing freight rates. A high average ton-mile revenue may be due to short hauls, a preponderance of which occasions the railroad traffic manager much uneasiness, while it has been repeatedly shown that traffic low in ton-mile earnings may, because of its farther carriage and greater density, be the most remunerative. Per-car earnings, with distance considered, are much more reliable.

Where the commodity moves in trainloads the earnings per train-mile furnish the best criterion, not only the car loading, but also such physical conditions as grades, etc., being here reflected. Comparisons of any kind, however, to be effective must be analogous, or nearly so; that is, the the rate charged or gross earnings derived on any basis for the transportation of a given commodity between two points furnishes a guide in arriving at the rate to be charged upon the same or nearly the same commodity between two other points similarly circumstanced.

Comparisons made with coal moving to the lakes for transshipment, to tidewater and between points in central freight association territory are of little value here because of the manifest difference in transportation conditions, particularly with respect to density of traffic, train tonnage, and return empty hauls.

Chattanooga, Knoxville and East St. Louis have coal mines in their immediate vicinities, and such juxtaposition of supply and market must needs exercise a material influence over the rates from farther distant mines thereby lessening the strength of the comparison.

In analyzing the actual tonnage situation, the commission points out that the $1 per ton rate to Nashville has been in effect since 1888 and has therefore remained unchanged for 25 years and that as the volume of traffic has greatly increased there is ample reason to believe that the proportionate share of revenue obtained from the hauling of coal in this way is much greater now than it was then so that a reduction is reasonably to be expected. No award is made of reparation for past charges.

The Rate Increase Controversy

An increasing number of coal producers are preparing to participate in the 5% rate advance controversy with the railroads and are filing statistics in opposition. The roads themselves are beginning to appreciate the character of the antagonism they must meet from this source and are getting ready to show statistically the situation under which they are laboring in coal territory.

Among the recent data filed by the roads are statistics showing that there has been an enormous increase in wages. According to this analysis the various railroad companies paid out $506,000,000 in wages and salaries in the year ending June 30, 1913 Estimates for 29 of the 38 railroad systems concerned show an increase in wages for 1913 over 1910 of $48,618,972.41, due to changes in rates of pay and working conditions.

This figure was obtained as a result of a request to the railroads to take the actual performance for the year ending June 30, 1913, and compare the rates of pay and working conditions prevailing in that period with those in effect in October, 1909, a period prior to the date of the important increases.

In addition to the increases up to June 30, 1913, careful estimates show that the increases in wages recently granted to the firemen, conductors and trainmen will add not less than $8,750,000 more to the expenses of the railroad, this estimate being based on the volume of business for the calendar year 1912.

In addition to the wage increases granted in the calendar year 1910, a small portion of which was effective in the fiscal year ending June 30, 1910, the engineers, firemen, conductors and trainmen have been awarded increases through arbitration proceedings amounting to $10,350,000 per annum on the eastern railroads, and increases in rates of pay have been granted to various other classes of labor amounting to large sums in the aggregate in addition to those granted in the year 1910.

Taken altogether, there has been an increase of 10.62 per cent. in the average rates of pay on these railroads in 1913 over 1910. Special data are also being prepared with reference to wage conditions in the coal regions.

Experiment Stations Are Popular

More bills for the establishment of mining experiment stations have been introduced within the past few days, one by Mr. Taylor, of Colorado, who calls for 10 such stations with elaborate functions, another by Mr. Hensley, who would create one such station at Flat River, Francois County, Mo. There seems to be little reason to expect that any action will be had on these proposals for experiment stations any more than on the numerous propositions of the same kind that have come to the front in past years.

HARRISBURG, PENN.

The Auditor General has made his first ruling under the new law taxing anthracite coal, effective the first of the year. It relieves operators of the payment of the tax on as much coal as is necessarily and exclusively used in the operation of their collieries.

This ruling provides that as much of the mined product as is burned for lighting or heating the mines or connected offices, or in providing steam or electric power to run fans or other machinery used in coal operating is to be tax free.

The Auditor General, however, draws a sharp line between coal used for such purposes and coal used at the collieries for the production of light, heat or power for other purposes. Some companies supply light to the dwellings they own, and in such instances and in cases where light, heat or power is sold, the coal will be taxed.

A rather curious question, of interest in many communities in the Anthracite country, has been put up to General Powell by county officials who ask whether coal pumped from river beds, where it has been deposited by floods, is subject to the tax. While the point has not been formally ruled upon, the department is of the opinion that such coal is taxable.

Lively interest in the new tax is being shown by officials of the anthracite counties for the reason that it is expected to make important additions to the revenues of their cities, boroughs and townships. Half of the tax collected will be retained by the state.

Rules Will Likely Be Issued Soon

While the Chief of the Department of Mines, Jas. E. Rodenck, has made no official announcement it is generally expected that rules promulgated at the recent conference of mine inspectors held in Reading will shortly be issued.

Among the rules is one which provides that coal companies in the anthracite fields employ patrolmen, whose duties it will be to make an inspection of the face of pitching breasts, at least once a day. The idea is to promote safety and to have first-hand assurance that no pockets of gas have escaped nor that there is danger of squeezing or of falling roof. This will probably mean the employment of at least

a half dozen patrolmen at each individual colliery. None but practical and long experienced miners can be given the position.

Another order will force the elimination of fuses and caps in blasting. Electric batteries must be used and the miner and his laborer must descend the breast and be present at the starting of the battery.

PENNSYLVANIA

Anthracite

Larksville—Employees of the Lance No. 11 Colliery of the Lehigh & Wilkes-Barre Coal Co., who have been on strike for two weeks, have gone back to work, pending a settlement of their grievance. Until the matter is heard and settled by the Conciliation Board, District Vice-President Yannis will act as check weighman, in place of Joseph Bogden, the discharged check-docking boss, who will still be paid by the men until the matter is settled.

Moconaqua—Mine workers throughout the anthracite field are interested in a question raised by the miners employed at the West End Coal Co.'s mine a Moconaqua, who ask that surveyors be required to join the union. It is the contention of some of the district officers that such a course is not legal, and a report on the situation is to be made at the next district meeting.

Lansford—Three collieries of the Lehigh Coal & Navigation Co., in Panther Creek Valley, are idle owing to a strike involving 2000 employees. At collieries Nos. 5 and 6 the drivers were requested to report 20 minutes before the regular starting time so that their mules would be harnessed in time. This they refused to do, and all the other employees went out on strike with them.

Scranton—The Delaware, Lackawanna & Western R.R. tracks which run from the Keyser Valley yards to the Pyne breaker in Taylor borough subsided recently from a mine cave, so that traffic was interfered with for some time. Extreme precautions are constantly taken to guard against disturbance of the main line, and it is not likely that such an occurrence will take place.

Bituminous

Harwick—The fanhouse of the Allegheny Coal Co.'s mine here was wrecked by an explosion of dynamite Christmas night. Three men whose names appear on the commitments as John Doe, Richard Roe and John Dinamiter have been arrested. They were traced to "Dinamiter's" home by footprints in the snow, which led from the scene of the explosion. Guards have been kept at this mine since Oct. 8, when a riot occurred, but these were eluded by the miscreants in the darkness. Despite the dynamiting of the fan, the mine operated the next day as usual.

WEST VIRGINIA

Wheeling—A canvass of the mining situation of the state shows that there are only about 50% of the miners at work at the present time. Of a total of 72,000 coal miners, there are but little more than 25,000 working. Unless there is a decided improvement in the iron industry, it is feared that these conditions will not be better before spring.

Morgantown—Only one day was allowed for the miners' Christmas by the Elkins Coal Co. Notices posted earlier in the week ordered back to work every miner on the 26th, and all but a few responded. Every mine of the company is running to capacity despite the fact that the coke market remains bad.

Prince—Work was recently begun for the operation of the old Royal mine at this place. The premises are being rehabilitated generally. The houses, tipples, tracks, etc., are undergoing repairs and the first property to ship coal out of Raleigh County will be shipping coal again before many weeks.

Elkins—A. P. Brady, formerly of the Brady Coal Co. will shortly take over the Leroy mines at Coalton owned by W. H. Green and operate the same. Mr. Green has made arrangements to operate the mine at Weaver.

KENTUCKY

Madisonville—It is reported in the western Kentucky coal fields that the interests which have been attempting to effect a consolidation of a number of the larger operating companies for several years, have practically closed a deal involving the transfer of about 5000 acres of coal lands in the Kirkwood field, and that other fields in that section will be taken up shortly. The statement is made that some of the money has been paid over for the deal just completed. C. H. Murphey has been working on the consolidation project for several years.

Lexington—At a recent meeting of the executive committee of the Kentucky State University, it was decided to begin the short course in mining enginering, which has proved very popular, on Apr. 1, instead of at the beginning of the summer term, as has been the practice heretofore. The change was decided upon in order to make the course better suited to the convenience of the miners who make up the greater number of the students.

TENNESSEE

La Follette—The strike at the Rex mines of the La Follette Coal, Iron & Railway Co. has been settled and the mines once more are in full operation.

ALABAMA

Birmingham—The Birmingham Railway, Light & Power Co. has closed a three-year contract with the Alabama Co. for approximately 140,000 tons per year of Lewisburg washed slack. This is one of the largest contracts in the South, and many of the operators were bidding on it. The contract is made on a guaranteed analysis, on the basis of a penalty and bonus clause.

OHIO

Shadyside—The Webb mine of the George M. Jones Coal Co., which is being opened near Shadyside, Ohio, will soon be ready for operation. Entries are being driven and from 40 to 50 cars a week of coal are being loaded therefrom. The material for the steel tipple is on the ground.

Columbus—Miners in Ohio are not assured of the passage of the anti-screen law as recommended by the Ohio Mining Commission, but will have to fight before the Ohio General Assembly to secure the passage of the bill. Operators announce that they will put up a stiff fight to prevent the enactment of the law which will give operators in other fields all the advantage.

A number of the larger employers of labor in Ohio, including quite a few coal operators, have elected to carry their own insurance under the new compensation law rather than to pay into the Ohio State Board of Awards a certain percentage of their pay-rolls. Rules for the corporations and individuals to carry their own insurance have been promulgated by the Board of Awards and the experiment will be watched with considerable interest by other coal concerns in the Buckeye State. The employer is compelled to settle all claims on the same basis as the Ohio State Board of Awards.

INDIANA

Bicknell—It is reported that two men were killed by an explosion of gas in the Indian Creek coal mine early on Dec. 29. Practically all the night shift of 150 men had just come to the surface when the explosion occurred. Work was immediately begun to recover the dead.

ILLINOIS

Springfield—Representatives of 50 Illinois mines recently met in Springfield and organized the Central Illinois Coal Operators' Association. This organization has as its principal object the carrying on of negotiations and effecting agreements with labor organizations interested in coal mining in central Illinois, furthering the safeguarding of life and property and advancing in every way the industry of coal mining. No mines affiliated with railroad companies are included in the organization.

De Soto—H. O. Ozburn, of Murphysboro, has been appointed receiver for the J. B. Kreikemeier Coal Co., at this place. The receivership was made necessary by the failure of the company to meet the pay-roll on Dec. 15, and the trustee for the bondholders applied for the receivership. The mine has been producing about 500 tons a day and is in excellent condition, but the property never made money for anybody, and several have lost fortunes in the past 10 or 15 years trying to operate it.

Murphysboro—Christmas in the mining districts of southern Illinois this season was perhaps one of the bluest that the miners have experienced for several years. Throughout the mining districts the Elks and other fraternal societies brightened the occasion by their liberal donations to those who were needy.

New Baden—The blacksmith shop, machine shop and storage room of the New Baden mine of the Southern Coal, Coke & Mining Co., of St. Louis, was destroyed by fire Christmas night.

ARKANSAS

Fort Smith—State Mine Inspector Shaw recently closed mine No. 2 of the Western Coal & Mining Co. at Denning. Failure of the company to comply with instructions relative to the construction of an air-shaft is given as the chief reason for closing the mine, which is one of the largest in this section of the coal field.

COLORADO

Trinidad—According to figures recently given out by local operators the coal production in the southern Colorado fields, is about 60 per cent. of the normal output.

Denver—It is reported from the coal mining district, where several thousand men have been on strike for some months that the industrial strike was forgotten on Christmas day and good-will prevailed. Christmas exercises were held in each of the strikers' tent colonies, huge Christmas trees being gaily decorated and loaded with gifts for the children, the United Mine Workers of America providing 8000 baskets of candies, fruits and sweets. In the militia camps also decorations were numerous.

FOREIGN NEWS

London, England—Among the most interesting of the specimens brought back by the Scott Antarctic Expedition are some pieces of coal found by Captain Scott's party in latitude 85° south in the middle of the frozen plateau that stretches from King Edward's Land to beyond the South Pole.

PERSONALS

F. J. Devlin, recently superintendent of the Santoy, Ohio coal mines, has been transferred to the superintendency of the Jones & Adams Coal Co.'s Peerless Mine, at Springfield, Illinois.

J. E. Beebe, formerly of the Black Diamond, has recently allied himself with the Old Ben Mining Corporation. The offices of his new employers are in the McCormick Building in Chicago.

William Moody, superintendent of the Sunnyside coal mines, near Evansville, Ind., and a well known figure in the coal trade in southern Indiana and western Kentucky, was stricken with paralysis a few days ago and is not expected to survive.

George Wolf, of Davy, W. Va., was recently appointed general manager of the Superior Pocahontas Coal Co. at Davy, and the Winding Gulf Colliery Co., of Winding Gulf. The latter firm has mines on the Chesapeake & Ohio and Virginian railroads.

William Hartman has been appointed mining inspector for the second district of Illinois, vice Thomas Hudson, of Galva, term expired. George L. Morgan, of Benton, has been appointed inspector for the tenth district, vice Thomas Little, of Murphysboro, term expired.

David Z. Thrush and Patrick Hogan of Farmington and Canton, Ill., respectively, have been appointed state mine inspectors. Mr. Thrush who at the present time is county mine inspector, succeeds James Taylor, of Peoria, who recently tendered to the governor his resignation.

Henry H. Otto, of Wilkes-Barre, has been appointed Division Engineer of the Lackawanna Division of the Lehigh Valley Coal Co., with headquarters at Pittston, to succeed G. P. Troutman, who recently resigned to accept the position of Assistant General Manager of Markle & Co.

OBITUARY

Thomas A. Ritson, a prominent citizen of Steubenville, Ohio, and one of the most experienced mine bosses in that section, died recently at Gill Hospital as the result of an operation. Both in Ohio and West Virginia, he repeatedly carried to a successful conclusion the work of clearing up and putting mines in shape after explosions and floods. It was in his work as a mine boss and expert that he was a valuable man to coal operators.

CONSTRUCTION NEWS

Johnstown, Penn.—A. W. Hoy was recently awarded the contract for building a tipple at the Park Hill Coal Co.'s plant above Conemaugh.

Zanesville, Ohio—The Blue Rock Run Coal Co. has recently started work on a coal mine on the Thornton Olden farm in Harrison Township.

Newport News, Va.—It is expected that the new steel coal pier which is being built at a cost of $1,500,000 will be completed on or shortly after Jan. 1, and will be immediately ready for the dumping of coal. This dock is the largest in the United States, being 1200 ft. long and having a capacity of 40,000 tons of coal daily. It is believed that at least two of the old piers will be abandoned when this one is completed.

Meyersdale, Penn.—A contract has been signed between the Brothers Valley Coal Mining Co. and the Penn Public Service Co. whereby by the middle of March, the former firm's large plant, near Berlin, will be operated by electric power furnished by the Service Co. The Brothers Valley Mines are now operated by electricity, steam and compressed air. The output is expected to be increased and at a less proportionate cost.

St. Louis, Mo.—Work was recently started on the $2,000,000 coke oven plant, which the Laclede Gas Light Co. will build on a 200-acre tract between South Broadway and the Mississippi River, Klausmann's Grove and Jefferson Barracks. The plant will have 56 ovens with a daily producing capacity of 750 tons. The coke will be made from Pennsylvania bituminous coal, brought to St. Louis on barges by way of the Ohio and Mississippi Rivers.

Millsboro, Penn.—Announcement has been made that Millsboro, which is in the center of the predicted coal and coke development of Washington and Greene counties is to have a new industry in the form of a powder and explosive plant of the Lowintite Explosive Manufacturing Co. A location has been secured upon the farm of James Allen and the plant will be in close proximity to the extensive coal fields which are just beginning development. It is planned to deliver powder by motor trucks within a radius of 20 miles.

Barbourville, Ky.—It is reported that the Louisville & Nashville is considering estimates on the cost of double-tracking its Cumberland Valley division, the additional trackage being necessary on account of the heavy coal traffic from the Harlan county field. The Harlan mines are now averaging an output of 160 cars a day, and this production will be largely increased in the future. It is said that about 600 cars of coal a day from the several southeastern Kentucky fields pass Barbourville for Corbin, Ky., where they are transferred for movement north or south. This heavy movement has become so difficult to handle that it is interferring with the passenger traffic, and the company has come to the conclusion that double-tracking is the only solution of the problem.

Norton, Va.—An extension by the Southern Ry. of its line now terminating at Norton, Va., operated by the Interstate Railway Co., is the latest railroad project announced for the purpose of giving the eastern Kentucky coal field an outlet to the Atlantic coast. The extension which seems to have been definitely approved, will pass through the headwaters of Guests' River and the Pound River, both of which are important coal and timber districts of Wise County, and thence through Pound Gap into Kentucky, a total distance of about 25 miles. It is stated that the construction of the road will be started within the next 60 days. Other projects which have been discussed recently are still on the program, and it seems certain that several new lines will be completed into eastern Kentucky during the coming year.

NEW INCORPORATIONS

Cincinnati, Ohio—The Murdock Coal Co. has applied for permission to increase its capital stock from $10,000 to $20,000.

Scranton, Penn.—The Plymouth Red Ash Coal Co. was recently incorporated under the laws of Pennsylvania with a capital stock of $10,000.

Hazard, Ky.—The Eastern Kentucky Coal Co. has been organized with a capital stock of $250,000 to develop 40,000 acres of coal land in Perry County.

Rockford, Ill.—Samuel G. Duran, of Philadelphia, Fayette S. Munroe, of Harlem Park, Ill., and others have formed a company to build a steam railroad to tap the coal field of Kankakee County.

St. Louis, Mo.—A license to do business in Missouri has been granted to the Staunton Coal Co. organized under the laws of the State of Illinois with a capital stock of $300,000 and offices in St. Louis.

Richmond, Va.—The Himyar Coal Corporation has been organized in Richmond with a capital stock of from $25,000 to $50,000. T. L. Young is president, L. C. Derrickson, secretary and treasurer, both of Lexington, Ky.

Herrin, Ill.—The Herrin Coal Co. has been chartered with a capital of $4500 to engage in a mining, mercantile and manufacturing business. The incorporators are Paul B. Herrin, John Herrin, H. P. LaMaster and A. E. Elles.

Frankfort, Ky.—Articles of incorporation for the Coal, Oil and Gas Co., of St. Matthews with a capital stock of $60,000 have been recently filed. The incorporators are A. J. Fraley, of Wrigley, L. M. Render, Louisville, and John P. Haswell, Jr., of Hardingsburg.

Joplin, Mo.—The Melva Mining and Milling Co. of Joplin has filed articles of incorporation with a capital stock of $30,000. The principal stockholders are L. M. McGuire of Kansas City, J. W. Commerford, of Joplin, S. A. Kellar, of Joplin, Mark Ramsey, of Joplin.

Charleston, W. Va.—The Profound Number Five Coal and Mining Co. has been organized at St. Albans for the purpose of operating coal mines in Boone County. The capital stock is $60,000 and the incorporators are J. F. Thompson, Dr. A. E. Winters, R. M. Figman, W. B. Lauder, W. H. Lauder and I. J. Williams.

Toronto, Canada—An adjourned special general meeting of the shareholders of the Intercolonial Coal Mining Co., Ltd., was held at Montreal on Dec. 18. The Board of Directors reported that satisfactory financial arrangements had been effected for carrying on the operations of the company without the necessity of issuing any further securities at present. D. Forbes Augus having resigned the presidency, Charles Fergie, M. E., was elected president and managing director.

INDUSTRIAL NEWS

Wilkes-Barre, Penn.—The old Enterprise mine in Plains Township, which was abandoned on Nov. 18, 1889, will shortly be reopened.

Pottsville, Penn.—Engineers have recently made surveys at the Ellangowan and Suffolk collieries with the intention of taking a thousand feet of coal from the former to the latter's opening.

Indiana, Penn.—A $60,000 coal deal between the Operators Coal Co., of Johnstown, and the residents of West Wheatfield Township, has just been consummated. Work will be started shortly on the opening of a mine with New Florence as the center of operation.

Fairmont, W. Va.—A team from the Consolidation Coal Co. and one from the Jamison Coal & Coke Co. have finished the work given by those in charge of Mine Rescue Car No. 6, of the U. S. Bureau of Mines, now located at Chiefton. Both teams showed much natural aptitude for the work.

Birmingham, Ala.—The Pratt Consolidated Coal Co. will furnish the New Orleans Street Railway, Light & Power Co. with its coal for the coming year. This contract calls for 125,000 tons, and the needs will likely go to 175,000 tons. Shipments will be made daily beginning the first of January.

Briceville, Tenn.—The Knoxville Iron Co. offers for sale as a whole for cash its Cross Mountain Mine, at Briceville, Anderson County, Tenn., and all real estate appertaining thereto or used in connection therewith including houses, commisaries, mules, cars, chutes, engines, boilers, stables, feed and all other equipment.

Charleston, W. Va.—Governor Hatfield will likely be called upon to settle a controversy existing between the Signal Knob Coal Co., of Ansted, and the miners who have been on strike since Sept. 1. The conciliation board failing to reach an agreement on the matter has ordered that the case be presented to the governor for adjustment.

New Orleans, La.—The Alabama & New Orleans Transportation Co. has just launched at its ship yard near New Orleans, the fifth of its steel coal barges. These boats are self-propelling and have a capacity of 1000 tons each. The sixth barge is nearing completion and will be launched in the near future. Several additional barges have been started.

Belvidere, Ill.—The Chicago & Northwestern R.R. is storing coal in the local yards at the rate of five cars per day and will continue to thus accumulate fuel until 10,000 tons are in storage. This action is taken by the transportation company as a precaution against a possible strike of the miners next spring when new contracts are to be drawn up.

Pittsburgh, Penn.—With the close of navigation on the Great Lakes, railroads operating to ports on Lake Erie having little use for their coal and ore cars are trying to induce the iron mills in Ohio and Pennsylvania to make use of them. Unfortunately the need of cars for immediate shipping purposes for this class of traffic has lessened considerably and it is not easy to obtain such freight.

Charleston, W. Va.—Antonio Cirvallo and others who sued the Cabin Creek Consolidated Coal Co. for $15,000 for alleged injuries in being ejected from company houses during the recent strike in that section, lost their case recently. It was alleged that the wife of an Italian was mistreated and that the company had employed a number of guards to eject the miners. It took the jury but a short time to reach the verdict of "not guilty."

Pomeroy, Ohio—The leasehold and all the equipment of the Hartford Coal & Mining Co. was recently sold by the deputy sheriff to satisfy a judgment in favor of the Pomeroy National Bank for $5,577.50. There were three other judgments outstanding against the company, which run the total claims up to about $6000. The property and leasehold were offered as a whole and were purchased by E. D. and Mrs. Jennie M. Newton for the sum of $6500.

Columbus, Ohio—According to State Senator J. B. Dollison, of Logan, Ohio, practically every coal mine in the southern part of the state has closed because the operators are unable to compete with those of West Virginia by reason of discriminatory freight rates. The senator estimates that 10,000 men are out of employment. The State Public Utilities Committee has been ordered to investigate the charge of alleged discrimination in freights.

Pineville, Ky.—Announcement has been recently made that a deal has been consummated between the Continental Coal Corporation and certain Tennessee parties by which the latter have taken over three coal mines at Four Mile, on Jellico Creek. More than $1,000,000 is involved in the deal. The new corporation will be known as the Four Mile Coal Co. and W. M. Woods, who has operated mines in this district, will be the manager of the new concern.

Charleston, W. Va.—Photographs and motion pictures are being made to play a part in the educational system now being developed by the coal operators in West Virginia to lessen the number of mine accidents, increase efficiency at the mines and add to the earning capacity of the miners. Although this is by no means a new idea, it is said that in no other way have the companies been able to bring home to the men the danger and the need of caution.

Charleston, W. Va.—The report of Earle Henry, Chief of the Bureau of Mines, recently made public, shows one death from accident for every 700,000 tons of coal mined in six of the coal-producing counties of West Virginia during the first eleven months of 1913. In ten coal counties, there were no deaths from mine accidents. Total deaths in the mines of the state number 309 compared with 340 for the same period last year, the number of miners employed being increased approximately 5000.

Helena, Mont.—The Montana State Railroad Commission has started to investigate the coal rates charged by the Great Northern R.R. from the Bear Creek and Roundup coal districts to the various cities of that state. The first hearing will be held at Billings on Jan. 6. The investigation is started by the commission on its own motion, because of the complaints it has received from residents of the state who desire to use Montana coal, but on account of the excessive rates, are forced to use either Canadian or Wyoming coal.

Columbus, Ohio—A mine-rescue car, equipped with all the latest appliances for rescuing miners entombed as a result of explosions, cave-ins, or other causes, has just been purchased by the state utilities commission from the Pullman Co., of Chicago, for $3000. The new car is to be delivered just as soon as completed. It will be equipped with a naptha tank, 12 sets of oxygen breathing apparatus, 1 recharging device, 12 extra oxygen cylinders, 40 approved safety lamps and in fact everything necessary to aid the rescuers in saving the lives of entombed miners.

St. Louis, Mo.—The Missouri Supreme Court, in an opinion, declined to rescind the contract under which Miss Anna B. Haldiman, of Versailles, sold to Jos. E. Ryan and C. C. Magenheimer, 5111 acres of land in Morgan County, Mo., for $55 an acre. The two above mentioned plaintiffs and the Morgan County Coal Co. sued to rescind the deed upon the ground that the defendant, through her agents, represented to them that the land was underlaid with coal, and it later developed that it was not. The court directs a verdict of $31,920 for the defendant, claiming the plaintiffs waited too long before suing and before they made tests to determine whether or not the property was underlaid with coal.

Coal Trade Reviews

GENERAL REVIEW

Lower temperatures and holiday curtailment at the mines inject a better tone into hard coal, although market is still heavy. Production may be further restricted. Softening tendency in bituminous continues. Considerable coal on hand and indications point to a slow recovery.

Under the combined influence of a heavily curtailed production over the holiday period, and a sharp decline in temperatures, the general tone of the anthracite trade is improved. Consumers are evidencing some interest in supplies and coal is moving more freely. Conditions are, however, generally unsatisfactory. The customary holiday demand failed utterly to materialize, with the result that the companies still have large stocks on hand, and a further curtailment in mining will be necessary unless the situation is relieved by a long period of cold weather.

There has been little change in the soft coal situation and the trade rounded out the year in poor form. Business is dull and heavy, and in distinct contrast to the summer and early fall. While prices have been tentatively held at some points, the general demand is so light that there has been a perceptible tendency toward a further softening. The holidays have apparently retarded industrial demands. The only encouraging feature is the reduced production over the holiday period, and consequent light shipments to the consuming markets. A comparatively long period of fairly cold weather will be necessary to reëstablish the trade on a firm basis.

Mine operations in the Pittsburgh district were much reduced over the holidays, but general industrial and manufacturing were equally curtailed; while prices are fairly well maintained, there are heavy offerings at the circular and indications point to a further decline. Ohio mines have scarcely worked 50% capacity during the past two weeks, but even under these conditions it has been difficult to place the tonnage. Optimistic reports indicate a greater industrial activity after the first of the year, but more seasonable weather conditions will be required to put the domestic business on a firm basis. Prices are comparatively steady with cutting confined principally to the smaller companies.

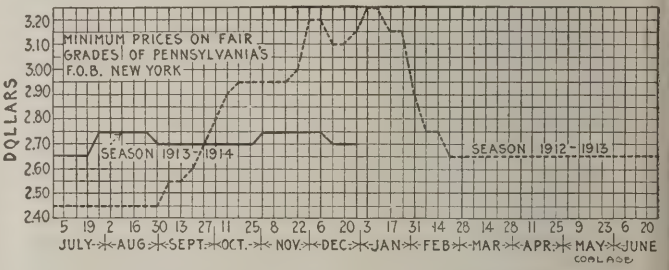
Some hard winter weather has injected a slightly better feeling into the Southern trade, although this has not been of sufficient duration yet to be felt in the operating departments. An important increase in the freight rate on coke to the Western smelters created a slight flurry on the part of consumers desirous of accumulating stocks at the old schedule. Colder weather has also stimulated business in the Middle Western market, but with unusually large supplies on hand and a scarcely perceptible demand, the recovery will be slow. The trade has seldom ever reached such a low ebb in the fall of the year, and the only encouraging feature is the fact that prices have shown such a stubborn resistance on the decline. With more cheerful reports regarding general industrial conditions after the first of the year, there is a better tone in the market than for some time.

EASTERN MARKET

NEW YORK

Improved tone to anthracite under more seasonable weather conditions and curtailed mining. Stocks on hand still heavy. Bituminous holding moderately firm in spite of the large amount of coal at tide and a generally light demand.

Anthracite—Reports show that the stocks in the hands of the retail dealers are still heavy, and buying in consequence is light on all of the domestic sizes, but continuance of the cold weather will, no doubt, stimulate buying. The general tone under the improved weather conditions is much better. The storage capacity of most of the local dealers is such that large stocks cannot be carried to advantage, and the business is effected almost directly by temperature changes.



Egg contnues to be the weak size, selling as much as 50c. off circular in some cases where offered alone. Stove and chestnut are moving fairly well at, or about circular prices. Pea continues quite active on the line, but is not strong at tidewater. No. 1 buckwheat is easy, while No. 2 and No. 3, more especially in the high grades, are short; in poorer grades, Schuylkill and Lehigh, are offering freely.

Most of the operations closed down from Christmas eve until Monday. Some endeavored to work Friday and Saturday, but the men did not come out in large numbers and the result was practically no tonnage. Under present conditions, stoppage of this kind is healthy for the business; as there will probably be a recurrance of this situation over the New Year holidays, conditions should be much better after first of the year.

We quote the New York market on the following basis:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.00	.....	$5.05	
Egg	5.25	$5.25@5.35	5.30	$4.75@5.20
Stove	5.25	5.25@5.40	5.30	5 20@5.35
Chestnut	5.50	5.40@5.50	5.55	5.35@5.45
Pea	3.50	3.40@3.50	3.50	3.35@3.45
Buckwheat	2.75	2.70@2.75	2.45@2.70	2.25@2.70
Rice	2.25	2.25	1.95@2.20	1.80@2.20
Barley	1.75	1.60@1.75	1.70	1.40@1.70

Bituminous—The soft-coal situation remains practically the same. There is a considerable amount of coal on hand at New York loading ports, but prices have not changed materially even in the face of the light demand. The general embago on shipments to South Amboy was lifted 24 hr. after it had been in effect, and only a few of the shippers are now subject to the restriction.

As the mines worked only about three days during Christmas week, and as the celebration continued well into the current week, arrivals at tide are now light. The normal winter weather in the mining regions and colder temperatures in the consuming centers should have a beneficial effect on the situation.

Pending the probable increased demand, due to the approach of the period for negotiations between the miners and operators on the subject of the new scale of wages, to be effective Apr. 1, the only stimulus is likely to come from more severe weather conditions. Quotable prices remain as follows:

West Virginia steam, $2.60@2.75; fair grades of Pennsylvania, $2.70@2.80 good grades of Pennsylvania, $2.80@2.90; best Miller Pennsylvania, $3.10@3.20; George's Creek, $3.15@3.25.

PHILADELPHIA

Anthracite fails to show any improvement in spite of curtailed mining and more seasonable weather. Large stocks still on hand and further curtailment in production seems probable.

Despite the fact that there has been curtailed mining, and some more seasonable weather the expected increased demand for coal has not materialized. It is true that the enforced reduction in the output has taken care of some surplus that had accumulated, but it was not found necessary to dip into stocks on the ground. Anthracite men are at a loss to explain the slump in the market, particularly at this season of the year. It is understood that many of the companies still have large stocks of pea coal on hand which have usually disappeared by this time in normal years.

It is certainly a fact that within the last ten years, no such experience has been undergone as characterize conditions now. Even stove coal has become easy, in the face of reduced output. Unless there is a continuous spell of cold weather for at least a month, conditions are in no way likely

to improve. The dealers in general seem to have ample supplies of all sizes of coal, many of them complaining that their stocks hardly give them a chance to move around. The advance in prices effective about the first of December, still continue to be generally observed by the retail trade. Further curtailment of mining is likely, if conditions do not improve in the near future.

Bituminous trade still continues to hold forth no promise, and good coals are being offered at prices that hardly show a profit for the mining. Large quantities are still coming to market, and are practically forced on the consumer by prices that they can hardly resist. It looks as though the same conditions that will add a little snap to the anthracite, will stir up things in the bituminous as well, and until that time comes, no improvement is looked for.

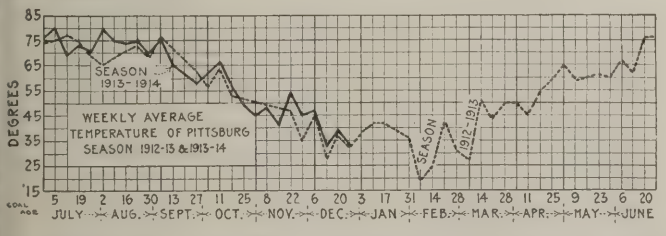
BALTIMORE, MD.

Year closes in dull form. Mine production cut due to holidays. Prices are still uncertain, and the demand light. Colder weather helps anthracite trade.

Soft coal interests rounded out the last week of the year 1913 in rather dull form. The state of the trade was a distinct contract to the busy period during the summer and the early fall, which contributed to make the year a successful one as a whole. The holidays cut heavily into mine production, Christmas week being light in all regions. This was rather welcomed all along the line, however, in view of accumulations that have begun to show up.

Prices are fluctuating badly, as was the case last week. Slack has taken a new slump, and was offering in West Virginia as low as 65 and 70c. Gas run-of-mine was around 80c. and three-quarter at 85c. to the trade. Best Georges Creek could be bought at about $1.50, and other fine Pennsylvania coals that were selling a few weeks ago at $1.40 to $1.45 are offering at $1.25. Demand continues light, the holiday season having apparently still farther retarded the industrial situation generally.

Coke is heavy, Connellsville furnace selling down to $1.85 in some instances, and West Virginia furnace 10 to 15c. off that low price.



A number of foreign loadings were recorded the last month of the year, and it is expected that the export figures will run about 200,000 tons in excess of those of 1912.

CENTRAL STATES

PITTSBURGH, PENN.

Coal demand light and prices somewhat unsteady; mine operations reduced on account of the holidays. Connellsville furnace coke stronger than expected, with some sales for 1914 at $2. Foundry coke slightly easier.

Bituminous—Mine operations were at a reduced rate last week, on account of the holiday celebration, and probably less than 50% of the full tonnage was shipped, against a rate of about 60% maintained before the holiday interruption. Demand from manufacturers has been particularly light in the aggregate as a great many mills closed over the holidays and domestic demand has been light except for a little spurt in the past two or three days. Prices are fairly well maintained, but there are heavy offerings at the regular level, which we continue to quote as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The furnace coke market is doing much better than expected. The offerings of coke at less than the $2 price asked by a majority of operators proves insufficient for the demand, partly because a considerable portion of the lower priced material is not altogether up to standard in quality, and several purchases have been made at the full $2 figure, though as a rule for only January or three months. However, one operator is refusing to sell beyond March at the figure, using $2.10 for second quarter. In the past week prospects have been that the cheap coke would all be cleaned up and the market firmly established at $2, but latest information is that Corrigan, McKinney & Co., whose requirements for their six blast furnaces amount to about 75,000 tons a month, have decided to blow out their five active stacks at once, presumably because they are unwilling to pay prices asked for coke. Foundry coke has softened about 10c. We quote: Prompt furnace, $1.75@1.85; contract furnace, $1.90@2; prompt foundry, $2.40@2.65; contract foundry, $2.40@2.65, per ton at ovens.

The "Courier" report production in the Connellsville and lower Connellsville region in the week ended Dec. 20 at 284,964 tons, a decrease of 22,826 tons, and shipments at 278,355 tons, a decrease of 27,490 tons.

BUFFALO, N. Y.

Better coal weather, but still no great activity. Reports show that dealers and consumers are overstocked with both anthracite and bituminous. Slight move in coke. Christmas shutdown will relieve the tension in the market.

Bituminous—There is a showing of more seasonable weather and the feeling is better, but dealers find that there is such an overstock of all sorts of coal that it will take a long time to establish a really firm basis. The bituminous trade has been pushed so much more actively than conditions justified that buyers have no room to store more coal. This is reported from all sides.

There is not much coal being produced now and it is estimated that there will be a shutdown in all the Pennsylvania districts that should amount to a full week; this will do something toward relieving the tension. Shippers now say that there is nothing that will help the situation now but weather severe enough to increase the consumption very materially.

There is not much unsold coal on track here and some jobbers report the filling of good-sized orders. While the railroads are not taking coal in large amounts some of the mines are able to keep going on railroad orders alone. The bituminous market is at least no weaker than it was, the basis remaining as before.

Coke—There is a report from Connellsville that the situation has improved a trifle in the past week. The demand is somewhat heavier and shippers are refusing to take long-time contracts. This is the first indication of improvement in coke for a long time and it is to be hoped that it will continue. The prices are on a basis of $4.60 for 72-hr. Connellsville foundry.

Anthracite—There is a slight stir in domestic sizes of anthracite and if cool weather should continue the market would right itself soon. Still some of the shippers report considerable amounts on track which they must dispose of to avoid demurrage. The surplus that comes here can go into lake vessels for the winter, but the shipping agents much prefer to sell it now, at the higher prices. After Feb. 1 anthracite is to be placed completely on the demurrage list; the practice of allowing it to stand on track indefinitely in case it is waiting for reconsignment will not be permitted any longer. It is hard to understand why such coal has ever been exempted. Four or five lake cargoes for winter storage have so far been loaded, all by a single shipper, with more tonnage under charter.

COLUMBUS, OHIO

Combination of the holiday season and continued mild weather has made trade quiet. Dealers in all sections are over-supplied and domestic trade is dull. Let-up in steam business and cessation of lake shipments have affected the trade in all districts.

Many operators in Ohio closed their mines the day before Christmas for the remainder of the week. Others, who tried to operate, were generally without orders and the production was at a low point. In the Hocking Valley field the output is estimated at 40 per cent. and the same percentage is reported from the Pomeroy Bend district. In eastern Ohio there was also a scarcity of orders and 35 per cent. will cover the production. The other fields produced only a small part of the usual tonnage.

Prices have remained rather firm at the levels which have prevailed for some time. The larger operators are not disposed to cut quotations below the circular but the smaller fellows are shading prices and as a result the coal that is moving, outside of contracts, is at lower figures than the circular.

Stopping of many manufacturing enterprises during the holiday season together with the general slow-up in business has affected the steam trade adversely. Railroads are not taking much fuel at this time because of the small movement. It is believed there will be an improvement in business soon as many plants may resume operations after the holiday season.

Retail trade is slow because of the continued unfavorable weather. There is a good demand for some fancy grades but this will probably be only temporary unless the weather becomes more favorable. Bins are full and most of the large users have laid in their supply of fuel for the winter. The market is now entirely at the mercy of the weather.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.85 @ 1.75	.....	$2.00 @ 1.85	$1.70 @ 1.60
3-4 inch	1.65 @ 1.60	$1.20 @ 1.15	1.80 @ 1.70	1.50 @ 1.45
Nut	1.40 @ 1.30	.....	1.65 @ 1.55	1.40 @ 1.30
Mine-run	1.40 @ 1.30	1.10 @ 1.05	1.30 @ 1.25	1.40 @ 1.30
Nut, pea and slack	0.80 @ 0.75	.....	0.90 @ 0.85	0.80 @ 0.75
Coarse slack	0.70 @ 0.65	0.90 @ 0.80	0.80 @ 0.75	0.70 @ 0.65

DETROIT, MICH.

Some activity in domestics but trade generally quiet. Steam consumers out of the market. Operators holding prices moderately firm.

Bituminous—A number of manufacturers have closed down, while others are running on short time so that steam business is at a minimum. Consumers are showing no disposition to accumulate surplus stocks while in some instances consignments arriving on contracts are being refused.

Some improvement is noticeable in domestic grades, but stocks are large and generally speaking dealers are prepared for almost any emergency that may arise. Operators and jobbers are making determined effort to maintain circular quotations, but prices are unsteady on all grades. Smaller companies are showing a tendency to force business by cutting prices and while nominal quotations are: $1.85@$2 on the Hocking domestic lump, with Pomeroy at $2.15@2.25, and Kanawha $1.75, any of these grades can usually be had for prompt shipment at $1.40.

The market is quotable on the following basis:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump	$1.75	....	$2.00	....	....	$2.50	$2.50
Egg	1.75	....	2.00	....	....	2.50	2.50
Nut	1.10	....	1.15	....	....	....	....
Steam lump	1.20	....	....	....	....	....	....
¾-in. lump	1.10	$1.10	1.10	$1.10	$1.10	....	....
Mine-run	1.00	1.00	1.00	1.10	1.10	1.40	....
Slack	0.85	0.85	0.65	0.80	0.75	....	....

Anthracite—Consumers all appear to be over-stocked on hard coal and demand has ceased entirely. The trade is marking time pending the arrival of more continued cold weather.

LOUISVILLE, KY.

Some hard winter weather has injected a better feeling into the trade. Effects not yet felt in the operating departments which are under curtailed production because of the holidays.

Christmas brought a pronounced cold snap, which made people realize that winter had arrived. A good deal of snow fell, accompanied now and then by a freezing rain, and the weather has held well since, so that the trade is looking forward confidently to some real business from now on.

As yet the demand expected to result from the improved weather conditions has not materialized, which is just as well considering the usual holiday lay-off at the mines; little coal has moved of late, so that the market condition fitted in nicely with the small supplies available. The relatively light demand reported by the retail trade indicates that the stocks laid in early in the season are, in most instances, still on hand. This will hold up the demand for a few days, but the trade is bound to feel the effects of the improved consumption shortly.

Domestic prices have shown a stiffer tendency as a result of better prospects for business, quotations for January delivery of good Eastern Kentucky coal being $2.25 for block, $2 for lump and $1.75 for egg. The steam market is in a rather anomalous state, due largely to the dealers themselves. The low production of the prepared grades has kept down the amount of screenings available, which has maintained prices but in spite of this some dealers have recently shown signs of making concessions. This condition will probably disappear, however, with a more active movement of domestic, and a continued upward tendency on both sides of the market may be expected.

SOUTHERN AND MIDDLE-WESTERN

BIRMINGHAM, ALA.

Little change in the coal market. Furnace coke somewhat more active with larger shipments. Pig iron quiet, though price holding firm at $11. Car supply shows improvement.

The coal markets, both steam and domestic, show little change over last week. There is small demand for either grade, though lump coal has slightly improved. The usual holiday business did not materalize, which was a disappointment to the operators; ordinarily the mines are rushed to full capacity during this time, and while a few companies had orders for extra billing, the operators as a whole received no benefit. A good many of the mines are closed down for a few days, the producers taking advantage of the quiet market and not asking their men to report back for work until Dec. 29.

Due to the advance of $2 per ton on coke to Western points, which goes into effect on Jan. 1, many of the Western smelters have placed orders for a good tonnage of furnace coke for shipments prior to that date, and this has greatly assisted in keeping the coke market in a satisfactory condition. Foundry coke is quiet, and some producers are offering 72-hr. foundry as low as $3.75. The regular price is from $4 to $4.25 per ton. No large sales of pig iron are being made, though many small orders for prompt shipment are coming in. The price is holding up on the basis of $11 for 2F f.o.b. Birmingham.

Due to the quiet trade, and the fact that many of the mines closed down for a few days during the holidays, the car situation shows some improvement.

INDIANAPOLIS

Little change in situation. Mild weather continued almost to the end of December. Sentiment more cheerful at coming of January. Prices unchanged.

The month of December was an unusual one in its mildness and it is seldom that so little coal is necessary. The one comforting condition to the trade was that prices held up. It seemed useless to cut them for buyers simply did not need the coal and were afraid to take on more, even at low figures. This was not true of screenings at first and they were practically given away but the slow demand for the larger coal finally compelled the closing of mines; then screenings and other steam grades became scarce and prices were pulled back to somewhere near normal.

As railroads were retrenching near the end of the year, so that their annual reports might make as good showing as possible, there may be improvement in the service from now on. Under the urgings of the Indiana Public Service Commission, the railroads have succeeded in relieving the congestion at important points and the situation is quite favorable as the new year starts. Industrial conditions are not bad locally and an optimistic tendency is noticed since the currency question was settled.

The year 1913 will be easily remembered by coal men because of the unparalleled floods in March that carried away much coal, shut down factories and filled mines with water. In this city, two memorable strikes occurred and few of the coal men will forget the summer weather that continued up to Christmas.

CHICAGO

Return of lower temperatures brightens outlook for coal dealers. Expected that recovery from dull conditions will be slow. Little demand for lump coal and screenings market is not strong. Small amount of anthracite being disposed of and few sales of Hocking. Smokeless dealers report slack business. Coke market slow.

Return of colder weather has brought Chicago coal dealers hope for greater briskness in business, although it is expected that the recovery will be slow. Conditions in nearly all lines continue unsatisfactory.

The demand for lump coal is scarcely noticeable, all dealers having their bins well stocked; few operators are producing much in the larger sizes. There are unusually large supplies of anthracite in the hands of the dealers and the demand continues light. Little of this coal is being forwarded from the docks to the interior. Standard shippers of Hocking are maintaining the circular price of $2 a ton with few sales being recorded. Other producers have offered $1.50 on shipments direct from the mines, but this inducement has not resulted in materially increasing sales. Some free coal up to car service has been sold as low as $1.40.

Carterville operators report that conditions are stationary. Some of them are running their mines on a steam-coal basis or have closed down where no orders for the output are on hand. In the Springfield market most of the domestic coal is being held at $1.50. Many of these producers are closing down rather than ship on consignment. Some improvement has been noted in the demand for screenings.

Weakness prevails in the smokeless lump and egg market and some producers will ship a car of lump and egg on a mine-run order rather than shave the price. There is better call for the mine-run as there is a continuous demand from apartment house owners. Standard shippers have kept the

ine-run price at $1.40, while some thin vein and off-grade al has been disposed of at $1.25. The market for screenings would be better if factories were not running on short me.

Prevailing prices at Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
omestic lump	$2.32	$2.45@2.80	$2.27	
eam lump	1.97		1.97	
gg		2.45@2.80		$4.30
ine-run	1.87	2.30	1.87	3.45
reenings	1.42	1 75@1.85	1.37	

Quotations on Harrisburg coal are: Domestic lump and gg, $2.55@2.85; steam lump, $2.25; mine-run, $2.25; screenings, $1.75@1.85; No. 1, nut, $2.55@2.85; No. 2, nut, $2.55.

Carterville prices are: Lump, egg and No. 1 washed, $2.55@85; No. 2 washed, $2.55.

Coke—Connellsville, $5.25@5.50; Wise County, $5@5.25; yproduct, egg, stove and nut, $4.90@5; gas house, $4.75@85.

ST. LOUIS, MO.

Indications point to an advancing market. Weather colder ith good future prospects for domestic inquiries. Steam zes holding up good. On anthracite, coke and smokeless the arket is slow and soft.

A little colder weather caused a toning up of the mar-t during the last days of the year. The first snow came hristmas Day, and while it was only light, it seemed to have ie effect of helping business along, and the dealers received ders; while they were not large ones, they were still sufficient to keep things moving, and there has been a slight mand for all grades of domestic coal. It has not made ie market as good as the operator would like, but coal is oving which is something that could not be said for it for ie past two or three weeks.

There seems to be a little demand right now for anthracite, and strange to say it is somewhat hard to get, although it a week or ten days ago the market was demoralized. oke is heavy, with no chance of picking up, and the same pplies in a way to smokeless.

In the local coals, screenings from both the Carterville and andard fields are still holding up, the former at 60 to 65c. id the latter at 45 to 50c. the mines. The nut sizes are agging; No. 1 raw has gone as low as $1, under demurge, and No. 2 at 90c., but the general market is considably better.

Indications are that after the first of the year there will a stiffening up on all sizes, and operators are not selling uch in advance.

The prevailing market is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
in. lump				$0.95@1.10
in. lump			$1.40	
in. lump	$1.25 @ 1.50	$2.25	1.50	1.15@1.25
mp and egg	1.85 @ 2.15			
o. 1 nut	1.15 @ 1.40			
reenings	0.40 @ 0.50			
ine-run	1.10 @ 1.20			
o. 1 washed nut	1.75 @ 1.90	2.25	1.60	
o. 2 washed nut	1.35 @ 1.50		1.25	
o. 3 washed nut	1.15			
o. 4 washed nut	1.05			
o. 5 washed nut	0.50			

Franklin County and Carterville 6-in. lump and 3x6 egg, .25@1.50; No. 1 nut, $1.15@1.40.

Quotations on anthracite are: Chestnut, $7.54; egg and ove, $7.28; grate, $7.02.

Smokeless lump and egg is quotable at $4.75@5.

Gas house coke is $4.85@5 with byproduct $5 to 5.15.

KANSAS CITY, MO.

Little activity over the holidays. Colder weather depleting stocks and outlook is brighter. Mine operations heavily rtailed.

Though the past week saw little activity in mining circles Kansas and Missouri, the prospects are now regarded as ing a decided improvement over those of the last couple months. The weather is more favorable and dealers' ocks are being rapidly depleted. This heavier consumption expected to affect wholesalers, early in the near year, alers apparently having waited for the turn of the year fore renewing their stocks. Few mines have worked more an half time during the holidays, while many operated only about one-fourth of their capacity.

The market has held steady but an advance is likely, if e situation continues to improve. Residents of Missouri id Kansas have practically abandoned their efforts to burn as for fuel, and coal will be used almost exclusively, both for domestic and commercial use during the winter, in marked contrast to the conditions in previous years.

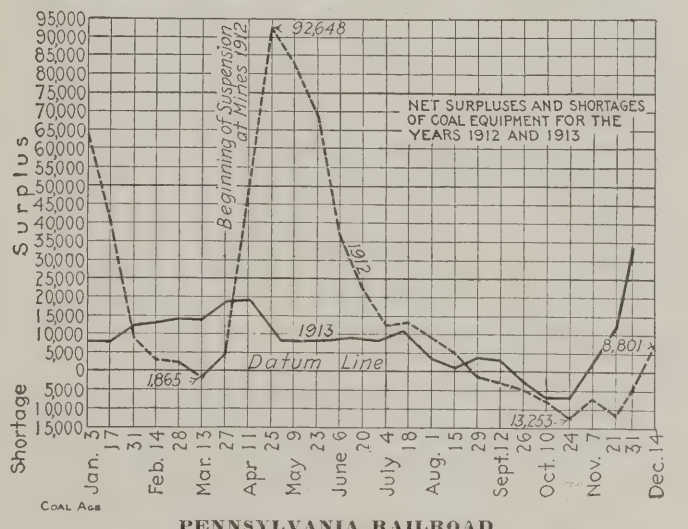
PORTLAND, ORE.

No change in market conditions although demand is a little stronger due to the colder weather.

There has been no material change in the coal market here excepting perhaps that the demand is a little stronger with the advance of winter. So far little really cold weather has been experienced here as yet, but in anticipation of what may follow soon after the first of the year, supplies are being laid in to last through the colder months, January and February.

The Monarch Coal Company which operates a new mine in the vicinity of Centralia is now shipping coal into this territory. It has established an office and the retail prices are: Lump, $6; egg, $5.75; nut, $5.50.

PRODUCTION AND TRANSPORTATION STATISTICS



THE CAR SITUATION

American Ry Association reports surpluses and shortages of coal equipment for two weeks ended Dec. 15, as follows:

	Surplus	Shortage	Net*
New England Lines	175	0	**175**
N. Y.; New Jersey, Del.; Maryland; Eastern Penn.	2,062	0	**2,062**
Ohio; Indiana; Michigan; Western Pennsylvania	18,201	0	**18,201**
West Virginia, Virginia, North & South Carolina	689	2,124	1,435

PENNSYLVANIA RAILROAD

The following is a statement of shipments over the P. R.R. Co.'s lines east of Pittsburgh and Erie for November and first eleven months of this year and last year in short tons:

	November		Eleven Months	
	1913	1912	1913	1912
Anthracite	987,487	916,914	9,699,210	9,275,631
Bituminous	4,509,375	3,934,876	47,171,538	42,162,485
Coke	999,500	1,245,500	13,011,863	12,128,463
Total	6,496,362	6,097,290	69,882,611	63,566,579

BALTIMORE & OHIO

The following is a comparative statement of the coal and coke movement over this road for November and the first eleven months of this year and last year:

	November		Eleven Months	
	1913	1912	1913	1912
Coal	2,939,975	2,864,734	32,091,742	29,140,169
Coke	343,387	435,001	4,350,800	4,318,122
Total	3,283,362	3,299,735	36,442,542	33,458,291

COAL MOVEMENT

The following is a summary of the movement of coal and coke over 13 principal railroads during October and the first ten months of this year in comparison to last year, in short tons:

	October		Ten Months	
Anthracite	1912	1913	1912	1913
Baltimore & Ohio[1]	184,252	166,214	1,267,222	1,226,938
Chesapeake & Ohio[1]	1,440	1,645	20,711	14,639
Erie[3]	761,360	794,528	6,202,725	7,283,826
Pennsylvania[1 3]	970,880	1,046,703	8,358,717	8,711,723
Virginia[2 1]	77	50	97	909

[1] Includes coal from connecting lines.
[2] Includes company's coal.
[3] Does not include company's coal hauled free.

Note.—The Southern Railway hauled 351,220 short tons of coal during September, 1913, and 3,127,282 short tons during the nine months ending September 30, 1913.

COAL FREIGHT DECISIONS

Suspension Docket No. 181—Rates on coal to Milwaukee and other Wisconsin points.

The holding of the original opinion, 27 I. C. C., 223, as to the maintenance of routes and rates for the transportation of soft coal from certain West Virginia and Kentucky mines to points on the west shore of Lake Michigan, when destined to points beyond, is affirmed. An advance of 10c. per ton in the proportional rates here in question is likewise permitted.

FOREIGN MARKETS

GREAT BRITAIN

Dec. 19—The coal market continues strong in tone with large coals scarce. Quotations are approximately as follows:

Best Welsh steam	$4.98@5.16	Best Monmouthshires	$4.44@4.50
Best seconds	4.80@4.92	Seconds	4.14@4.26
Seconds	4.56@4.74	Best Cardiff smalls	2.64@2.70
Best dry coals	4.56@4.80	Seconds	2.52@2.64

The prices for Cardiff coal are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both net, and for cash in 30 days.

RUSSIA

The imports of coal into Russia during the first half of 1913 totaled 2,557,000 tons, as against 1,860,000 tons in the first half of 1912; coke imports amounted to 402,000 tons, as against 309,000 tons.

COAL SECURITIES

DIVIDENDS

Delaware, Lackawanna & Western—Regular quarterly dividend of 2½%, payable Jan. 20, to holders of record Jan. 3.

Lehigh Valley Coal Sales Co.—Regular quarterly dividend of $1.25, payable Jan. 20 to holders of record Jan. 2.

Lehigh & Wilkesbarre Coal Co.—Dividend of $3.25, payable Dec. 27 to holders of record Dec. 24.

Nova Scotia Steel & Coal, Ltd.—Regular quarterly of 1½% on the common and 2% on the preferred, payable Jan. 15 to holders of record Dec. 31.

Pittsburgh Coal Co.—Regular quarterly on the preferred of 1¼%, payable Jan. 2 to holders of record Jan. 15.

Island Creek Coal Co.—Earnings of this company in September of last year were at a rate which, if maintained throughout the year, would mean profits of about $900,000 after depreciation, or about $6 on the common stock after the regular 7% preferred had been paid.

Wilkes-Barre Colliery Co.—This company is issuing $500,000 first mortgage, 6% sinking fund gold bonds. Bonds are dated Sept. 1, 1912, and due Sept. 1, 1923, but are redeemable on any interest date at 102 and interest. Bonds are guaranteed by Madeira, Hill & Co.

Canadian Coal & Coke Co.—This company having $15,000,000 capital stock, and an authorized issue of $3,000,000 bonds, has taken over the Western Coal & Coke Co., Pacific Pass Coal Field, St. Albert Collieries, and the Lethbridge Colliery. It is said the new company will issue immediately $3,750,000 preferred stock, about $9,500,000 common stock, and $2,000,000 bonds.

Consolidation Coal Co.—The total assets of this company for the year of 1912 amounted to $62,965,467 as compared with $60,409,468 for the year previous. Capital assets for the same period were $49,274,181 and $46,400,867 respectively. The surplus last year amounted to $1,144,492 which was an increase of $962,171.

Bond County Coal Co. (Illinois)—The recent first mortgage issued by this company will be secured by 12,000 acres of thick vein Illinois coal owned in fee and estimated as containing 84,000,000 tons of recoverable coal. The bonds are guaranteed by the Peabody Coal Co., of New Jersey, which has a net paid in capital, surplus and reserve of $4,028,361.

The Reading Co.—Earnings of this company for October of last year amounted to $4,641,338 which is $148,268 or 3% less than the same period in 1912. This is accounted for by the unusual activity in the trade last fall due to the shortage of some 6,000,000 tons as a result of the suspension in mining early in the year.

Index of Current Coal Literature

We will furnish copy of any article (if in print) for the price quoted. Where no price is quoted, the cost is unknown. Inasmuch as the papers must be ordered from the publishers, there will be some delay for foreign papers. Remittance must be sent with order.

ACCIDENTS AND THEIR PREVENTION

Monthly Statement of Coal-Mine Fatalities in the United States, October, 1913; with Revised Figures for Preceding Months. Albert H. Fay. Bureau of Mines, 1913; 17 pp.

BLASTING, EXPLOSIVES

Method of Tamping for Greater Safety in Blasting. G. Volf. Coll. Engr., December, 1913; ⅓ p. 40c.

18 Fifty-Ton Railroad Cars Loaded In a Day With One Baldwin-Westinghouse BARSTEEL Electric Mine Locomotive

ground up.

MOTORMAN ESTABLISHES RECORD AT SCALP LEVEL

SPECIAL TO JOHNSTOWN DEMOCRAT.

SCALP LEVEL, Sept. 19—What is believed to be the highest record ever made in any section was made today in No. 1 mine of the Scalp Level Coal Mining company, one of the John Lochrie operations, when 18 steel cars were loaded by one motorman. The motorman who made the record output was Victor Gustasson. The foreman at No. 1 is William B. Wilson.

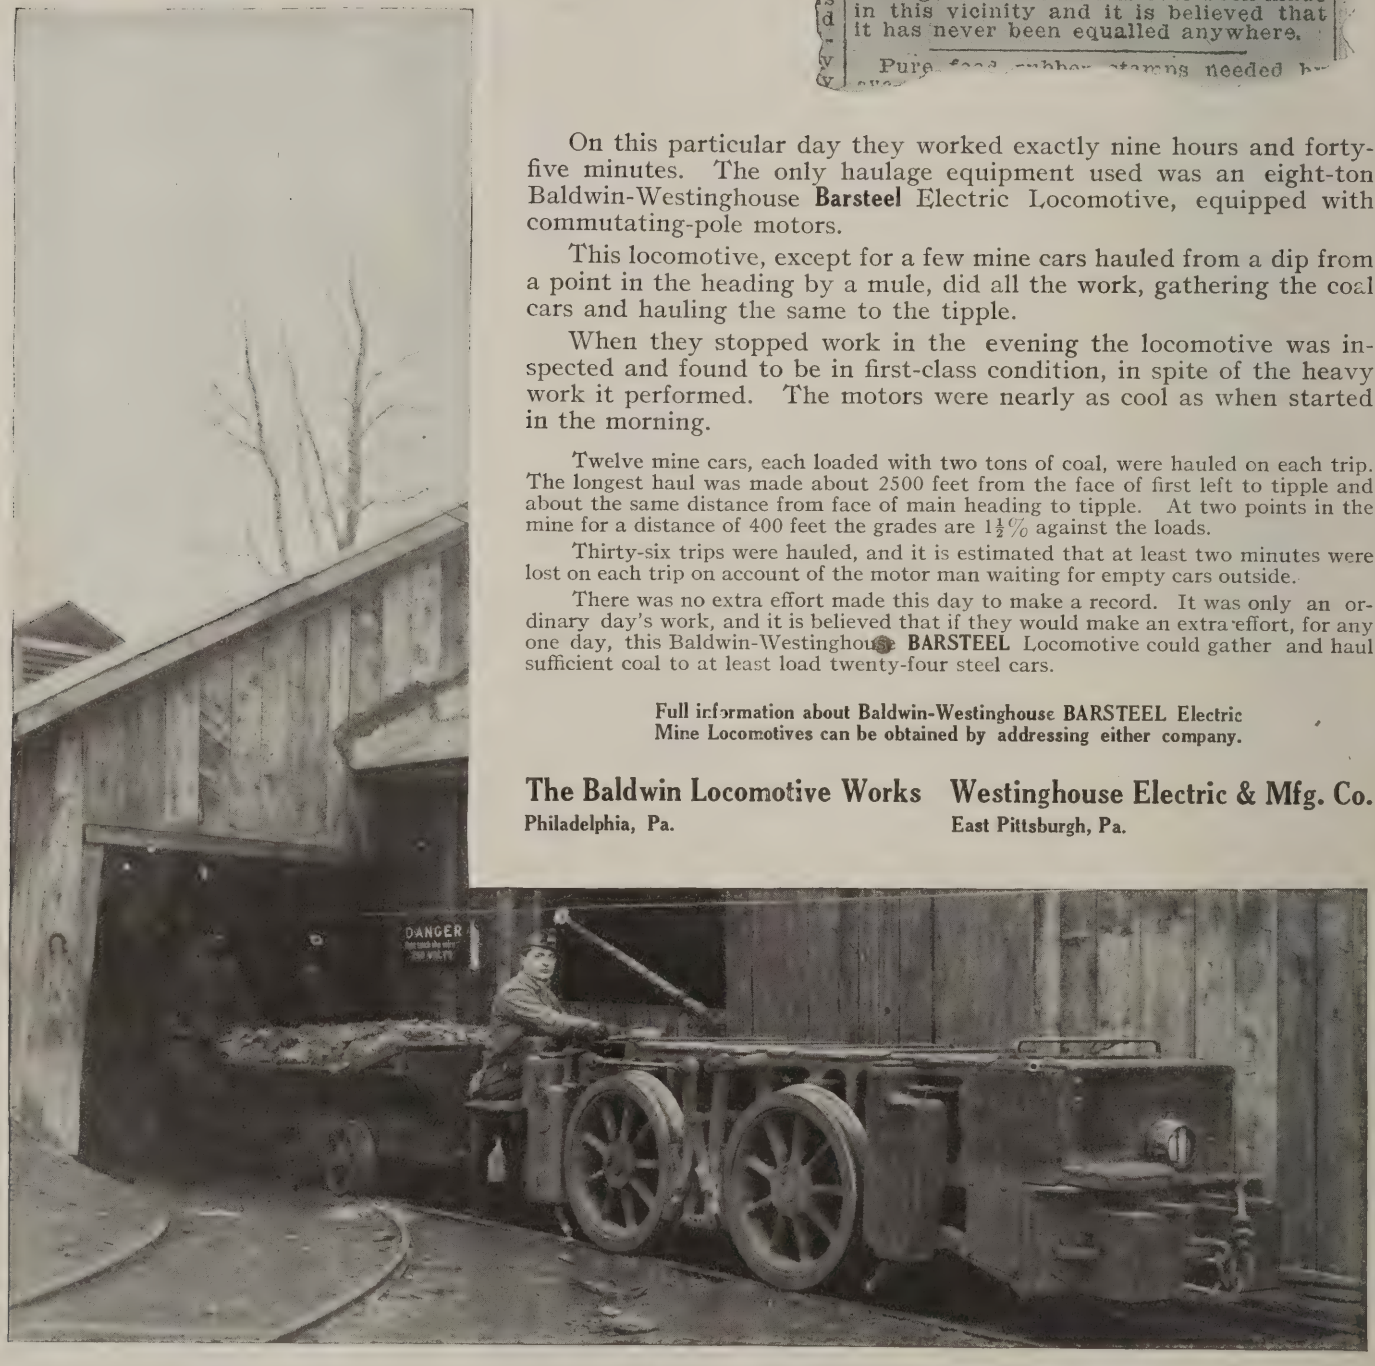
Eighteen steel cars of coal loaded in a single day with but one motorman is the highest run that has ever been made in this vicinity and it is believed that it has never been equalled anywhere.

On this particular day they worked exactly nine hours and forty-five minutes. The only haulage equipment used was an eight-ton Baldwin-Westinghouse **Barsteel** Electric Locomotive, equipped with commutating-pole motors.

This locomotive, except for a few mine cars hauled from a dip from a point in the heading by a mule, did all the work, gathering the coal cars and hauling the same to the tipple.

When they stopped work in the evening the locomotive was inspected and found to be in first-class condition, in spite of the heavy work it performed. The motors were nearly as cool as when started in the morning.

Twelve mine cars, each loaded with two tons of coal, were hauled on each trip. The longest haul was made about 2500 feet from the face of first left to tipple and about the same distance from face of main heading to tipple. At two points in the mine for a distance of 400 feet the grades are 1½% against the loads.



Thirty-six trips were hauled, and it is estimated that at least two minutes were lost on each trip on account of the motor man waiting for empty cars outside.

There was no extra effort made this day to make a record. It was only an ordinary day's work, and it is believed that if they would make an extra effort, for any one day, this Baldwin-Westinghouse **BARSTEEL** Locomotive could gather and haul sufficient coal to at least load twenty-four steel cars.

Full information about Baldwin-Westinghouse BARSTEEL Electric Mine Locomotives can be obtained by addressing either company.

CONTENTS

WITH PRINCIPAL ARTICLES SUMMARIZED

*Illustrated Article

FOREWORD: *Page* 43

Facts and Figures. A condensed review of the coal-mining industry for the year 1913, and some remarks concerning the future outlook. COAL AGE, Vol. 5.

REVIEW OF COAL MINING FOR 1913: *Pages* 44-64

Reports from mine inspectors and special correspondents in Alabama, Alaska, Arkansas, Colorado, Idaho, Illinois, Iowa, Indiana, Kansas, Kentucky, Maryland, Michigan, Missouri, Montana, North Dakota, Ohio, Oklahoma, Pennsylvania, South Dakota, Tennessee, Texas, Utah, Washington, West Virginia and Wyoming. Estimates of the year's production are given, with forecasts relative to probable business in 1914. COAL AGE, Vol. 5.

FOREIGN COAL PRODUCTION FOR 1913: *Pages* 65-68

Reports from mine inspectors and special correspondents in British Columbia, Saskatchewan and Nova Scotia. COAL AGE, Vol. 5.

PRESENT CONDITIONS IN COAL FIELDS OF MEXICO: *Pages* 68-69

Practically all the coal plants owned by Mexican capitalists were destroyed. Properties of American and English investors were not molested. If peace should be restored, the plants still standing will not be able to supply the demand of the country. COAL AGE, Vol. 5.

BUSINESS CONDITIONS AND THE NATIONAL COAL MARKETS IN 1913: *Pages* 70-74

Through a period of continued uncertainties in business, the coal markets developed an unexpected buoyancy and producers controlled the situation most of the time. A. T. Shurick. COAL AGE, Vol. 5.

REVIEW OF THE EXPORT TRADE IN 1913: *Pages* 75-76

More attention is being paid to the possibilities of foreign markets. American companies have had agents abroad surveying the ground. A number of fairly good contracts have been closed. American coal in South America. F. R. Wadleigh. COAL AGE, Vol. 5.

MARKETING AND SHIPPING CONDITIONS ON THE ATLANTIC COAST IN 1913: *Pages* 77-79

The year just closed was distinguished by the highest average prices that ever prevailed; $2.85 was the base price for Pocahontas, New River and Georges Creek. The sustained high level for the better Pennsylvania grades was a striking development of 1913. G. G. Wolkins. COAL AGE, Vol. 5.

NEW YORK MARKET EXPERIENCES A PERIOD OF UNUSUAL PROSPERITY: *Pages* 80-81

THE ANTHRACITE MARKET: *Pages* 81-82

CONNELLSVILLE COKE AND THE PITTSBURGH COAL MARKETS IN 1913: 82-85

A heavy Lake and manufacturing demand in the Pittsburgh region created an active coal market. Circular prices well maintained, with occasional premiums until the cessation of Lake shipping. B. E. V. Luty. COAL AGE, Vol. 5.

ANTHRACITE SHIPMENTS BY LAKE AND THE BUFFALO MARKET IN 1913: *Page* 85

Six Principles

The Weekly Ad-Talk Page

1. We believe the basic principle on which every trade paper should build is SERVICE—service to readers and service to advertisers, in a way to promote the welfare of the general public.

2. We believe in TRUTH as applied to the editorial, news and advertising columns.

3. We believe in CO-OPERATION with all those movements in the advertising, printing, publishing and merchandising fields which make for business and social betterment.

4. We believe that the best interests of manufacturers, the business press and consumers can be advanced through a greater interchange of facts regarding merchandise and merchandising, and to this end invite co-operation by manufacturers and consumers.

5. We believe in co-operating with all interests which are engaged in creative advertising work.

6. We believe that business papers can best serve their trades, industries or professions by being leaders of thought; by keeping their editorial columns independent of the counting room, unbiased and unafraid; by keeping their news columns free from paid reading notices and puffery of all kinds; by refusing to print any advertisement which is misleading, or which does not measure up to the highest standards of business integrity.

These are six out of ten "principles" as outlined by the Federation of Trade Press Associations in the United States in their eighth annual convention in New York.

Second the motion; we not only believe it—we're *doing* it. 'Nuff said!

COAL AGE

Vol. 5 NEW YORK, JANUARY 10, 1914 No. 2

Facts and Figures

The year 1913 was the greatest period ever experienced in the coal-mining industry. The output reached a total of 562,000,000 short tons which compares with a production of 534,000,000 tons in 1912.

Not only did the output exceed all previous records, but the value of the product at the mines was $753,000,000, an increase of 8.4 per cent. over the preceding year.

Bituminous production increased 22,000,000 tons, while the anthracite output was 5,600-000 greater than in the previous twelve months

Coke increased 2.8 million tons in output, reaching a total of 45,000,000. The value of this tonnage at the ovens was $135,000,000, an increase of 26 per cent. over the value of the 1912 production. Therefore in both quantity and price, coal and coke figures in 1913 established a new record.

The principal states to show increases in coal production were, Alabama, Illinois, Indiana, Kentucky, Ohio, Pennsylvania and West Virginia. Colorado showed a decrease in output caused by a serious strike that still exists in that state. Maryland also showed a small decrease due principally to some confusion resulting from recently enacted laws regulating child labor and providing for workmen's compensation. It is likely, however, that the Maryland field has reached its stage of maximum production.

The increased coke tonnage came principally from West Virginia and Alabama. The Pennsylvania output, although exceeding any previous year, was cut down by the slump that occurred in November and December. Alabama, also, would have made a better showing had it not been for the war in Mexico. This latter country is one of Alabama's best markets.

The most noteworthy event of the year in coal mining, was the national movement to reduce accidents and improve working conditions. Every manager, superintendent and foreman of any consequence, is striving to give his mine a clean slate in the matter of fatalities. Our greatest trust, the steel corporation, is without doubt the most ambitious aspirant for honors in the campaign for safety.

The outlook for 1914 in the coal industry would be better than any time in recent years were it not for the expiration of wage agreements in the bituminous field on April 1. The miners are instructing their delegates to insist on a "mine-run" basis, which demand the operators will surely refuse to consider. The action of the Ohio commission in approving the "mine-run" basis of payment will encourage the men and weaken the case of the owners.

Taking it all in all, the prospect for peace in the bituminous regions this spring is not favorable unless great forbearance is exercised by the two contending factions. The union in Central Pennsylvania has not relished the action of the operators in making public the frequent violations of the Scale Agreement by the men, and although the owners have temporarily insured better conditions by calling their employees to account, they have added fuel to the flames that may break out after April 1.

"It's an ill wind that blows no one good," and of course the anthracite mines and the West Virginia operations would profit by the misfortunes of the soft-coal owners in the unionized fields, should a lengthy suspension occur. However, it is best to remember that what hurts one part of the industry is also harmful to the business as a whole.

Let us all pray for peace in 1914. That accomplished, we will have the most prosperous year in history.

Reviews of Coal Mining for 1913

By B. M. Starnes*

Reports from state mine inspectors and special correspondents, giving estimates of the year's production and the outlook for 1914.

Alabama*

SYNOPSIS—Alabama coal production increased a million tons. Accidents materially reduced and but one explosion during the year. Trade and market conditions were exceptionally good. Car supply inadequate throughout the year. Water transportation from Alabama to the Gulf was opened and considerable new development carried through.

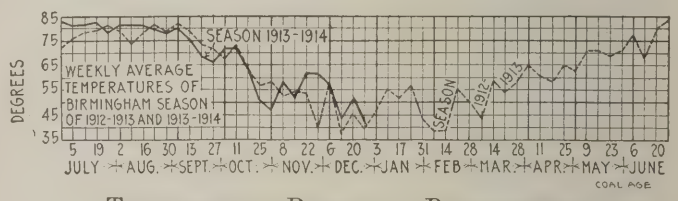
The coal mines of Alabama during 1913 produced 17,500,000 tons of coal, breaking all previous records by over a million tons of coal. Had the operators not been handicapped by a serious car shortage, and had business during the last two months held up the production would have been at least 18,500,000 tons, as it is estimated that a million tons were lost by these two causes alone. This will put Alabama in sixth place among coal-producing states of the Union.

Alabama has produced since 1870, which is as far back as the records go, the following tonnage of coal, coke and pig iron:

	Coal	Coke	Pig Iron
1870	13,200	.....	11,171*
1880	380,000	60,781	68,925
1890	4,090,409	1,072,942	816,911
1900	8,273,363	2,110,837	1,184,337
1910	16,139,228	3,231,399	1,939,141
1911	15,011,853	2,756,697	1,696,999
1912	16,513,040	2,881,861	1,832,146
1913†	17,500,000	3,500,000	2,018,343

* For 1872. † Estimated.

The number of nonfatal accidents in the Alabama mines during 1913 is approximately 133, which is about 15 per cent. less than in 1912. The fatal accidents for the year number 120, which is one less than the previous year. Below is a comparison of accidents in recent years:



Year	Fatal	Nonfatal	No. Employees per Life Lost	Tons per Life Lost
1900	37	13	386	223,603
1910	238	48	92	67,812
1911	209	90	108	71,827
1912	121	153	193	136,471
1913	120	133	206	147,060

There was only one mine explosion during the year, that at the Acton mine of the Alabama Fuel & Iron Co. in November, in which 24 men lost their lives. The Government has placed at the Birmingham rescue station the only automobile ambulance and rescue car in the Unietd States, and it has proved of great value in this work. Conditions at the mines for the safety of the men are improved vastly over last year, and the operators are giving more time and attention to "Safety First" than ever before.

Market Conditions

Steam and Domestic Coal—During the winter and early spring of 1913, the market on all grades of coal was exceedingly good, though lump coal was slightly under the average in tonnage due to a rather warm winter. The spring business beginning with Apr. 1 was excellent, the usual heavy tonnage of lump coal moving. The operators were looking for a rather quiet summer, but they were agreeably surprised, for 1913 will long be remembered as one of the best summers in the coal business in Alabama. Prices on all grades held up, and a heavy tonnage was moved. During the first six months over 10 million tons were handled. The great surprise of the year was the tendency of the market to lag during early fall, which is not usual in this district; it continued getting worse and worse, until there was practically no market whatever at the close of the year. Of course the usual contracts were made, but a large portion of Southern consumers prefer to buy on the open market as they need the coal, and it is this class of trade that seems to have dropped out of sight. The usual holiday-rush business failed to make its appearance, but the steam coals held their own in fair shape.

Blacksmith Coal—The producers of blacksmith coal enjoyed a good business, at prices from $2@2.25 per ton during the entire year. The tonnage was large during the winter and spring, falling off slightly in the summer, but recuperating as winter drew near. Prices have been about normal, and the operators are content.

Temperature Range at Birmingham

Furnace and Foundry Coke—The market on both furnace and foundry coke for 1913 has been a disappointment, for while the prices have held up well, the demand has been far under the expectations of the manufacturers. It is true that a larger tonnage was produced than ever before, but most of this increased tonnage went into the manufacture of iron by the makers themselves. The Mexican situation has cut Alabama from a profitable territory, as usually a large tonnage of coke is shipped to the Mexican smelters. The market conditions for the year could only be classed as fair.

Prices, Labor and Transportation Conditions

Below is a schedule of prices f.o.b. mines for the year on two of the standard lump coals of the district. Due to the unfavorable conditions, these prices have been cut materially during the latter part of 1913, though during the first nine months they were rigidly adhered to.

	Cahaba Lump[1]	Cahaba Nut[2]	Carbon Hill Lump[1]	Carbon Hill Nut[3]
January	$3.00	$2.50	$2.25	$1.90
February	3.00	2.50	2.25	1.90
March	2.50	2.00	1.75	1.45
April	2.50	2.00	1.75	1.45
May	2.60	2.10	1.85	1.55
June	2.70	2.20	1.90	1.60
July	2.80	2.30	1.95	1.65
August	2.90	2.40	2.00	1.70
September	3.00	2.50	2.15	1.75
October	3.00	2.50	2.25	1.95
November	3.25	2.75	2.25	1.90
December	3.25	2.75	2.25	1.90

[1] Over 6-in. screen. [2] From 3-in. to 6-in. [3] From 2-in. to 6-in.

Prices on Steam Coal—Approximate prices obtained on a few of the standard steam coals f.o.b. mines were:

*Sloss Sheffield Steel & Iron Co., American Trust Building, Birmingham, Ala.

Pratt run of mines	$1.25@ 1.45
Big seam run of mines	1.00@ 1.10
Cahaba run of mines	1.30@ 1.45
Black Creek run of mines	1.35@ 1.50
Washed slack	1.20@ 1.30
Unwashed slack	0.30@ 0.60

Blacksmith Coal and Coke f.o.b. mines were about as follows:

Blacksmith coal	$2.00@ 2.25
Furnace coke	2.75@ 3.50
Foundry coke	3.50@ 4.25
Coke breeze	1.50@ 2.00

Car Supply—This district has suffered severely from a serious car shortage during the entire year. Even during the summer months, the railroads were not able to supply sufficient equipment to enable the operators to run regularly; in some cases the mines worked only from one-third to one-half time. The dull market during the last three months has aided the roads in this respect, but, should the usual winter trade develope after the halidays, the railroads will not be able to cope with the situation. It is estimated by the coal operators of this district that the production was restricted by over 500,000 tons by the lack of cars.

Labor Situation—Alabama has had no labor troubles this year. Many of the large operators have voluntarily

Charles H. Nesbitt, Alabama

increased wages to all employees, and, as the mines have been almost constantly at work, it has kept the labor in this district well satisfied.

Water Transportation—The dream of the coal operators in this district—water transportation from Birmingham to the Gulf—has at last come true. The Alabama & New Orleans Transportation Co. is now operating barges from Tuscaloosa, Ala., down the Warrior River to Mobile and New Orleans. While it has not yet proved a decided success, owing to the low water and the unfinished lock, still, within the next year, Alabama will see at least 500,000 tons of coal barged to the Gulf, at a much lower cost than by rail.

Improvements

Some of the principal improvements by coal companies during the past year are as follows:

Central Iron & Coal Co., at Holt, constructed 40 byproduct coke ovens, of the Semet-Solvay type.

Alabama Co. reopened its Searles mines, which had been closed down for about a year. They are now operating on a capacity of 1000 tons per day.

American Steel & Wire Co.'s wire and nail mill, at Fairfield, put into operation.

Tennessee Coal, Iron & R.R. Co. announced that it would build a new furnace and steel converter at Ensley, at a cost of $200,000.

Sloss Sheffield Steel & Iron Co. relined the Philadelphia furnace, Florence, Ala.

United States Steel Corporation announces that it will build an ore-unloading plant at Mobile, at a cost of $800,000 to receive its Cuban ores.

Sloss Sheffield Steel & Iron Co. opened nine new mines at Drifton, Brookside, Dora, Cardiff and Blossburg.

Pratt Consolidated Coal Co. built a new washer and tipple at the Banner mines, concrete and steel structure.

Sloss Sheffield Steel & Iron Co. opened nine new mines at Top.

Tennesee Coal, Iron & R.R. Co. opened up its Bay View mine and announced that they would open up a new mine at Bloston on the Woodstock seam.

Bessemer Coal & Iron Co. installed a new washer at Aldrich, Ala.

Red Eagle Coal Co. opened up a new mine at Bloston.

American Coal Corporation developed its Beltona mines near Warrior, Ala., at an expenditure of $400,000. Now operating and getting out 600 tons per day.

Alabama Consolidated Coal & Iron Co. properties transferred to the Alabama company.

Southern Iron & Steel Co. sold to the Gulf States Steel Co.

G. B. McCormack and Erskine Ramsay announce that they would build a battery of byproduct coke ovens with a capacity of 1500 tons of coke daily.

Sloss Sheffield Steel & Iron Co. announce it will build a battery of 300 beehive ovens at Bessie.

Bessemer Coal & Land Co. purchased the properties of the Montevallo Mining Co.

Yolande Coal & Coke Co. purchased the Abernant Coal Co.

Bessemer Coal, Iron & Land Co. purchased 40,000 acres of land in Fayette County, said to contain a high-grade coal.

Pierce Coal & Lumber Co. developing 20,000 acres of coal lands in Jackson County.

Panama Coal Co. announced that it would develop 15,000 acres of coal lands in the Sipsey Valley.

Alabama Fuel & Iron Co. opened up its No. 4 Marguerite mine at Marguerite.

Central Cahaba Coal Co. opened up a new mine at West Blocton.

'Frisco R.R. built a 12-mile spur, tapping the coal fields of Walker County, known as Sipsey Valley, thus opening up a large territory rich in coal.

New Incorporations

The following are the principal new incorporations during the year:

C. B. Stalnacker and associates, of Jasper, developing a tract containing a 9-ft. seam near Jasper.

Gas Light Coal & Coke Co. To develop 2000 acres of coal at Dulin.

West Pratt Coal Co. Capital, $100,000. John Armstead, president. To develop coal lands at Dora.

Morris Coal Co. W. F. Francis, president. To develop 2000 acres near Morris.

Little River Mining Co. To develop 7500 acres in north Alabama.

Maryland Coal & Coke Co. To develop 15,000 acres of coal lands in the Sipsey Valley. Now operating and getting out 800 tons per day Black Creek coal.

Eureka Coal Co. To develop tract of coal land at Fallis-ton.

Blount Mountain Coal & Lime Co. To develop tract of land in Blount County.

Nunley Ridge Coal Co. Capital, $24,000. R. D. Curry, president.

General Notes

The Acmar mine, of the Alabama Fuel & Iron Co., will lead the mines of this state in tonnage for 1913 with

approximately 460,000 tons. The Sayreton mine of the Republic Iron & Steel Co. will follow with an output of approximately 440,000 tons. It is estimated that there are 24,014 miners in Alabama.

It is rumored that the Southern Ry. is to purchase the Gulf, Florida & Alabama R.R., which owns extensive terminals in Pensacola, Fla. This line is building from Pensacola to Jasper, Ala., the center of the coal fields, at which point it will connect with the Southern, and thus give the latter a direct connection with the export trade at Pensacola.

It is also rumored that the Central of Georgia will build through Milton, Fla., to Pensacola, and, as this road is owned by the Illinois Central, which penetrates the coal district of Alabama, Pensacola will thus have another coal railroad; at the present time, the only line into Pensacola by which coal can be shipped is the Louisville & Nashville. With three roads, Pensacola would be a great bunkering point on the Gulf.

Alaska

Sumner S. Smith, U. S. mine inspector for Alaska, reports to us that mines are few in that territory, and only a small tonnage of coal has ever been produced.

"During the past season," he says, "some 1600 tons were mined from the Wharf property, near Seldovia, on the south coast of Kachemak Bay of the Kenai Peninsula. The coal is lignitic. A few tons may have been mined on Chicago Creek, near Candle, but Mr. Smith is not certain. Candle is located on the west coast of Alaska a halt a degree south of the Arctic Circle, on Kotzebue Sound.

Eight hundred tons, as will be seen in another part of this issue, were produced for the use of the navy on the Chickaloon River, a branch of the Matanuska.

This tonnage, however, is doubtless yet at the mine and it is questionable whether the weather conditions will permit it to be shipped to tidewater this winter.

Arkansas

By Thomas H. Shaw*

SYNOPSIS—The coal in Arkansas is of excellent quality and sells for a good price. Its presence has been known since 1818. The labor situation in 1913 has been complicated by a disagreement over the interpretation of a contract signed with the union.

In reviewing the coal-mining industry of Arkansas for 1913, it will not be possible for me to give the exact figures as to coal production, number of employees, number of days worked, etc., for the calendar year ending Dec. 31, 1913. This is due to the fact that the state law requires all statistical data relating to the coal-mining industry to be collected for the fiscal year ending June 30.

The area of the coal regions is about 2000 square miles, comprising six counties, viz.: Sebastian, Scott, Franklin, Johnson, Logan and Pope. The counties producing the largest amount of coal are Sebastian, Franklin and Johnson.

Early Mining History

Coal in this state was given its first written notice in 1818. The first opening deserving mention was the old Spadra mine, located at the mouth of Spadra Creek, in Johnson County, where a steam plant was in operation about the year 1870. Mining was carried on at Ouita in Pope County in 1873. About this date, country banks were opened on Massard prairie not far from Fort Smith and on Long prairie near Jenny Lind, which produced collectively about 8000 tons per annum and which was hauled to Fort Smith in wagons. About the year 1887 the Western Coal & Mining Co. and the Kansas & Texas Coal Co. commenced extensive mining operations at Jenny Lind, Hackett and Huntington. The production increased to 1,900,000 tons per annum from 1900 to 1906.

Production of Fiscal Year

The production reported for the fiscal year ending June 30, 1913, was 1,952,461.93 tons, which was produced by 4188 miners, 316 mules and 77,785 kegs of black powder. Five companies did not report. They employ about 300 men. I estimate their tonnage at about

Thomas H. Shaw, Arkansas

200,000 tons per annum, which would make the total 2,152,461.93 tons. I believe that it will be safe to say that the production for the calendar year will exceed 2,250,000 tons. Five of the largest mines in Sebastian County have installed electric coal-mining machines which are proving to be a success in two ways: First, in safe-guarding the shotfirers and property from explosions, which are frequent in these mines when the coal is shot off the solid; second, in making a better quality of coal.

A new mine at Hartman, Johnson County, and another at Alix, in the same county, will be ready to ship coal in the near future. Pope and Johnson Counties have a fine quality of semi-anthracite coal second to none in the entire Southland; it is free burning, producing a uniform heat, does not clinker, and is an excellent stocker; the average selling price, f.o.b. mine, is about $3 per ton. The mining of coal will make a manufacturing city of Fort Smith, the county seat which is surrounded by cheap coal, and has six railroads entering into it.

During the last year there have been many local strikes caused by a difference of opinion as to the construction

*State mine inspector, Midland, Ark.

to be placed on the agreement between the miners and operators. The mine of the Scranton Anthracite Coal Co., at Montana, Johnson County, is still idle over a strike that commenced on Sept. 5. Six fatal and 25 nonfatal accidents occurred during the fiscal year.

There have been numerous minor explosions in the mines of Arkansas during the past 20 years, of which no official record has ever been made. It is of interest to note the two largest accidents which have occurred in the mines of this state, namely, that at Huntington in 1897 and that at Bonanza in 1903. On Mar. 4, 1897, in the Kansas & Texas Mine No. 44 at Huntington, Ark., a powder and dust explosion occurred, in which 14 men were killed and 12 badly burned. On Nov. 20, 1903, in the Bonanza No. 20 mine at Bonanza, Ark., a gas explosion occurred in which 11 men were killed and two escaped, both badly burned.†

Colorado

By A. R. Tibbitts*

SYNOPSIS—The production of coal has been considerably affected by a strike which commenced in the northern field in 1909, and which was ineffective but never declared at an end. The southern field was unionized and a strike was declared on Sept. 23, which is likely to last some time. The strike occurred in face of large concessions in wages to day men.

With the closing of the year 1913, the coal industry of Colorado is seriously hampered by a bitter coal strike. Furthermore, there are no prospects of a settlement in the near future. Both parties to the dispute are determined not to concede the one vital point on which the strike hinges, namely, recognition of the union.

In the early months of the year, during the session of the last legislature, a new coal-mining bill was submitted for passage and was referred for a revision to a subcommittee, composed of two operators, one representing the Colorado Fuel & Iron Co., the other the Rocky Mountain Fuel Co., two coal miners, one the state inspector of coal mines and the other a member of the international board of the United Mine Workers of America, representing District No. 15, and the fifth member, an acting state senator and a metal miner by calling, who was the chairman of the committee.

A Drastic Law Which Met with Ready Compliance

The result was a strong and effective law, in the modeling of which, for the first time in the history of Colorado, laborer and employer were in harmony. The law as revised received the approval of all the operators and the mine workers. This law went into effect on Apr. 5, and gave the operators six months to comply with its provisions. The result was gratifying. Immediately the coal companies, especially the large ones, proceeded to carry out the numerous improvements demanded by the act which in most cases meant the outlay of much money, and in all cases, compliance with its new requirements increased the cost of production.

One of the great contentions had been the nonemployment of check weighmen at the various mines. The miners were allowed, without any protest or delay, to avail themselves of the provision in the new law permitting them to select their own check weighmen.

Concessions to Miners

An eight-hour law had been passed by the 19th general assembly, and before it went into effect, most of the large companies placed their mines on its basis with pay for a 10-hour day. In addition to these concessions, in the northern field, where the strike called in 1909 is still in progress, the operators on Oct. 15 of this year, granted a further increase in the wage scale to the underground workers amounting to 6 per cent.

However, with the beginning of the year, each month showed a decrease in the production of coal, the cause of which was laid to shortage of men. In July the production took an upward turn until the strike was called. Under normal conditions the production would probably have been about the same as in 1912, to wit, 11,016,948 tons. Conditions were improving at all the mines, the wage scale seemed satisfactory and there was no special indications of unrest.

Beginning of Strike

The strike that had been called in the northern field in April, 1909, and is still in force, resulted from a disagreement as to the wage scale. However, nonunion miners took the places of the strikers, and while production was not and has not resumed its normal capacity, yet it was sufficient to meet the demand of the market. The Moffat R.R. bringing to Denver large shipments of Routt County coal, no doubt lessened the demand for lignite, as the former coal is considered a splendid fuel for all purposes.

The United Mine Workers, it would seem, have not been idly waiting for the settlement of this older strike, but had a number of their organizers out in the southern field and an effective unionizing of the men was accomplished as results show.

In September a conference was called by the leaders of the union but was ignored by the operators, not one responding, and on Sept. 23 a strike was called, and about 85 per cent. of the men came out. In consequence, the production in October was over a half million less than in September, that month holding its own, as great activity was displayed at the mines in anticipation of the coming strike.

The November and December output will show the same decrease. Several sincere attempts have been made to effect a settlement but they failed. The operators are willing to grant open shop, to abolish compulsory trading at their company stores, to carry out all the provisions of the new law, but they absolutely refuse to recognize the union as a body. The men as stubbornly will not waive this one demand. Some of the operators of small mines have signed up with the union and are getting out increased tonnages.

The militia was called out to maintain order and allow such men as wished to return to the mines to work unmolested, but notwithstanding there is very little change in the situation.

High Price of Coal Creates Unfavorable Criticism

Shortly after the strike was called, the market price of coal went up as high as $7.25 for bituminous and $6.50 for lignite lump coal per ton. Whether there was more

†Neither of these is recorded in the remarkably complete list compiled by the Bureau of Mines.—Ed.

*State inspector of coal mines, Denver, Colo.

coal stored than was known, or the consumption of coal was curtailed by the warm weather prevailing in October and November, the prices have dropped 25 and 50c. per ton.

Several of the large coal companies are operating state land and as their production is affected by the strike and the prospects of a settlement are not encouraging, there is much agitation in favor of the state of Colorado operating the mines on its own land. However, as this would be a radical experiment with uncertain consequences, it is not likely to be put into effect; the advocacy of such a move probably being nothing more than a resentful protest against the increased cost of fuel and the loss and demoralization of all business that a strike of such proportions as this is bound to entail.

The new law imposed a tax of $\frac{1}{2}$c. per ton on run-of-mine, payable quarterly, and creates a coal-mine inspection fund. Two quarters have elapsed and there has been no trouble in the collection of this tax and no question of legality raised to evade payment.

COAL PRODUCTION OF COLORADO FOR THE YEAR 1913

Number of mines in operation		167
Tons of lignite coal produced	1,513,528	
Tons of semibituminous coal produced	824,549	
Tons of bituminous coal produced	6,850,355	
Tons of anthracite coal produced	51,903	
Total number of tons produced	9,240,335	
Total number of tons produced in 1912	11,016,948	
Total number of tons of coke produced		889,989
Total number of employees in and about the mines		13,107.6
Total number of days worked		191.2
Number of men killed in the mines (38 killed in the Vulcan disaster.)		111

PRODUCTION BY COUNTIES

Boulder	968,018	Jefferson	154,531
Delta	79,005	Las Animas	3,781,713
El Paso	329,054	La Plata	138,414
Fremont	536,793	Mesa	123,876
Garfield	159,589	Pitkin	52,048
Gunnison	474,469	Routt	304,737
Huerfano	1,647,368	Weld	428,795
Jackson	61,925		
		Total	9,240,335

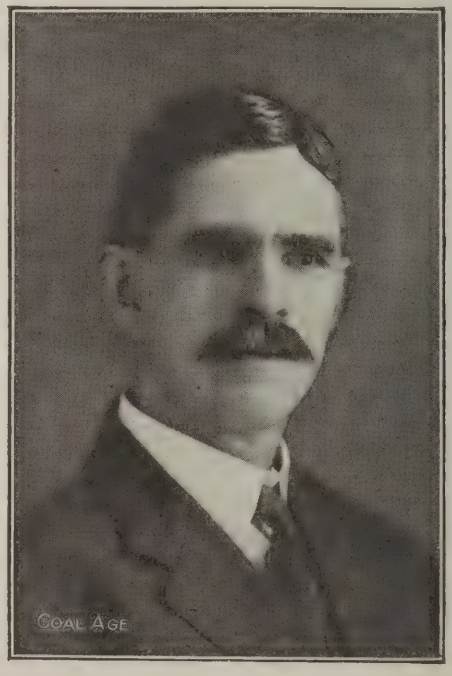
December output (estimated) 608,898 tons.

Idaho

By Robert N. Bell*

SYNOPSIS—The state only produced about 2000 tons in 1913. The Interior Department has recently permitted entry on coal lands and some progress in development may be expected.

The coal-mining industry of Idaho is in an embryonic stage as the state is almost exclusively occupied by crystalline metal-bearing formations. We import and use annually from the neighboring states of Wyoming and Utah and from British Columbia approximately two million tons of coal and produce from Idaho sources a negligible quantity of about 2000 tons, which has been the annual output for the past 7 or 8 years.



Our metal mines employ over 6000 men and their principal product is lead-silver ore. We excel every other state in the Union in the output of this class of mineral, but our possible coal-bearing formations are limited indeed and consist of a small area embracing only a few townships on the eastern border of the state in Fremont County, where a portion of the rich coal-bearing Laramie Cretaceous horizon extends over the Idaho line from Uintah County, Wyoming, and in which there has been discovered a series of 18 closely parallel and steeply pitching seams of high-grade soft coal.

This coal, like many other Western fuels, is classified as black lignite, but as a matter of fact is of excellent quality and high heating value with a long flame and equal to some of the best Eastern bituminous coals in steam-producing and storage qualities.

Until a year ago, when a new railway branch was completed within 10 miles of the mines, these deposits were situated nearly 35 miles from the nearest transportation point, and all the coal mined in their development has been sold to the local farming community of the Upper Snake River plains which is a well populated irrigated- and dry-farm territory. The trade with the farmers occurs when sleighing is good, the coal being sold them at the mine at prices ranging from 50c. per ton for slack to $3.50 per ton for clean lump coal.

A Reason for Idaho's Backwardness

The tardiness of the development of this promising series of coal deposits is accounted for by the fact that they are owned by local Idaho people of small means, and have been situated until a year ago on unsurveyed public land, which, since the discovery of the coal, has been withdrawn as forest reserve, phosphate-rock reserve and for coal classification.

Robt. N. Bell, Idaho

This has made the process of obtaining title from the government difficult, but the present administration of the Interior Department has taken a broader view of the matter and has restored to entry the two sections of land covering the principal development. Final certificate for patent has been issued on these two claims, and with the completion of title, it is likely that these deposits will be more extensively developed as there is a crying demand by the settlers in this locality for cheaper fuel. Soft coal from Wyoming and Utah brings from $8.50 to $10 per ton at the railroad siding and we are living in hope that Idaho will make a little better showing in the coal-production list of the United States is the not distant future.

*State mine inspector, Boise, Idaho.

Note—For lack of space, this interesting report has been curtailed and will be completed in a forthcoming number.

Illinois

By Martin Bolt*

SYNOPSIS—A substantial advance has been made in coal mining during the past two years. No serious labor troubles have been experienced although there have been many petty suspensions. The fatal mining accidents are estimated at 180 for the year, six large new mines have been sunk and the tendency in practice is away from the mine of small production.

Coal mining in Illinois has been making a steady, substantial advance for the fiscal years, ending June 30, 1912 and 1913. The number of short tons mined for the above periods was for the year ended June 30, 1912, 57,514,240, and for that ended June 30, 1913, 61,846,204.

The output of the shipping mines, for the same years, was: June 30, 1912, 56,096,696; June 30, 1913, 60,616,416. These figures show an increase of 4,519,720 tons.

From Jan. 1, 1912, to June 30, 1912, the shipping mines produced 26,574,232 tons; from July 1, 1912, to Dec. 31, 1912, 32,494,086 tons.

Figures at hand at the present time will show that the commercial or shipping mines produced in the calendar

Martin Bolt, Illinois

year 1912 in round numbers 59,000,000 short tons, and from the same source we find that the tonnage during the first half of the year 1913 from the same mines was 28,621,330 tons. Assuming that the same relative increase is maintained the approximate tonnage for the calendar year ending Dec. 31, 1913, will be 62,000,000 short tons.

There is a possibility, however, that the mild weather for the past few weeks will reduce the figures slightly, but not to any great extent.

There has been no serious labor trouble in the mines of Illinois in the year 1913, although there have been a large number of temporary suspensions of single mines. These troubles, while much to be regretted, do not materially affect the total output.

Accidents in the mines of the state heretofore have increased at about the same rate as the tonnage. The number of fatal accidents for 1913, based on former years and figures at hand, will probably be nearly 180 and may be in excess of this number, the estimate for 11 months ending Nov. 30, 1913, is 163.

The fatal accidents in the shipping mines for the years ending June 30, 1912 and 1913, are the same for both years, namely, 173; the nonfatal accidents for the same years are as follows: 1912, 792; 1913, 1016, or an increase of 28.28 per cent. As the figures for the fiscal and calendar years vary only slightly, it is fair to assume that the fatal accidents for the calendar year 1913 will be about what they were for 1912, while the nonfatal accidents will show an increase of nearly 28 per cent.

The number of shipping mines will show a slight decrease, but the average production per shipping mine will show an increase.

There have been six large mines opened in this state during the year, as follows: Franklin County has three and all will be large producers of coal. Christian County has two, the Illinois Midland Coal Co.'s Nos. 7 and 8, located at Kincaid, on the Illinois Midland R.R., seven miles from Taylorville. The Nokomis Coal Co. has also put down a large mine at Nokomis, in Montgomery County. All of the foregoing are in the No. 6 seam, while Newsam Bros. have a new mine at Glasford in Peoria County, which is down to the No. 5 seam.

*Chief clerk, State Mining Board, Springfield, Ill.

Iowa

By L. E. Stamm*

SYNOPSIS—The conditions governing the mining industry of Iowa during 1913 were not materially different from those existing in 1912. The production for the fiscal year ending June 30, 1913, was over 7,400,000 tons, and it is confidently believed that the output for the calendar year 1913 will not vary greatly from that of the fiscal year.

The general conditions of the coal industry in Iowa for the year 1913 were very similar to those existing in 1912. Progress in the mines of the state has been, on the whole, fairly satisfactory during most of the year. However, weather conditions in the months of October, November and December were such that there was a general falling off in the demand for coal of all grades. With the exception, therefore, of the large operations having railroad contracts, the mines of the state did not work up to their capacity during the months named above.

Statistics covering the coal production of Iowa are gathered by the mine inspectors' department for the fiscal year ending with June 30 of each year. Those secured for the year 1913 show an increase of 594,929 tons over the amount produced in the state of 1912. The production for 1913 by districts with the number of miners employed in each is as follows:

COAL PRODUCTION OF IOWA FOR FISCAL YEAR 1913.

	Tons of Coal.	Miners employed
First District	2,813,789	6,345
Second District	2,337,708	4,777
Third District	2,264,260	4,563
Total	7,415,757 Tons	15,685 Employes
Coal Production for year ended June 30, 1912	6,820,828	
Coal Production for year ended June 30, 1913	7,415,757	
Gain for 1913	594,929 Tons	
Fatal Accidents for the year 1913	24	
Non Fatal Accidents for the year 1913	176	

*Secretary Iowa Mine Inspectors, Des Moines, Iowa.

Twenty-three counties in the state are listed as coal-producing. In a number of these the mining operations are conducted on a small scale and the few mines that are operating are worked only in the winter to supply the local trade. Monroe County is the largest producer of coal of all grades. Polk County ranks second and Appanosse third. Last year these three counties yielded 5,243,279 tons of coal, or more than two-thirds of all that produced in the state.

New developments in the coal industry are in progress in several of the larger counties in the state, and the mines now started will be in shape to add considerably to the output for the coming year. Some new developments have also been made in Polk County the past year, and all these point to an increase in the coal production of the state for the coming year.

Iowa had fewer fatal accidents in the mines for the fiscal year of 1913 than for many years. The number of tons of coal mined for each fatal accident was much higher than in former years. The number of nonfatal accidents for 1913 was about the same as for 1912. The majority of the accidents occurring in the mines were caused by falls of roof or slate. These were for the most part in the rooms of the miners with but few on the entries.

The next greatest cause of accidents was that of being struck by cars, falling off cars, etc. These occurred chiefly to the drivers in the mine. There were no accidents of great magnitude in the mines during the year, and none in which more than one person met death at once. Iowa will, therefore, compare favorably with any coal-producing state in the Union with respect to accidents, both fatal and nonfatal.

Both the operators and the miners of this state have an organization and a working agreement is entered into every two years by the representatives of these bodies. Therefore, but few labor troubles occur in the mining industry. Those that do take place are chiefly local and last but a few days, the trouble usually occurring over the interpretation of the working or wage agreement. These are generally settled quickly by the representatives of both organizations.

Considerable improvements have been made in the mines of Iowa during the past year, chiefly in the manner of transporting the coal in the mines. Many operations have installed gasoline motors, others use electrical haulage. Some of the mines of the state are equipped with eletrical hoists. Mining machins have also been introduced in some of the mines, and the general tendency is toward lessening the cost of production by better equipment for handling the product.

In conclusion, it may be said that the total production of coal in Iowa for the fiscal year ending with June 30, 1913, was 7,415,757 tons. It is firmly believed that the production for the calendar year 1913 will approximate that of the fiscal year.

Indiana

By F. I. Pearce*

SYNOPSIS—The coal production of Indiana for the fiscal year ending Sept. 30, 1913 is reported as over 17 million tons. The total number of men employed was 21,683 and the average yearly wage was $736.06. There were in all 59 fatalities in and about the mines of the state.

If the number of tons of coal produced and wages paid mine employees is any criterion, the mining industry of Indiana, as a whole, for the fiscal year ending Sept. 30, 1913, discloses a fairly gratifying condition of both miners and mine operators. Notwithstanding the fact that there were a few operations closed down the entire year and practically all of them lost either a few days, weeks or months time on account of no sale, lack of railroad cars, local strikes or other causes, the production is reported as 17,246,565 short tons, or 877,679 tons less than the largest and 3,041,987 tons more than the second largest production in the history of the state.

Of this production, 9,637,901 tons or a fraction less than 56 per cent. was mined with machines, and 7,608,664 tons or 44 per cent. by hand. This, shows an increase of about four per cent., in the production of coal mined by machines over that of last year. And this production would have been even larger had it not been for the difficulty experienced in undercutting the coal in a number of mines in which mining machines were tried out.

In producing this coal there were used, 526,580 kegs of black powder, 283 cases of "permissable explosives" and 52 cases of Hoynsite safety powder.

While it is true that considerable time was lost at some of the mines on account of causes other than those due to shortage of railroad cars, local strikes and the flood in March, yet the major part of the time lost may be attributed to dull trade, resulting from an open winter, an increased production and extremely sharp competition in securing a market.

The following table exhibits the relative rank of the twelve counties in the number of tons produced and wages paid:

TABLE SHOWING THE TONS OF COAL PRODUCED AND WAGES PAID TO MINERS IN INDIANA FOR THE YEAR ENDING SEPT. 30, 1913 BY COUNTIES—THE BLOCK AND BITUMINOUS COAL EACH BEING SHOWN SEPARATELY

County	Production of Block Coal	Wages Paid	Production of Bituminous Coal	Wages Paid	Total Production	Total Wages
Vigo	109,380	$67,875.12	4,367,565	$4,033,962.91	4,476,945	$4,201,838.03

Total	445,585	$673,272.66	16,800,980	$15,286,724.97	17,246,565	$15,959,997.63

Vigo County, due to the increase of development in that field recently, exceeded Sullivan as the largest producing county in the state by more than 1,238,303 tons.

Distribution of Product

Of the bituminous coal, 10,078,336 tons were consumed in Indiana, and 6,722,644 tons were shipped to other states. Of the block coal, 203,522 tons were consumed in Indiana and 242,063 tons were shipped outside, or a fraction less than sixty per cent. of the total production was consumed within the state. This shows an increase of about two per cent. in the home consumption of the yearly production over that of any previous year, indicating that the consumers of coal are beginning to realize more than ever, the value of Indiana fuel.

Cost of Production

The total wages reported from the bituminous field was $15,286,724.97, making a fraction less than 91 cents

Frank I. Pearce, Indiana

per ton for the labor cost of production. The total wages reported from the block coal field was $673,272.66 or a fraction over $1.51 per ton for the labor cost of production. These figures show a slight increase in the cost per ton for the labor for the total production of bituminous and block coal over that of any previous year.

Besides the many varying conditions to be met and overcome in the operation of a mine that result in a variation of the cost of producing a ton of coal, one year with another, there are many things which now contribute to increase the cost, and to that extent necessarily add to the selling price. Higher wages are an important factor; deeper mining and the increased expense of keeping the mines in proper condition, more efficient safety appliances to protect life and health, the rising cost of timber and all kinds of material used in a mine contribute to increase the cost of production.

Market Prices

The market price for mine-run bituminous coal (except yearly contracts), f.o.b. cars at the mine, during the period from Oct. 1 to Dec. 31, 1912, ranged from $1.15@1.45 per ton; from Jan. 1 to Mar. 31, 1912 from $1.05@1.25 per ton; Apr. 1 to June 30 from $1.05 (with perhaps some selling as low as $1) @ $1.20; from July 1 to Sept. 30, the selling price ranged from $1.10@1.15 per ton. The market selling price for screened block coal, (except yearly contracts), f.o.b. cars at the mine, from Oct. 1 to Dec. 31, 1912 ranged from $2.10@2.50; from Jan. 1 to Mar. 31, 1913, the price averaged about $2.20; Apr. 1 to June 30 from $2@2.10 and from July 1 to Sept. 30, the price ranged from $2.10@2.20.

The total number of employees reported for the year was 21,683, or an increase of 453 over the last year. Of this number 20,441 were bituminous, and 1242 block mine employees.

The aggregate number of days the mines were reported as being in operation was 29,452, and the number of days idle, due to no sales, 10,408; no railroad cars, 2195; local strikes, 273 and on account of funerals, 35; others causes, 3353.

Average Wages

The total wages reported from the bituminous field being $15,286,724.97 makes an average earning of $747.84 for each bituminous employee. The total wages paid to block coal mine employees being $673,272.66 shows an average earning of $542.08. The aggregate wages for the state being $15,959,997.63 and the total number of employees, 21,683 shows an average earning of $736.06 for each mine employee in the state, which is the highest average wage earned per mine employee.

New and Abandoned Mines

Sixteen new mines, all of which, with the exception of two or three will be large producers were opened up, and eleven mines were abandoned during the year ending Sept. 30, 1913.

Fatalities

During the year there were 59 fatalities. The most prolific causes of accidents were the following: Falling slate at the face, 18; use of explosives, (including firing of shots) 15; mine cars and motors, 7; explosions of firedamp, 6; falling coal at the face, 4; falling slate on the traveling and roadways, 4; in all 54 or 93 per cent. of the total number of fatal accidents, may be attributed to these causes.

Of the six fatal accidents due to explosions of firedamp, three were caused by a suddent liberation of gas following the caving in of the roof and three to firedamp that had accumulated in the mine as a result of booster fans (operated by electric power) which have recently come into use in mines of this state, being allowed to stand idle.

The above data do not include figures for about 450 small mines, clay and strip banks which have an estimated production of about 450,000 tons employing from 2500 to 3000 men since these do not come under the jurisdiction of the mine-inspecting department.

Kansas

By Francis Keegan*

SYNOPSIS—The estimated production for 1913 is placed at 7,400,000 tons. This output, which is a decided increase over previous years, has been accomplished with a decrease in fatalities. The steam shovel is beginning to play an important part in the stripping operations in the Kansas field.

The records in the office of the State Inspector of Mines for Kansas, when completed, will show that in

*Assistant commissioner of labor, Pittsburg, Kan.

round numbers 7,000,000 tons of coal were produced during the fiscal year ended June 30, 1913. Basing estimates on the figures for this period, which shows a marked increase in production over former years, there is every reason to believe that the calendar year 1913, will prove to be the most prosperous in the coal-mining industry in the state's history in point of tons of coal produced, number of men employed and number of days worked. In fact there is no hesitancy in saying that a conservative estimate of the production of coal from the mines, including the strip pits, will reach 7,400,000 tons for the year ending Dec. 31, 1913.

Complete figures are not at hand, but it is estimated that at least 12,000 men worked an average of 210 days in and around the mines during the year. This in itself, is a good record, but the most gratifying part of it is that this success has been attained with a decrease in the number of lives lost.

Total Accidents Have Decreased

During the fiscal year ended June 30, 1912, thirty-seven fatal accidents occurred in and around the Kansas coal mines, whereas during the year ending June 30, 1913, twenty-eight men were killed at the same mines and in the year ending Dec. 31, 1913, there were but 27 fatalities.

When we consider the increase in the production of coal in connection with the decrease in the number of fatal accidents which have occurred, the contrast is just cause for elation and while it is conceded that accidents will continue to occur as long as coal is produced and the number will fluctuate from time to time, we are constrained to the belief that a strict observance of the mining laws by miner and operator alike, will have a great tendency to reduce mortality in our mines.

There is at present a strong disposition on the part of the operator and the miner in this field to observe and comply with the mining laws and with their coöperation and the efforts which are put forth by the Mine Inspection Department in regard to the enforcement of the mining laws of the state, it is hoped that the lives and health of the mine workers may in the future be properly safeguarded.

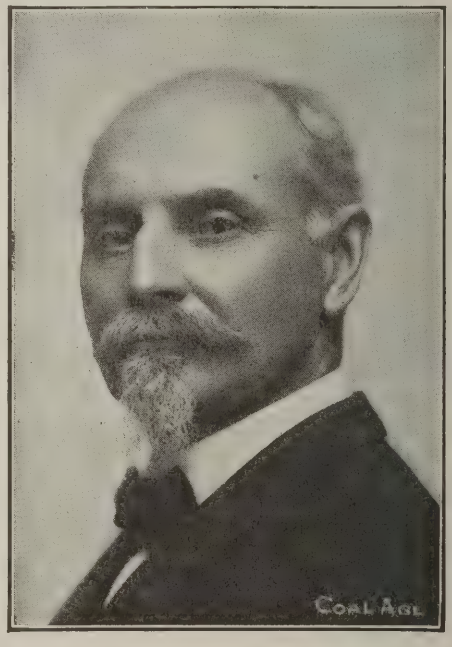
In many cases during the past year, it became necessary for the inspectors in the performance of their duties to resort to drastic measures in order to secure compliance with the mining laws. Several of the largest mines of the state were closed by the inspectors, principally on account of the poor condition of the ventilation found therein. Aside from this and a number of local strikes, work in the mines was not seriously affected during the entire year.

Recent Legislation

The last session of the Kansas legislature amended the Workmen's Compensation Law, which, while not perfect in all respects, is now one of the best measures of its kind in effect in the United States. The Bathhouse Law was also amended. The size of lockers, number of sprays, the kind and condition of the bathhouse to be maintained at all the mines within the state is now specified in the statutes.

A powder law was also passed by the same legislature and was agreed to by the miners and operators. By its provision the powder is delivered to the miner at his working switch in 25-lb. kegs. This latter provision doubles the size of the package and consequently increases the danger from explosives in the mines.

An appropriation of $3500 was made at the direction of Governor Hodges for the purpose of erecting a building at Pittsburg to house the Government Bureau of Mines' rescue car and for the purchasing of mine rescue apparatus.



Quite recently a number of steam shovels have entered the field and the stripping of coal by this method is progressing at a rapid rate. The production of Kansas fuel by this means will, therefore, during the next year, reach a large figure.

Kentucky

By C. J. Norwood*

SYNOPSIS—Kentucky has increased its production, due to the opening of new mines, but both cars and labor fail to square with the demand.

Incomplete returns for 11 months of the past year indicate that the output for the year will be about 18,500,000 tons, but the estimate must be accepted with due caution. The increased tonnage is chiefly due to new development. There were no strikes of moment, but the production has been adversely affected by the interruption of traffic resulting from the Ohio Valley floods, and occasional car shortages, especially in the eastern field. There has also been much complaint of labor shortage in that section.

C. J. Norwood, Kentucky

The coke output has increased but I would not hazard an estimate as to the amount produced. There has been a decreased number of fatalities and no explosions.

If the ventilation is defective in any portion of the mine or in the entire mine, the foreman should not hesitate to withdraw the men from the areas affected. It is only by such vigorous measures as this that serious mine disasters may be averted.

*Chief inspector of mines, Lexington, Ky.

Maryland

By William Walters*

SYNOPSIS—It is impossible to state at present the total production of Maryland for 1913, but it is believed that this will be somewhat below that for 1912, which was 4,085,817 tons. There were no serious labor troubles and only nine fatal accidents reported between May 1 and Dec. 23.

In reviewing the coal mining industry of Maryland for the year 1913, it will not be possible to give the exact figures at the present time as to production. The tonnage will be somewhat smaller for 1913 than that for 1912, which was 4,085,817 gross tons, showing a decrease of 80,919 tons from that of the year 1911. The decrease is due to the fact that there were several coal mines idle during the greater part of the year. Some of these mines are good producers and from the best information available at present all the larger coal operators report a decrease, except the Georges Creek Coal Co., Inc., which reports a large increase.

The number of employees in the mines of the state will not be materially changed from that of the year 1912, which was 5703. The average time worked in the mines of the state will be greater than in 1912, which was 245 days.

During the fiscal year beginning May 1, 1913, there have been nine fatal accidents reported up to Dec. 23. Five were caused by falls of rock and coal, and the other four by mine cars. The reports of nonfatal accidents have increased owing to the compensation now paid through the Miners' and Operators' Coöperative Relief fund to employees who lose time on account of injuries received while discharging their duties. Before this act, there was little or no occasion to report minor accidents.

During the year, there were four strikes throughout the state, affecting four different mines, but these were only local at each of the places, and were not general strikes affecting other mines at the same time. Two were to secure the semimonthly pay and only lasted a short time. The other two were on account of trouble at the weigh scales, and were brief as they were settled within a few days after they occurred, and with practically no financial loss to either the men or the companies.

The new child-labor law which went into effect last year is being enforced by the mining companies in the state. Children under 16 years of age who wish to be employed in or about the mines are required to obtain an employment certificate from their parents before they have permission to work.

Michigan

By Thomas Kanary†

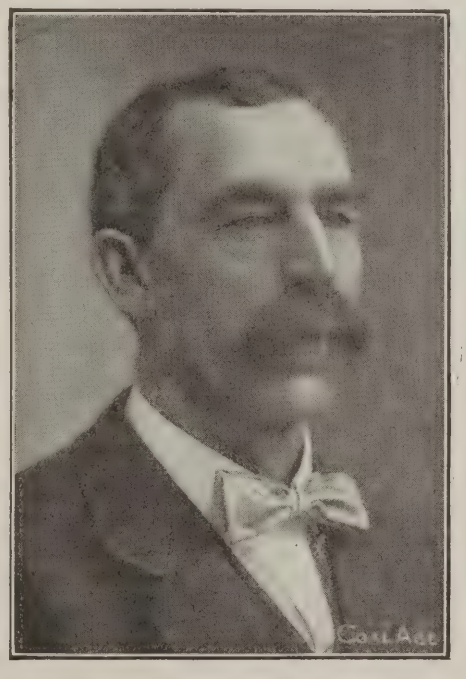
There are 22 mines in active operation in the state of Michigan, the majority of these being in Saginaw and Bay Counties. Two new mines were opened in the past year, one at Unionville, Tuscola County, by the Handy Bros. Mining Co., of Bay City, and one in Genesee County by the What Cheer Coal Mining Co., of the same town.

Seven mines were abandoned during the year, four in Saginaw, two in Bay and one in Shiawassee County. There were no strikes of importance. One suspension took place in September over a misinterpretation of the mining scale, but after a week's idleness work was resumed.

There were 169 accidents in and around the mines; two of which proved fatal and six were of serious nature, while 161 were not serious. As a rough estimate, I would figure that 900,000 tons of machine coal and 500,000 of pick coal were mined in 1913 in this state.

*State mine inspector, Midland, Md.
†State inspector of coal mines, St. Charles, Mich.

Missouri



By George Hill* and J. P. Hawkins†

The output of coal for 1913 will be about the same as for 1912, when it was 4,229,907 tons. The labor disputes in the coal fields were unimportant and few in number. The fatal accidents will be 50 per cent. less than last year.

Montana

By J. B. McDermott‡

The reported production of Montana for 1913 is larger than the output of last year, which year produced the largest tonnage on record in Montana. The larger mines were

J. B. McDermott, Montana

operated more steadily this year than last; there were few labor troubles or disputes and those which occurred were adjusted satisfactorily to both parties concerned with little loss of time.

Belt mine, which is the property of the Anaconda Copper Mining Co., was abandoned during this year. It has produced during the last 10 or 11 years some 2,000,000 tons of coal and employed from 200 to 600 persons. All the pumps, engines, rails and cars were pulled out. The

*Chief inspector of state of Missouri, Jefferson, Mo.
†Secretary, Bureau of Mines and Mine Inspection, state of Missouri, Jefferson, Mo.
‡Chief state coal mine inspector, Helena, Mont.

property will be leased for local supply and general commercial use.

New Developments

The Cottonwood Coal Co. is opening a mine in Fergus County near Windham at a place named Lehigh. The shaft, which is to have five compartments, has been in process of sinking since the middle of October. Two compartments of the shaft will accommodate two six-ton skips for hoisting coal; two others will be used for men and materials; and one compartment will be devoted to pipes, etc. The plant is to be modern in every particular, and it is expected to be as large, if not larger, than any other in Montana; James Pearson, manager of the Cottonwood Coal Co.'s properties at Stockett is giving personal attention to this Fergus County operation.

The Republic Coal Co., at Klein, is installing a battery of boilers in addition to those already in use. It is adding a dynamo and generator, electric pumps, and mining machines to its equipment. The shaft in Musselshell County formerly owned by Jacobs & McCleary, who did but little development work in connection with it, has been sold, if all accounts are true.

A rather peculiar condition obtains in our state. Last year 100,000 tons were shipped into Montana from North Wyoming; South Wyoming delivered 400,000 tons to us, and about 300,000 tons were shipped in from British possessions; yet, we are sending coal to Washington, Idaho and Oregon, and competing with these states and Canada in the markets.

Hydro-Electric Plants Compete with Coal

During the present year the Cottonwood Coal Co., at Stockett; the Nelson Coal Co. at Sandcoulee; the Lochray Coal Co. at Tracey; the Sand Coulee Coal Co. at Sandcoulee; James Brodie & Son at Belt; Calone & Johnson also at Belt connected with the hydro-electric line of the Montana Power Co. This power is used to run compressors, pumps, fans, drills, haulage motors, box-car loaders, shaker screens and pneumelectric undercutting mining machines. Not only the mines but the Butte, Anaconda & Pacific R.R., which hauls the ore from the mines in Butte to the smelters in Anaconda has discarded steam engines and runs all its trains, both in freight and passenger service by electric motors on power furnished by the Montana Power Co.

John D. Ryan at the head of "Amalgamated" properties says that the power company has already contracted with the Chicago, Milwaukee & St. Paul R.R. to furnish power for some four or five hundred miles of the line and yet less than a quarter of the possible water power in Montana has been utilized.

This hydro-electric development is a great competitor to the Montana coal mines, yet in face of its continued extension, we have a greater output this year than ever before and production will continue to grow greater in Montana for several years yet. The population in Montana is increasing rapidly; there are over 500,000 people in the state and branch lines are being added to many of the railroads. Our market will, therefore, continue to expand.

COMPARISON OF 1912 & 1913 MONTANA COAL MINES

	1913	1912
Mines reporting production to department	59	48
Machine runners employed	199	181
Loaders employed	506	563
Miners employed	1633	1538
Inside daymen employed	854	746
Outside daymen employed	576	570
Total number employed in and around mines in 1912	3768	3598
Production per man per day employed, tons	4.4	4.3
Total production	3,365,712	3,143,799
Value of output	$5,611,079.72	$5,600,097.00
Tons produced per life lost	224,381	314,380
Tons produced for each serious accident	46,732	66,890
Men employed per nonfatal accident	52.3	76
Men employed for each fatal accident	251	360
Death rate per 1000 employed	3.98	2.78
Serious accidents per 1000 employed	19.1	13.0
Kegs of powder used	80,550	72,740
Pounds of dynamite used	25,765	25,331
Tons of coal mined by machine	1,057,345	1,074,258
Tons shot off the solid and hand mined	2,308,368	2,069,540
Percentage of coal machine mined	31	34

North Dakota

By Jay W. Bliss*

SYNOPSIS—The mild weather of November and December caused a decrease in the production of lignite during the past year. Although 105 mines were in operation, but six fatal accidents have been recorded. The briquetting process, which is now being tried for the first time, is considered the most important event in the lignite industry.

The production of lignite in North Dakota for the year just closed was about 495,000 short tons as against 528,603 for the year 1912. The unusually mild weather which prevailed throughout the state in November and December is responsible for this decrease in tonnage, 30 per cent. of the total output being mined under normal conditions during these two months. It is estimated that not to exceed 20 per cent. of the total output for 1913 has been mined in the last two months of the year.

There have been in operation during the past year 105 coal mines, including a number of strip pits and small underground workings, employing on the average about 950 men during the winter and 350 during the summer. But six fatal accidents have occurred during the year. A number of small new mines were opened up during the fall of 1913, but the demand for coal has been so moderate they have not done a satisfactory business. The state

STATISTICS OF COAL MINING IN MONTANA IN 1913 BY COUNTIES

† Includes coal shot off the solid.

*State engineer, Bismarck, North Dakota.

as been free from any labor disturbances that could in ny way affect the production.

Much valuable research work has been done at the experiment station maintained by the state under the direction of E. J. Babcock, dean of the State School of Mines. process for briquetting has been worked out that is very romising, and the experiments with lignite as a producer f gas for power, heat and light, have been most satisfactory. It is to be regretted that a recent fire has temporarily crippled the work of the station.

A briquetting plant has recently been completed at Minot, and at this writing, operations have just begun. The success of this plant, which is the first of its kind in North Dakota, will mean much to the lignite industry.

JAY W. BLISS, NORTH DAKOTA

As soon as it is actually demonstrated on a commercial scale that lignite briquettes can be made and disposed of at a profit, abundant capital is ready to be invested in the undertaking. This will result in a development of the lignite mining business that will make it one of the big industries of the state. And North Dakota, having the largest estimated tonnage of workable coal of any state in the Union but one, cannot help but become a heavy coal producer.

The beginning of the briquetting process is considered as being the most important feature in connection with the lignite industry for the year 1913.

Ohio

SYNOPSIS—An increase of 9 per cent. marked the progress of the coal industry in Ohio during 1913. This resulted from the greater steadiness with which the mines in operation and the men engaged worked during that year as compared with former years. The Massillon district is the only section which did not produce as much coal as in 1912.

From all advance reports received from the several coal-mining districts in the state, the output of coal produced bids fair to exceed the output for any previous year. The tonnage for 1913 is estimated to have reached 37,500,000 tons, or an increase of about three million over the tonnage reported for the year 1912, when the output amounted to 34,444,291 tons, which at that time was the largest tonnage recorded; in 12 years the tonnage has almost doubled itself.

According to a summary of mineral production compiled by Edw. W. Parker, of the U. S. Geological Survey, for the year 1912 the value of the mineral resources of Ohio was $111,229,656, an increase of about $14,000,000 over 1911. Of the mineral products of Ohio, coal and clay are rivals for first place in value of production; the production of coal in 1912 amounted to 34,528,727 short tons, valued at $37,083,363, and the value of the clay products was $34,811,508.

Persons Employed

There will probably be very little change in the number of persons engaged in the production of coal during the year 1913. There was a shortage of labor in Jefferson County during the month of November, but this was of short duration as the weather moderated, and there was somewhat of a cessation of the unusually strong demand for coal at that time; this permitted the coal companies to handle with satisfaction the orders they had on hand, and there was, therefore, no coal shortage which, for the time being, seemed to be in store for the users of this kind of fuel.

The majority of large mines worked about full time, and the miners experienced a year of unusual prosperity, not only in time worked, but in wages accruing from the steady demand for the product of their labor.

Car Shortage

The usual draw-back of car supply manifested itself during the months of October and November, and bid fair to prove a severe handicap to the trade. This would undoubtedly have been the result but for the moderating weather which the month of December brought. This condition alleviated what might have been a severe shortage in fuel supply.

Review by Districts

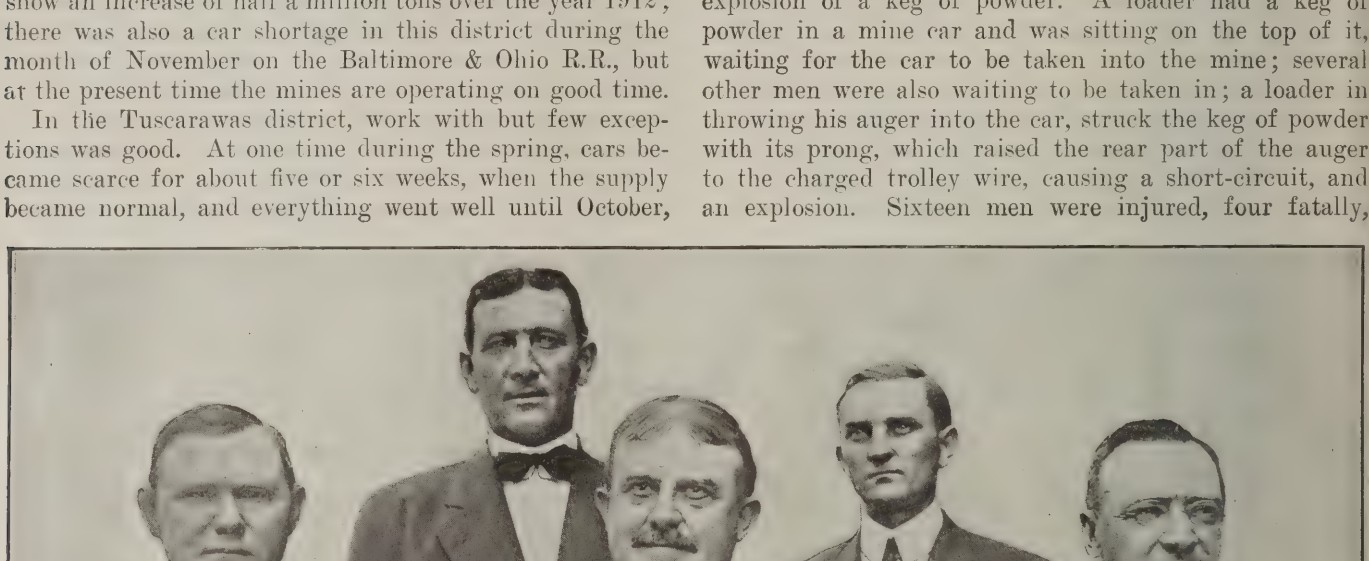
The Hocking district will show an increase in tonnage; the mines of this district worked steadily for the first nine months; about Oct. 1 a car shortage set in, and since that time they have worked about half time up until about Dec. 6, when conditions changed and work was again steady.

The eastern Ohio district will show a large increase as the mines worked full time, and there were no cessations except for repairs and improvements such as the building of tipples, and the installation of larger ventilating equipments.

In Jackson County the tonnage will compare favorably with that of 1912; the supply of cars was better than in former years: the Detroit, Toledo & Ironton Ry., which formerly had its drawbacks, gave better service this year.

Lawrence County will show a large increase in output over the years 1911 and 1912; at that time the large producing mines were on a strike; this was settled in November, 1912, and since that time they worked fairly well; it is estimated that the tonnage of 1912, which was 88,000 tons, will probably be increased to over 200,000 tons. The coal in this county is practically all run-of-mine.

The Massillon district, according to advance reports,



will not come up to the year 1912; there was a car shortage in this district also for more than two months, and the mines as a rule worked about two-thirds time.

The Crooksville district is reported as showing an increase, and the mines worked more steadily than in any other year, but a shortage of cars developed in September, and the mines for two months worked about half time.

The Cambridge district, taking as the standard one of the largest coal-producing companies, will show increases, notwithstanding the severe handicap of the floods, high waters, etc.; it is estimated that this company alone will show an increase of half a million tons over the year 1912; there was also a car shortage in this district during the month of November on the Baltimore & Ohio R.R., but at the present time the mines are operating on good time.

In the Tuscarawas district, work with but few exceptions was good. At one time during the spring, cars became scarce for about five or six weeks, when the supply became normal, and everything went well until October, when a shortage again manifested itself, noticeably on the Baltimore & Ohio. The Pennsylvania gave much better car service, but the mines located on this road only worked four days a week for several weeks. However, it is estimated that the tonnage of this district will show an increase of from 10 to 12 per cent. over the previous year.

The tonnage of Muskingum County is estimated to be about the same as for the year 1912; the car service, with but few exceptions, was good; the flood was a severe handicap to the mines of this county, and caused them to be idle for a long period of time; however, the mines that were not so affected, operated on better time than the previous year.

THE OHIO MINING COMMISSION APPOINTED TO DEVISE AN EQUITABLE PLAN FOR WEIGHING COAL

On the front row, beginning on the left: State Mine Inspector J. C. Davis, Judge Crow and Prof. M. B. Hammond. In the rear: J. M. Roan, an operator, and Morris Albaugh, a miner.

ACCIDENTS

The year 1913 will record a larger number of accidents than any year since the creation of the mining department. While it is true that there will undoubtedly be a much larger increase in tonnage, the accidents have increased out of all proportion to what they should.

An explosion occurred in the Imperial No. 3 mine, operated by the Imperial Mining Co., Noble County, Ohio, on the evening of May 17, 1913, between the hours of six and seven, at which time 27 men were in the mine. Work was being rushed for the completion of a new motor road, and according to testimony given at the coroner's inquest, no inspection had been made of the working places by the fireboss, and a workman is supposed to have entered one of the rooms, igniting a body of gas. The repair work had cut off the ventilation and permitted the gas to accumulate. Fourteen miners were killed.

Another accident of unusual cause occurred at the Jefferson mine No. 3, Piney Fork, Jefferson County, Ohio, on the morning of June 16, which resulted later in the death of four persons who were burned severely, by the explosion of a keg of powder. A loader had a keg of powder in a mine car and was sitting on the top of it, waiting for the car to be taken into the mine; several other men were also waiting to be taken in; a loader in throwing his auger into the car, struck the keg of powder with its prong, which raised the rear part of the auger to the charged trolley wire, causing a short-circuit, and an explosion. Sixteen men were injured, four fatally, their deaths occurring within two weeks after the accident.

The fatal accidents up to Dec. 23 number 163, and by the close of the year they will probably total 170. This would represent an increase of 25 per cent. over the number of fatalities reported during 1912, when 136 occurred. Of this number over 90 will be due to falls of roof and coal; 10 to shocks from electricity; 28 were due to mine cars, an increase of 116 per cent.; six were due to explosions of powder; 15 to explosions of gas; five to mining machines and motors, and seven to miscellaneous causes; at the present writing, falls of roof and coal will show a decrease in number as compared with the year 1912.

MINE FIRES

Mine fires occurred at two of the large producing mines of the state during the year, but with good management and careful judgment, no serious effects were caused by either, except the loss of the operation of both of them, as the fires necessitated the complete sealing of the mines. The first fire occurred at the New Pittsburgh No. 7 mine, and was supposed to have originated from a short-circuit on the trolley line, caused by a fall of roof. Arrangements were made immediately after locating the fire to seal the

mine, which was effectively completed in about four days time. The fire originated on Mar. 30, and on June 7 arrangements were completed for reopening the sealed portion of the fire territory; while no fire was discovered, an excessive heat was found in the fire zone, and it was decided to reseal that section of the mine. On Nov. 29, another inspection was made of this territory, and the fire found to have been entirely extinguished and permission was given to the management to clean up this portion of the mine and operate it with open lights.

The second mine fire occurred on Nov. 1 at mine 301, operated by the Sunday Creek Co., of Columbus, and located in Perry County, Ohio. This fire was located about 1000 ft. from the main opening, and it was considered useless to try to extinguish it, and work was begun at once to seal it and allow it to smother out. While the work of sealing the mine was in progress, several explosions took place, and the work was considered too dangerous and hazardous to continue. Orders were then given to commence to seal the mine from the outside, as it was connected with mine 302 operated by the same company, and was threatening to endanger that property also; this work was temporarily done on the night of Nov. 9, and the permanent stoppings were completed on the inside on Nov. 12.

Mine-Rescue Car

The general assembly of the year 1913, provided funds for the purpose of purchasing and equipping a mine-rescue car for emergency use in case of mine explosions, fires originating in mines, or for any emergency that might arise and the car will probably be ready for use in the early part of 1914.

Legislation

Several new laws were enacted by the same legislature affecting the mining industry of the state, and several amendments to old laws were also passed at that time, the most important of which were one relating to the right of action in case of death in a mine; another to the use of calcium carbide in the mines and a third relative to the approaching of abandoned workings. Another most important act of this legislature was the enactment of a statute creating the industrial commission of Ohio, superseding the state liability board of awards, abolishing the department of commissioner of labor, statistics, chief inspector of mines, chief inspector of work shops and factories, chief examiner of steam engineers, board of boiler rules, and the state board of arbitration, merging certain powers and duties of said departments to said industrial commission of Ohio, and granting said commission certain other powers, and repealing a number of sections formerly in force. This commission took charge of these several departments on Sept. 1, organized the work and will from now on administer and superintend the work formerly done by these different state departments.

Joint Resolution H. B. No. 38

Perhaps no question brought to the attention of the legislature in a number of years so vitally interested the persons connected with the mining industry of the state as Senate Bill No. 23, which related to the method of weighing coal at the mines throughout the state; the agitation both pro and con became so animated, that it resulted in the passage of a joint resolution providing for the appointment of a commission to investigate an equitable method of weighing coal at the mines, and their report to be filed with the governor by Dec. 1. The commission was appointed and on Dec. 17 filed with the governor an exhaustive report covering its investigations of coal mining in this and other states, and recommending that miners be paid on the run-of-mine basis.

This commission also recommended legislation for the purpose of conserving our coal resources; for the appointment of safety mine foremen; for the regulation of solid shooting; to provide for emergency supplies, and to regulate the weighing of coal at the mine. This report, and the other legislation aforementioned, will be placed in the hands of the general assembly by Governor Cox, at a special session to be called in the early part of the month of January. New wage scales are to be made in April, so it would be difficult at this time to give with any degree of accuracy just what the state of the coal trade will be for the year 1914.

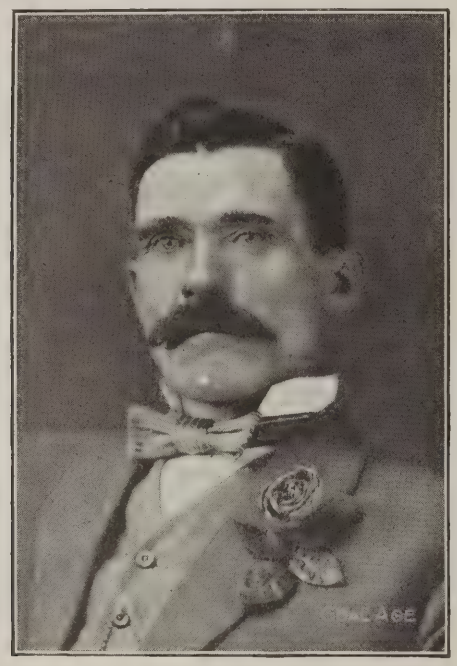
Oklahoma

By Edward Boyle*

SYNOPSIS—The closing months of 1913 showed a satisfactory increase over the production of the preceding year. Not only has the total output been increased, but the percentage of pea and slack has been reduced, securing a correspondingly greater amount of the larger sizes.

As the year of 1913 drew to a close the production of the mines became more gratifying, as it appeared to show a substantial increase over previous years. The output was, however, somewhat curtailed by three large producers, located in Haskell County, being idle almost the entire year. These were placed in the hands of receivers in 1912 and declared to be an unprofitable mining venture under the present scale of prices for dead work. Aside from this shutdown a few of the older mines in the McAlester field suffered a loss in production on account of a squeeze which threw them idle so far as coal production was concerned for several months. The total production for the year will reach approximately 4,000,000 tons against 3,600,000 for the year 1912 or a gain of 400,000 tons. The counties producing most of this coal are Cole, Pittsburg, Latimer, LeFlore, Haskell, Okmulgee, Tulsa and Craig. The present indications are that Pittsburg will lead in production, as in the previous year. Okmulgee County, which is known as the Henryetta field, will no doubt take second place in point of production. Okmulgee will, however, lead the state in machine-mined coal. Owing to the measures here being practically level or with but a slight pitch, machine mining is a practicable and successful method of operation in this field.

What is known as the McAlester field, or Pittsburg County, is just the reverse, having a pitch running from 25 to 45 deg., which makes machine mining impracticable or almost impossible. This year, however, will show a marked decrease in pea and slack coal over previous ones with a corresponding increase in lump and nut coal. The miner is, therefore, taking more care and exercising more judgment in preparing his product for market.



*Chief mine inspector, McAlester, Okla.

The total production of the different grades of coal produced in the last fiscal year which ended June 30, 1913, was as follows:

Lump, 792,995 tons; nut, 194,178; pea and slack, 532,927; run-of-mine, 2,277,799; total, 3,797,899 tons.

The gain and loss of the different grades of coal mentioned above over the year ending June 30, 1912, is as follows: Lump gained, 83,460 tons; nut gained, 13,271; mine run gained, 795,110; total, 891,841; pea and slack loss, 32,927 tons.

Oklahoma is now profiting by the strike in Colorado, which has been in the past, one of Oklahoma's strong competitors. Oklahoma coal is of good grade, which averages about 60 per cent. in fixed carbon. Several veins make excellent coke, many ovens having been built in this field but for several years these have been idle. There is no present indication of resumption of the coke industry

Edward Boyle, Oklahoma

in this field. There has been practically no changes in operating companies in the past year and but few new developments. Almost all land in Oklahoma containing coal is segregated by the National Government and leased through the Secretary of the Interior and for several years the leasing of coal lands has been discontinued.

As this is a very dangerous field almost all mines generating large quantities of gas and the dust being of a highly explosive nature, the decrease in fatal accidents in the past year over previous periods is highly gratifying and indicates better management and regard for the mining laws. The calendar year shows the death list to be 23. These met their death from the following causes: Falling rock, 11; powder burns, 3; windy shot, 1; runaway trip, 1; killed by cars, 4; gas explosion, 1; caught by cave-in in air shaft, 1; electrocuted, 1. The total number of non-fatal accidents was approximately 94. The total number of men employed both under and above ground was 9000.

The present outlook is considered bright and extensive improvements are anticipated during the coming year.

Pennsylvania

By Frank Hall*

SYNOPSIS—The production of the anthracite region has increased 6½ per cent. and of the bituminous fields 4½ per cent. Business has been brisk most of the year.

The great coal-producing territory of Pennsylvania maintained its annual habit of breaking all previous records of production. A careful estimate shows that the output in the bituminous region will reach the vast proportions of 168,000,000 net tons, and in the anthracite region about 90,000,000 net tons, making a total of 258,000,000 net tons. This amount equals about one-half the entire production of the United States and one-fourth the tonnage of the world.

The production in the anthracite region for 1912 was 84,426,869 net tons, and in the bituminous region 160,830,492 net tons.

Production by Districts

The estimated production in the anthracite region for 1913 was as follows:

District.	Anthracite Gross Tons	District	Bituminous Net Tons
1	3,976,000	1	5,000,000
2	4,974,000	2	8,900,000
3	3,217,000	3	3,600,000
4	4,300,000	4	4,800,000
5	3,450,000	5	6,000,000
6	4,580,000	6	6,000,000
7	5,500,000	7	6,000,000
8	4,132,000	8	5,000,000
9	5,116,000	9	7,500,000
10	5,025,000	10	4,750,000
11	5,500,000	11	8,300,000
12	2,883,000	12	6,066,000
13	2,275,000	13	4,000,000
14	3,150,000	14	7,000,000
15	2,790,000	15	6,000,000
16	2,999,000	16	7,000,000
17	4,637,000	17	6,010,000
18	2,750,000	18	4,500,000
19	3,150,000	19	8,825,000
20	2,400,000	20	6,300,000
21	3,516,000	21	7,000,000
		22	5,000,000
		23	6,750,000
		24	6,070,000
		25	6,010,000
		26	5,944,400
		27	4,860,000
		28	5,700,146

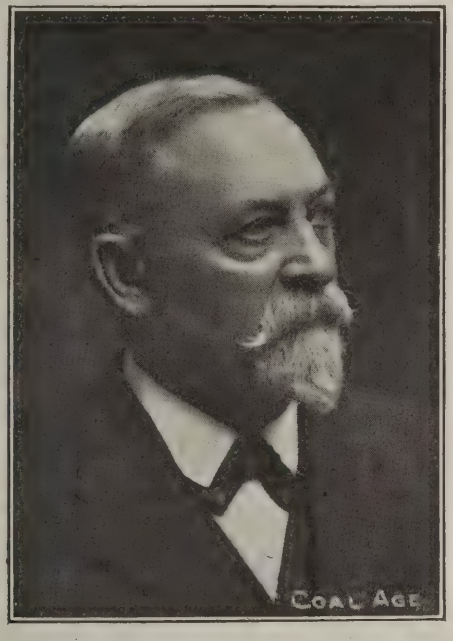
The coke tonnage is estimated at about 21,000,000 tons. The number of employees in the anthracite region for 1913 is estimated at 180,000, and in the bituminous region at 185,000.

Accidents

The number of fatal accidents in the anthracite region was 615, and of nonfatal accidents 1238. There were 526 fatal accidents in the bituminous region and 1164 nonfatal accidents. In both regions a regrettable increase in fatalities is recorded.

Two disasters of the year were of a serious character and resulted in the loss of many lives. On Aug. 2 an explosion occurred at the Brookside colliery of the Philadelphia & Reading Coal & Iron Co., in which 20 persons were killed. This explosion has never been satisfactorily explained. Various theories have been advanced as to its cause, but it still remains a mystery. The tragic aspect of this disaster is accentuated by the fact that while only two men were killed by the original explosion, 18 others (including the superintendent, the foreman, nine rescuers and seven tunnelmen) were killed by a second explosion caused by the tunnelmen igniting the gas

*Deputy chief, Department of Mines, Harrisburg, Penn.



released by the fall of a stump pillar following the first slight explosion.

In the bituminous region a disaster of far greater magnitude occurred at the Cincinnati mine of the Monongahela River Consolidated Coal & Coke Co. on Apr. 23, in which 97 lives were lost. This was an explosion of gas that had accumulated from a clay vein and was ignited by the naked light of a miner.

Labor Troubles and Car Supply

In the anthracite region there were strikes of brief duration in 13 of the districts. Many of these were what is known as "button" strikes. A strike of this kind has for its whole cause the objection raised by some of the employees to the employment of a few men, who do not wear the button, which is worn by members of the United Mine Workers of America as a distinctive badge. In some cases, the failure of even one man to wear a button will precipitate a strike.

In the bituminous region there were slight labor troubles and disputes in 11 districts. In both regions

James E. Roderick, Pennsylvania

the labor troubles and the occasional shortage of car supply probably reduced the production by 500,000 tons.

Safety Conditions

There is a very evident and general desire on the part of the operators to look after the safety of their employees. One prominent phase of this work is the establishment of hundreds of first-aid squads and of many rescue corps, the members of which are selected men, carefully and thoroughly drilled and supplied with the latest and most complete outfits for the successful conduct of this important work.

Outlook for 1914

In making predictions as to the trade in 1914, the inspectors as a rule are optimistic and a majority of them look for an increased tonnage. It is a difficult matter, however, to forecast the future of the coal industry. Its prosperity is so closely connected with the prevailing industrial conditions that a depression in almost any line of commercial activity is likely to prove disastrous. Just what effect federal legislation will have on the great corporations of the country cannot be predicted with any degree of certainty, but undoubtedly there will be a more or less protracted continuance of the present unsettled conditions, and the coal production will naturally be curtailed thereby.

What results may follow from the direct mining legislation recently enacted in other states, is another problem that will confront the mining people in Pennsylvania. But notwithstanding the acknowledged uncertain elements that will be factors in the near future, there is a general feeling of hopefulness pervading the trade.

Pennsylvania, Anthracite

Special Correspondence

SYNOPSIS—It is estimated that the 1913 anthracite production will exceed that of 1912 by about five million tons. Many improvements have been introduced, including cutting machines, steel mine timber, concrete dwellings, etc., that will render the year memorable.

Notwithstanding the popular notion that the number 13 is a "hoodoo," the year 1913 just passed may be considered as one of the most successful in the history of the anthracite-coal industry. In spite of the unseasonable weather during the latter part of the year, which seriously affected the consumption, it is estimated that the production for the entire year owing to the heavy shipments of the early months will pass that of 1912, by at least 5,000,000 tons.

This year will be remembered not so much for its production record, however, as for the renewed endeavor to reduce mine accidents and fatalities. Mine disasters on a large scale have never been common in this region. The past year has been marked by a development of modern practice in mining and the coöperation of the coal companies in bringing to bear concerted action to promote the education, safety, efficiency and welfare of the miners.

The advancement in the science of mining has been marked by the adoption of concrete and other fireproof materials in the construction of breakers and buildings, and in the substitution of steel and concrete for wooden timber underground. For the first time in the history of the anthracite industry, undercutting machines have been put into operation by several companies, and the increased production has proven them to be successful. The installation of several large subterranean pumping plants to remove millions of gallons of water per day in order to reclaim coal that heretofore had been thought irredeemable is another step forward in the development of the industry.

The increased use of electricity in and about the mines is also quite noticeable. Several of the older operations have added generators to their power equipment and some of the new ones to be opened up next year have already been designed to use electricity exclusively.

There have been but few serious labor troubles affecting the production of coal in Pennsylvania during the past year. Numerous local difficulties known as button strikes have occurred, but for the most part these were of short duration. In fact, the number of these petty button strikes during 1913 has been greater than all the similar

cessations during the previous 8 or 10 years put together. The effect of these small strikes on the coal output was noticeable but counterbalanced to a great extent by the slackness in consumption and demand due to the mild winter.

Numerous labor-saving, time-saving and safety devices added during the past 12 months have not only increased economy in production and preparation, but have also materially reduced the number of accidents in and about the mines.

There were more institute meetings, mining congresses and safety conventions held in 1913 than in any other single year in the history of the coal-mining industry. This is strongly indicative of the coöperative spirit of the numerous coal companies to promote their mutual welfare. Though the results already attained by this "get-together" attitude has been gratifying, it is hoped that the progress of the ensuing year will be still greater, for it will not be hampered by the peculiar difficulties which have been recently overcome.

To increase the production of coal without a coincident increase in the number of accidents has been the aim of the extraordinary efforts put forth by the coal companies in promoting the efficiency, safety and welfare of their employees. Some companies have appointed "Safety Engineers" to work in conjunction with their operating staff. Some have established "Efficiency and Safety Committees" to assist their inspecting department; some have increased their supervising force by adding a large number of assistant foremen or sub-foremen whose duties consist of keeping a double lookout with a view to accident prevention.

One firm has taken steps to educate its employees by publishing at its own expense an excellent magazine on mining. Lantern slides and moving pictures have also begun to play a prominent part in the promotion of the "Safety First" or "Accident Prevention" movement that is now popular everywhere. First-aid and mine-rescue work has also made considerable progress, and it is gratifying to note from the many contests that the men engaged in this excellent work have become highly proficient. Outside hospitals have been erected at nearly all the collieries in the anthracite field, similar to those built under ground some years ago.

The bathhouses, messhouses and clubrooms erected at many collieries throughout the coal region have added considerably to the comfort of the mine workers. In one locality concrete dwellings have been built on the Edison plan and are rented to employees at an exceedingly low rate. All these improvements indicate that progress has been made in the right direction and that mining of coal has been made much safer than it has ever been heretofore.

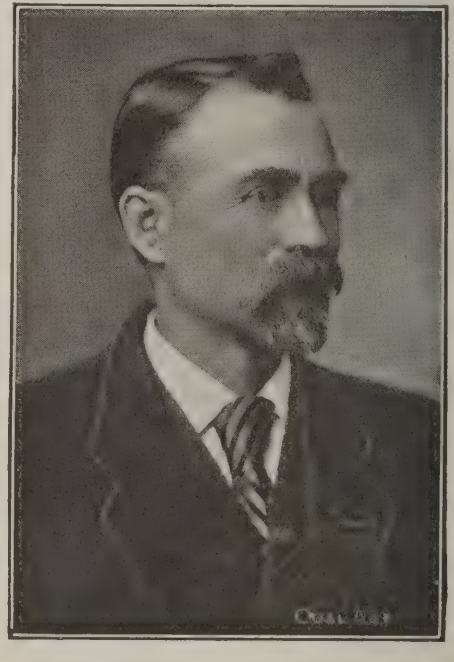
South Dakota

By Otto Ellerman*

SYNOPSIS—South Dakota coal mines are of such little importance that the inspector has no record of their output.

I have received frequent inquiries regarding the coal mines of this state and from what information I can gather, they are as yet few in number and small. Meade, Perkins and Harding counties seem to have small coal properties and these are worked during the winter months only, some employing as many as eight men. The coal is a very poor grade of lignite but it makes a satisfactory fuel for the homesteader and rancher. The price obtained is $4 per ton at the property and there is a ready market for the entire production. As yet I have been unable to gain satisfactory data as to the total output and the number of men employed by the industry.

*State inspector of mines.



Tennessee

By George E. Sylvester*

SYNOPSIS—Conditions in Tennessee have been about normal and the coal production may be roughly estimated as 6,600,000 tons. There have been no labor troubles, no serious disasters and only 33 fatal accidents during 1913.

As to the coal industry in Tennessee in 1913, it may be stated in a general way that normal conditions were maintained.

With the data at hand at present the output cannot be accurately stated; it probably did not vary materially

George E. Sylvester, Tennessee

from that of the year before, and might be roughly estimated at about 6,600,000 tons.

There appears to have been a slight falling off in the amount of coke produced, but as this tonnage is small, the total is quickly affected by a variation in the output of one or two of the principal operations.

There were no labor troubles reported during the year. Many of the mines, especially in the eastern district, report car shortage, and the time lost for this reason, especially in the busy season, was a serious handicap to a number of the mines.

The coal market in this state is largely local, and the mild weather of the fall and early winter kept the market from being as brisk as usual.

There were no serious mine disasters during the year. The number of fatal accidents which occurred was 33.

*Chief mine inspector, Nashville, Tenn.

The larger part of these were attributed, as usual, to falls of slate or coal. Many were classed as unavoidable, or due to the carelessness of the miner. The number while considerably larger than that of last year, which for some reason was abnormally low, does not vary greatly from that of the average of the state in the past.

There has been increased interest in first-aid work among the miners, more especially in the eastern coal field, and a highly successful first-aid contest was held at Knoxville in the fall. This was promoted largely by the miners themselves, through the Society of Tennessee Mine Foremen.

Legislation was enacted during the year requiring the keeping of first-aid supplies at mines, also in regard to the maintenance of mine-rescue corps. No change was made in the general mining law.

Texas

By Isidore J. Broman*

SYNOPSIS—The higher price of oil has made the coal business phenomenally good. The fatalities number about one per thousand men employed.

The year 1913 has been the most prosperous year in the history of coal mining in this state. The rise in the price of crude petroleum has practically eliminated competition from this source and the growing sentiment in favor of lignite as a cheap but valuable fuel has stimulated its production. In spite of the unsettled conditions on the border, which have caused a temporary decrease in the production at Eagle Pass and Laredo, the output for 1913, generally speaking, will be considerably in excess of that of last year, this increase being due to better market conditions and more uptodate methods of mining.

Bituminous Coal

I estimate the production of bituminous coal for this year to be about 1,300,000 tons, or about 150,000 tons greater than the production for 1912. The mine value of this output will approximate $3,000,000.

The bituminous mines are located in Eastland, Erath, Maverick, Palo Pinto, Webb, Wise and Young Counties, these mines employing about 4000 men. The largest mining company, the Texas & Pacific Coal Co., employs about 1500 miners with an average daily production of nearly 2600 tons. Union labor, exclusively, is employed in the bituminous field. There have been no labor troubles as all differences are settled by arbitration.

Lignite

The production of lignite may be estimated in round numbers at about 1,000,000 tons with a mine valuation somewhat over $1,800,000. About 1600 men are employed. The lignite mines of Texas are located in the counties of Bastrop, Hopkins, Houston, Lee, Leon, Medina, Milam, Rains, Robertson, Titus, Van Zandt and Wood. The largest mines are located in the county last mentioned.

The labor employed in the lignite mines is largely Mexican and negro. There has been a great scarcity of labor in the lignite field and production has suffered from this cause and from the unreliable class of labor employed. Much damage was done to the lignite mines and the railroads by the terrible floods which visited Texas during the fall.

Accidents

As regard the safety of mining the state of Texas can show a very good record. During the year 1912 the percentage of fatalities per 1000 men employed was 1.2. The percentage of fatalities for the present year will

I. J. Broman, Texas

probably not be in excess of one per thousand men employed.

During a heavy rain which caused the overflow of a creek and a cave-in, one mine in the Rockdale lignite field was partly flooded with water, imprisoning eight men. After heroic efforts seven miners were brought out alive after having been entombed six days. This is the only accident of the kind in the history of coal mining in Texas.

The average mine operator in this state is willing to do more than is legally necessary to make his mines safe and the enforcement of the law is accomplished with little difficulty.

Generally speaking, with improved mining methods, better market facilities and increased demand for Texas fuels by the industries of the state the outlook is good for a steady increase in the production of Texas coal.

*State mine inspector, Austin, Tex.

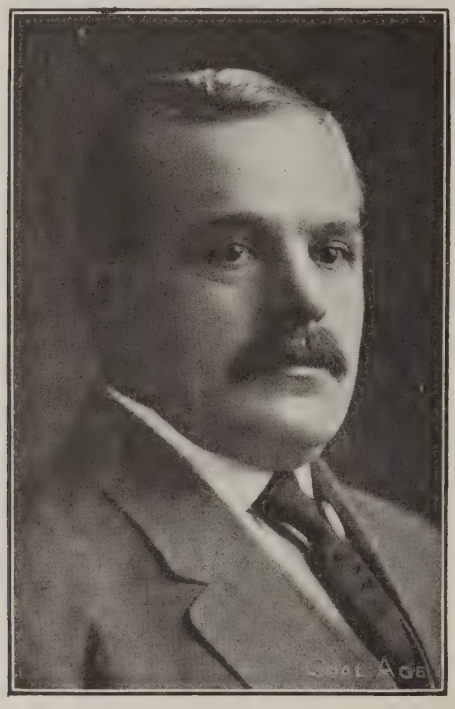
Utah

By J. E. Pettit*

SYNOPSIS—Output of coal increased 6.5 per cent., while coke production fell off 9.4 per cent. New mines made good showing. Sixty mining machines were installed. Outlook is for a banner year.

The coal output for the state of Utah for the year 1913, is 3,289,255 short tons, an increase of 200,899 tons, or 6.5 per cent. over last year. The production of coke is 314,694 tons, compared with 347,356 tons for 1912, or a decrease of 9.4 per cent.

*State mine inspector, Salt Lake City, Utah.



The main factor responsible for the decrease of the coke output was the disastrous fire, which occurred at Sunnyside, on May 26, when the No. 2 bridge and coal-crushing plant of the Utah Fuel Co. was burned. This accident caused a loss to the company of about $60,000, necessitating the working of the two mines, one by day and the other by night shift, and crushing the coal over an improvised bridge. The consequent unhandy manner of handling coal also cut down the output of the Sunnyside mines at least 100,000 tons.

A shortage of railroad cars in the fall also contributed to the small per cent. of increase of coal, but during the winter months no shortage of cars has so far been experienced.

Four thousand, six hundred fifty-nine men have been employed in and around our coal mines and coke plants during the year., showing an increase of six hundred seventy-one men.

New Operations Make Good Showing

While a good increase has been shown in the production of the old producing mines, some of the new operations

J. E. Pettit, Utah

have done well, notably the Storrs mine of the Spring Canyon Coal Co., with an output of 116,000 tons; the Willow Creek, or Castle Gate No. 2 mine, with an output of approximately 54,000 tons, and the American Fuel Co., with 50,160 tons.

Seventy-six new coke ovens have been built at Sunnyside during the past year and are now in operation, making a total of 726 beehive ovens now in operation. Seventeen fatal accidents occurred during the year, or 3.64 men per thousand. Twelve accidents occurred in the mines, and five on the surface at or near the mines. This is one less fatal accident than last year, when 16 men were killed in the mines and two on the surface. As a result of the fatalities this year, there are five widows and six fatherless children. There were also 39 serious and 60 minor accidents.

There were also 39 serious and 60 minor accidents.

The hydrocarbon output was 23,930 tons, a decrease of 9697 tons, or 2.8 per cent., due to the limited demand for this product in the Eastern market.

Coming Year to Show Large Increase in Output

The coming year is expected to show a larger increase than ever before in the production of coal. The Standard Coal Co., situated in Spring Cañon, expects to begin shipments of coal by Feb. 1, their tramroad, tipple, and railroad connections being practically completed. The Carbon mine of the Panther Canyon Coal Co., owned by the Sharp interests, has its tramroad, tipple and side tracks 90 per cent. completed, and will produce a thousand tons per day before the end of the year. The Cameron mine, one mile north of Castle Gate mines, will reach coal through a pair of slopes driven in rock 720ft., by Jan. 15, and will be a steady producer, with F. N. Cameron as owner and manager. The Ketchum Coal Co. will also commence operations during the coming year.

Some 60 mining machines of various standard types have been installed in the mines of the state during the year, and over one-third of the output has been undercut by electric and air machines. No labor troubles have occurred during 1913, and conditions as far as can be judged locally are favorable for a prosperous coal-mining year in 1914.

Washington

By James Bagley*

SYNOPSIS—The production of coal in Washington reached its maximum in 1910 since when it has slightly decreased. There have been but few changes in mine ownership and but 19 fatal accidents during the year.

In the year 1910 the coal production of Washington broke all previous records, reaching a total of 3,979,569 tons. Since that time there has been a slight decrease, owing to the substitution of oil for fuel on the railroads and many of the steamers running out of Puget Sound ports.

The reports received for the first 11 months of the year 1913 and a conservative estimate of the production for December added to this places the tonnage for the year at 3,677,946 tons, an increase over the previous year of 331,000 tons.

Coal is mined in six counties of the state, Kittitas County showing the largest production with King County a close second; Pierce, Thurston, Lewis and Whatcom Counties rank in the order named. Coke is manufactured in Pierce County only and will show an increase of about 25,000 tons over the preceding year, its production being approximately 49,000 tons in 1912.

There has been little change in the ownership of properties, the largest transaction being the purchase of the Summit mine located near Cle Elum in Kittitas County by the Roslyn Fuel Co. This is being reopened.

There have been no strikes of any importance during the year, the mines at Renton and Bayne still working on the open-shop plan. There has been no change in the wage-scale agreement, which runs for two years, and does not expire until Sept. 1, 1914.

*State mine inspector, Seattle, Wash.

There have been 19 fatal accidents for the first 11 months of the year, the largest percentage of these being from falls of rock and from mine cars. The most serious accident was an explosion of gas at the Divide mine in Lewis County on Nov. 6 in which three men met their death

The legislature of 1911 provided for the appointment of a commission to revise the laws regulating the operation of coal mines. This commission compiled a code, which was submitted to the 1913 legislature, which failed to include it among the laws passed. This is to be deplored, as both the miners and operators were represented on this commission, and it was supposed that they had compiled a code that satisfied both.

Most of the large companies are taking an interest in rescue and first-aid work, and most of them have rescue apparatus at their mines. The Bureau of Mines foreman for the Seattle station goes to the different mines to train men in this work and in this way it is believed better results are obtained than by waiting for the men to be sent to the station.

West Virginia

By Earl A. Henry*

SYNOPSIS—In 1913 the production in West Virginia probably increased 8½ per cent. despite the important labor troubles. The development in this state is so rapid that a record increase in output is expected this year.

From the records at hand in the Department of Mines of West Virginia, the total production of coal in 1913 in this state was approximately 71,700,000 tons. There were 3,000,000 tons of marketable coke produced. Thus in the year 1913, the coal production increased about 5,600,000 tons, and the output of coke, 2,000,000 tons. It will be seen from the above figures that the production in this state has materially increased, notwithstanding the general unrest of labor.

Effect of Strike on Tonnage

During a period practically embracing all the first nine months of the year, there was a strike in the Kanawha field in the mines along the Chesapeake & Ohio Ry. Moreover there was a large reduction in tonnage in the New River and Logan County fields because of the unsettled labor conditions arising out of the strike in the Kanawha field proper. Had it not been for this strike and labor troubles of like kind all along the lines of the Chesapeake & Ohio Ry., as well as in other sections of the state, the production of coal for the calendar year 1913 would have been nearly 70,000,000 tons. In other words, the labor troubles caused the production to be about 6,000,000 tons lower than it would otherwise have been.

This increased production of 1913 over that in 1912 resulted from several causes: Increased development of the coal territory, added improvements and an attempt to utilize every opportunity to produce a maximum tonnage in response to the sustained strength of the coal market. The market for West Virginia coal has increased in the last 18 months and the prices for all grades of coal have steadily and substantially increased.

It is somewhat generally believed by the operators that West Virginia coal will never be sold so cheaply in the future as in the past. It is thought that the producers of coal have begun to realize what it costs to produce a ton of their product and they are not disposed to sell it at a figure lower than it costs them.

Remarkable Development in State

The development of new mines in West Virginia in the past 12 months is remarkable. At the present time, in Logan County alone, there are about 25 new mines being opened in the Winifrede, Island Creek, and No. 2 Gas seams, and it is estimated that within the next seven or eight months practically every one of these 25 new mines will be shipping coal, thus adding most materially to the production of 1914.

In Raleigh County, there is also extensive development and the mines in that section, especially those on the Winding Gulf branch of the Virginian Ry. are rapidly increasing their output. The tonnage originating on the Virginian Ry. in West Virginia is now nearing the half million mark and with the new mines being opened the production should in 12 months be doubled. Extensive developments are also being made in the Pocahontas and Fairmont fields.

Earl A. Henry, West Virginia

As practically 90 per cent. of the coal produced in the state passes beyond its boundaries, the prosperity of the coal industry in the state depends entirely on adequacy of transportation facilities. The railroads, especially the Chesapeake & Ohio, have failed in some cases to keep pace with the mining development.

The Coal & Coke Ry., which passes for 200 miles through a rich country, has never equipped itself to handle the traffic which would naturally develop if facilities were assured. For this reason this road, which could have made its contiguous territory one of the most important coal fields of West Virginia, now passes over coal lands the greater part of which are undeveloped.

What West Virginia Might Do

There are working in and around the mines of West Virginia approximately 75,000 men, and there are about

*Chief of Department of Mines, Charleston, W. Va.

900 coal mines belonging to approximately 400 different companies. There is sufficient territory already developed in these 900 mines in which to place 30,000 more men, who could increase the output of coal at least 20,000,000 tons per year. Of course, there would have to be an improvement in the car supply. In my opinion, within the next 18 months or two years, when the mines now developed have been put into completed operation, West Virginia will have place, not only for the 30,000 men to which I have referred, but for 10,000 more. If this accretion of mining force and a like improvement of railroad facilities were secured, West Virginia could double its production in the next four years.

Judging from the figures already on hand, the West Virginia coal-mining death toll will be approximately 310 lives. A little over 200,000 tons has been mined per life lost. There have been no serious mine accidents. The majority of deaths and injuries have been caused by falls of roof. The next most important cause is electricity and the third cause in order of frequency is mine cars. The careless handling of these and the jumping from trips in motion cause many accidents.

Wyoming

By George Blacker*

SYNOPSIS—The production of Wyoming fell nearly 5 per cent. in 1913. The death rate dropped markedly. There were no labor troubles and no disasters.

Though only two less men were employed in 1913 than in 1912, the tonnage dropped from 5,500,253 to 5,229,817. It did not, however, fall below the output of 1911. The number of men killed fell from 35 to 21 and the number of injured from 120 to 65. Even the deaths from falls of roof and coal dropped 50 per cent.

TONNAGE AND MEN EMPLOYED—BY COUNTIES

County	Tonnage	Men employed
Uinta	42,243	101
Lincoln	1,849,113	1,839
Carbon	605,553	577
Sweetwater	2,732,908	3,153

SUMMARY OF COAL PRODUCTION

	1911	1912	1913
Total tons of coal produced	4,865,761	5,500,253	5,229,817
Employees in and about the mines	5,446	5,672	5,670
Fatal accidents	22	35	21
Non-fatal accidents	97	120	65
Coal mined for each life lost	221,170	157,150	249,038
Employees for each life lost	248	162	270
Killed per thousand employed	4.1	6.1	3.7

CAUSES OF DEATHS.

	1911	1912	1913
Gas explosion	1	0	0
Dust explosion	0	7	0
Falls of roof (coal or rock)	14	18	9
Falls of coal not in roof	0	6	2
Mine cars and haulage motors	3	3	7
Premature blasts	3	0	0
Powder burns	1	0	0
Falls of timber	0	1	0
Machines	0	0	1
Electrocutions	0	0	2

The year ending Sept. 30, 1913, was entirely free from labor troubles and disasters. Labor has been in constant and steady demand. The percentage of fatal accidents has decreased to a point lower than at any time during my official term as inspector of coal mines. I am receiving the active coöperation of the mine managements in all precautions I recommend them to take. Not only do they coöperate with me, but many of them go farther and take the initiative in devising means for reducing injuries and fatalities to a minimum. This is notably so with some of the larger companies, which are sparing no expense to bring about conditions of safety.

Concrete Stoppings

The life and well being of a coal mine, might be truly said to depend upon the character of its stoppings. If they are built improperly, if they are frail and leaky, then they cannot answer the purpose for which they were intended. The ventilation, and, therefore, the safety of the mine can only be maintained by building the stoppings in accordance with the best methods, and the material used in their construction should be such as will require no more attention during the life of the mine. Such stoppings can be constructed easily and cheaply, by pouring concrete into a form made of props and boards erected in the crosscut. These can be removed after the mixture has had time to set. These stoppings are being introduced into some of the mines and are proving to be entirely suitable. The Union Pacific Coal Co. has purchased a car, which is being equipped in the same manner as the rescue cars belonging to the government. Should an accident occur in any of the mines along the Union Pacific R.R. this car will at once be available, together with a splendid team of trained workers, under the direction of a capable man.

Explosives

Much experimenting has been done with permissible powders with varying results. When the coal is fragile or brittle, the force of the blast has the effect of shattering it into slack and thereby rendering it unfit for commercial purposes. On the other hand, a hard, tough coal is best mined with such high-powdered explosives, because more force is required.

Some companies are extremely lax in their manner of handling powder. I have seen many kegs of black powder and fully 20 sticks of giant powder together with a box of caps lying in a crosscut, unprotected. Such a practice is reprehensible.

*Inspector of coal mines, district No. 1, Wyoming, Cumberland, Wyo.

The Sydney Coal Fields; Cape Breton, Can.

In his report for "The Coal Resources of the World," D. B. Dowling states that: The Bridgeport mines have galleries on the Phalen seam extending over a mile from the shore of Indian bay, and mines at Table head have workings one and a quarter miles beneath the sea on the Hub seam. On this bed, at a distance of a mile from the shore, small rolls or undulations parallel to the coast were passed through. These are the only disturbances in the regularity of the measures and it therefore seems possible to extend the workings everywhere to the limits of haulage and ventilation. In the estimate of the amount of coal, the limit for probable reserves is fixed at 3 miles from shore and that for possible reserves at 5 miles."

The moisture runs from 2.4 to 5.4 per cent. in the mine and from 1.6 to 4 per cent. after air drying. The dry coal has from 34.7 to 37.3 per cent. of volatile matter and the fixed carbon varies from 53 to 59.5 per cent., while the ash is extremely variable, running from 4.8 to 12.3 per cent., the sulphur being included in the estimate. This sulphur runs between 1.8 and 6.4 per cent., but excluding the Gowrie seam, the average is slightly over 2.4 per cent.

Foreign Coal Production

British Columbia

By E. Jacobs*

SYNOPSIS—The labor trouble in Vancouver Island caused such a shortage of coal in western Canada that the tariff revision failed to deflect the market. The Puntledge River hydro-electric project is now supplying coal mines with power.

Labor troubles in the coal mines of Vancouver Island caused a decrease in their production in 1913 of nearly 40 per cent. as compared with 1912. The coal produced in Vancouver was 1,745,193 tons (1,558,208 long tons) in 1912 and 1,078,134 tons (962,620 long tons) in 1913.

In other producing districts in the province there was an increase in output which in part offset that decrease, so that the percentage of loss in production in the whole province, as compared with 1912, was a little less than 15 per cent., the total for the two years, respectively, having been 3,388,794 tons (3,025,709 long tons) for 1912 and 2,885,313 tons (2,576,172 long tons) for 1913. The quantity of coal made into coke was larger in 1913 than in 1912, 492,902 tons (440,091 long tons) as compared with 444,534 tons (396,905 long tons), which further reduced the net total of coal sold or otherwise disposed of as such. The net output of coal in 1913 was 2,392,411 tons (2,136,081 long tons), as compared with 2,944,260 tons (2,628,804 long tons) in 1912.

The districts in which coal was mined, and the proportions of production of the various mining companies, are shown in the following table:

PRODUCTION OF COAL IN 1913

	Long Tons	Short Tons
Vancouver Island:		
Canadian Collieries (Dunsmuir), Ltd.	562,705	630,230
Western Fuel Co.	218,691	244,934
Vancouver-Nanaimo Coal Mining Co.	100,449	112,503
Pacific Coast Coal Mines, Ltd.	80,775	90,468
Total	962,620	1,078,135
Nicola and Similkameen:		
Inland Coal & Coke Co.	116,000	129,920
Nicola Valley Coal & Coke Co.	110,000	123,200
Princeton Coal & Land Co.	28,780	32,234
Several smaller producers	7,988	8,946
Total	262,768	294,300
Southeast Kootenay:		
Crow's Nest Pass Coal Co.	1,040,374	1,165,219
Hosmer Mines, Ltd.	237,500	266,000
Corbin Coal & Coke	72,910	81,659
Total	1,350,784	1,512,878
Gross production	2,576,172	2,885,313
Made into coke	440,091	492,902
Total production, net	2,136,081	2,392,411

While the foregoing figures for 1913 are subject to revision, owing to the production for the month of December having to be estimated, it is unlikely there will be any considerable difference between the total of output of coal as shown above and that the revised figures will show later.

A Record Output of Coke

The quantity of coke made in 1913 is estimated at 19,323 tons (285,110 long tons), all at collieries in Southeast Kootenay—252,524 tons (225,468 long tons) at the ovens of the Crow's Nest Pass Coal Co. at Fernie and Michel, and 66,799 tons (59,642 long tons) at those of the Hosmer Mines, Ltd. The total quantity of coke made in 1912 was 296,053 tons (264,333 long tons), 245,228 tons (218,954 long tons) by the Crow's Nest Pass Coal Co. and 50,825 tons (45,379 long tons) by the Hosmer Mines, Ltd., so that both companies show an increase in 1913. It is noteworthy that the production of coke in 1913 was the largest yearly output on record in the province, the highest previous total having been that for 1905—of 304,399 tons (271,785 long tons). No information is yet available as to where all the coke made in 1913 was marketed, but it is known that both the Granby Consolidated Co. and the Consolidated Mining & Smelting Co. of Canada, the former having copper-smelting works at Grand Forks, Boundary district, and the latter a lead and copper smeltery at Trail, West Kootenay, both in British Columbia, obtain their coke supplies from Crow's Nest Pass collieries in the province, although the British Columbia Copper Co.'s smelting works at Greenwood are supplied from the International Coal and Coke Co.'s ovens, at the Alberta end of the pass.

Vancouver Island Collieries

The strike forced upon the coal miners of Vancouver Island at the beginning of May by the United Mine Workers of America has continued unbroken ever since and has necessarily interfered with the important mine development, equipment and construction work previously undertaken by three of the Island coal-mining companies. However, much progress was made by the Canadian Collieries (Dunsmuir), Ltd., with its improvements at Comox colliery, and the Pacific Coast Coal Mines, Ltd., also advanced its development and construction work at its Morden colliery, though not to the extent it would have done under favorable labor conditions. The Western Fuel Co. was much hampered by the strike, so that little progress has been made since last April toward bringing into production its new mine situated some 4 miles from Nanaimo.

Canadian Collieries, Ltd.

The Canadian Collieries, Ltd., operates two collieries, Comox and Extension. The hydro-electric power station and plant at Puntledge River was completed and has since been in successful operation. General Electric Co. equipment has been installed; transmission lines have been constructed to several mines and to the company's shops, coal washery, shipping wharves, etc., at Union Bay, and substations have been erected, and connections made at various other places for lighting purposes. A length of new railway, which cuts off the heavy grade on the old tracks, has been constructed, thus admitting of hauling to Union Bay heavier train loads than was previously practicable.

At No. 4 mine, development work has been made with the object of increasing output of coal. A new Sirocco fan was put in and ventilation of the mine improved. The old haulage steam-operated machinery is being gradually replaced by electrical installations. Similarly at No. 5 mine, steam-driven machinery has had to give way to an electrically-operated plant. No. 6 mine is still being worked by steam plant, but at No. 7, compressor, hoist, haulage plant, fan, etc., are all electrically operated; more miners' houses and other buildings have been erected, new railway sidings constructed in the yard, and many other improvements made.

No. 8 is a new line situated 1½ miles east of No. 7 and 4½ miles from the town of Cumberland. Two shafts, the main shaft measuring 11x22 ft., and air shaft, 11x18 ft., have been sunk to a depth of about 1000 ft. and the mine is being opened rapidly, some coal now being produced. A steel tipple, equipped with Marcus screen, has been erected, and 75 miners' houses have been built. The company's sawmill was destroyed by fire, but this is to be replaced shortly.

*P. O. Box 645, Victoria, British Columbia.

At the company's Extension colliery the production of coal is now only about one-seventh that of Comox—300 tons a day as compared with about 2100 tons—but when the new electric locomotives are received, in place of those destroyed by the strikers when they set fire to the surface buildings, a much larger output will be secured.

WESTERN FUEL CO.

Before the strike 1300 to 1400 men were employed at the Western Fuel Co.'s No. 1 Shaft, Protection Island, and No. 4 Northfield mines, but at the close of the year only about one-fourth that number were at work.

At the company's Reserve mine the two shafts, each 10 ft. by 25 ft. 9 in. within timbers, reached the coal at a little more than 1000 ft. Hoisting engines were installed, made by Andrew Barclay & Sons, Kilmarnock, Scotland; the main engine is 30x60 in., with Corliss valves and has two 14-ft. drums, the other is 26x54 in., also with Corliss valves, the drums being 12 ft. in diameter. Both are equipped with special devices to prevent overwinding. Transportation is provided by a standard-gage railway to the company's shipping docks and loading bunkers near No. 1 shaft, Nanaimo.

PACIFIC COAST COAL MINES

Not much change was made at the Pacific Coast Coal Mines' South Wellington mine. A larger compressor was put in, and more houses for miners were built. The output of coal is being gradually increased and it is expected that it will shortly be as large as before the strike.

At Morden, two miles east of South Wellington, the company sunk two shafts, a main shaft 9x16 ft., and an air shaft 9x12 ft. in the clear, and reached the coal at about 600 ft. early in the year, but development of the mine was prevented by the strike of the men, and the shaft was flooded. The high-pressure side of a Canadian Ingersoll-Rand compressor has been put in, also high-pressure steam boilers, altogether 450 hp., and a pair of 24x48-in. high-duty winding engines. The construction of a reinforced steel tipple and coal-washing plant has been commenced, and the installation of a fan, two direct-connected electric units each 150 kw., and the necessary work about the yard are in hand. It is expected this equipment will be completed by Mar. 1. Present development of the Morden mine shows a seam of coal 8 ft. in thickness.

The standard-gage railway track from South Wellington to the shipping docks at Boat harbor, 7 miles, has been relaid with heavier steel.

At the company's Suquash mine, in the northern part of the Island, mine development, construction work, and equipment have been in progress while the miners have been on strike. A new shaft, 11x22 ft. in the clear is being sunk and a pair of slopes being driven to connect older workings with the new. The coal is regular, averaging about 6 ft. in thickness. There are two 150-hp. steam boilers and a pair of 24x48-in. winding engines. A number of new buildings have been erected.

The Vancouver-Nanaimo Coal Mining Co., having conceded the demands of the United Mine Workers of America, worked full-handed the greater part of the latter half of the year. Its production of coal was larger than in 1912, but there is little else of interest to note.

NICOLA AND SIMILKAMEEN

The Nicola Valley Coal & Coke Co. mined less coal in 1913 than in 1912—123,000 tons (110,000 long tons) as against nearly 160,000 tons (143,000 long tons). On the other hand, the Inland Coal & Coke Co.'s production figures are 130,000 tons (116,000 long tons) in 1912 as compared with 35,100 tons (31,300 long tons) in 1912. Diamond Vale Collieries continued of small importance as a producer. The Pacific Coast Colliery Co. is reported to have reached good coal.

In Similkameen district, the Princeton Coal & Land Co. made about the same tonnage as in 1912. The Columbia Coal & Coke Co. called a halt and sold its property, and the new owners are doing development work in another part of this field. The United Empire continued unimportant.

The only company from which information was received is the Nicola Valley Coal & Coke Co.; a summary follows:

Production for the year is estimated at 125,086 tons (111,684 long tons), this being a somewhat higher total than is used in the accompanying table, but allowance is made for a reduction in output in December. The decrease as compared with 1912 is accounted for by unfavorable mining conditions in the first half of the year. These have been overcome. Mines Nos. 7 and 8 were opened; in No. 7 the main slope is being pushed ahead, with working places being opened as progress is made. This is in a 16-ft. seam of excellent coal. No. 8 is promising, with 6 ft. 6 in. of coal, but development is yet too limited for any certainty. Present working conditions allow of an output from this colliery of 750 tons a day, with a gradually increasing capacity, but high railway freight rates so limit the market that output is kept down accordingly. The railway company itself, formerly a good customer, is now burning oil in many of its locomotives instead of coal.

The Inland Coal & Coke Co. has opened a new slope, No. 5, and is active both in developing its property and finding a market for its coal.

SOUTHEAST KOOTENAY COLLIERIES

Generally, the position at Crowsnest district mines shows improvement. Both the Crow's Nest Pass Coal Co. and the Hosmer Mines, Ltd., made a larger production in 1913 than in 1912. The Corbin Co. had to close its No. 1 mine, owing to a fire, from spontaneous combustion; as a consequence this mine was unproductive during the greater part of the year.

At Coal Creek colliery of the Crow's Nest Pass Coal Co., B seam, lying 320 ft. above No. 1 in the Coal Creek measures, was developed to a producing capacity of 500 tons a day. At Michel colliery, two new mines were developed on the north side of the valley, and a skip incline was put in to convey the coal from mines to tipple level. The skips or cages carry eight tons of coal down a grade commencing at 30 per cent. and being 60 per cent. at the lower end. The incline is 1280 ft. in length, and the skips easily controlled by rotary multiple brakes, travel that distance in 80 seconds. These new openings are expected to yield a profitable production throughout the ensuing year. Prospecting on the south side of the valley at Michel resulted in a new seam being found about 150 ft. above No. 3 seam; it shows a working section about 10 ft. thick and the coal is generally of good quality.

The output of coal from Coal Creek mines compares favorably with that of the last good year, while the quantity of coke made at the ovens at Fernie is estimated to exceed the previous highest record by nearly 10,900 tons or 9700 long tons.

There was no new development work undertaken at Hosmer colliery, of the Hosmer Mines, Ltd., during the year. The B incline was double-tracked and another drum added to the engine operating it. An 8-ft. diameter Sheldon Keith wheel fan was provided for ventilating No. 2 B south mine. A steam locomotive was obtained for the rock bank and for hauling boiler coal. The production showed a substantial increase 266,000 tons (237,500 long tons) in 1913 against 210,832 tons (188,243 long tons) in 1912. The coke output was 120,000 tons (107,143 long tons) as compared with 50,824 tons (45,379 long tons) in 1912.

No. 4 mine of the Corbin Coal & Coke Co., known as the "Big Showing," was provided with transportation facilities. This mine is situated nearly 1000 ft. above No. 1, the latter being near the valley level. In No. 1 mine the coal seam is nearly vertical and varies greatly in thickness. W. W. Leach, of the Geological Survey, described it as varying from a minimum thickness of 10 ft. to a maximum of nearly 250 ft. This great difference may be due to compressed monoclinal folding. At the upper mine the coal has been stripped near the top of the hill and it is shown in a synclinal basin about 370 ft. in width, the thickness of the coal near the center having been proved by drilling to be more than 100 ft. During the summer and autumn, coal in No. 3 mine was worked in opencuts by a steam shovel, and sent down the switchback standard-gage railway for shipment. The snowfall being heavy, opencut working is not practicable in winter, but about 150 tons of coal a day is being mined here underground.

No. 4 mine is a new opening made after a fire in No. 1 necessitated the closing of the latter. The seam in No. 4 is a branch off that in No. 1. Present production is at the rate of about 250 tons of coal a day. A Marcus screen has been purchased, but it will not be put in until next spring.

General Notes

Little progress was made toward the extensive development of the newer coal fields in the province, these being without railway transportation. Some development work was done, both in the Groundhog Basin in northern Skeena, and in other fields in the southern part of that district.

The removal of the tariff on coal entering the United States has not yet made much difference in the quantity exported from British Columbia. No doubt later it will favorably affect both the Crows Nest district and Vancouver Island mines, but this year the latter have not been able to supply the British Columbia market, the strike of miners having kept down production. In fact,

much coal has been imported from the state of Washington and elsewhere to supply demands from the coast cities of British Columbia.

Saskatchewan

By Frank B. Smith*

Coal has been mined in the province of Saskatchewan for the past quarter of a century but not till within the last decade has any large operating company entered the industry.

Up to the year 1905 all the published records of coal production in the province were included in the statistics of the public works of the Northwest Territories, which included the new provinces of Alberta and Saskatchewan.

In that year the territory was divided and the records of each province kept separately. The returns made to the government in 1905 showed only 60,000 tons mined, but there is no doubt but that more coal was produced. There were a number of small mines in outlying districts producing a few hundred tons each per year. These failed to send in returns. Since then, however, a better account

F. B. Smith, Saskatchewan, Canada

has been kept of all the mines in operation in the province, the records showing a marked increase of production. The estimated output of coal for the year 1913 will be approximately 350,000 tons.

Small Mines Close Down Owing to Inadequate Equipment

Since the beginning of the mining industry in the province there have been over 50 mines opened, the greater number of them being on such a small scale that as soon as the haulage became an important item, the mines were abandoned. At the present time there are 30 mines in operation, and, of the yearly output, four of these are producing 85 per cent. of the total.

These are: Western Dominion Collieries, Ltd., Taylorton; Manitoba and Saskatchewan Coal Co., Ltd., Bienfait; R. Hawkinson Coal Co., Bienfait; Maple Leaf Coal Mining Co., Shand. Within the past two years there has been much activity in the sale and transfer of coal lands especially to companies which are already manufacturing brick or intend to make it. The clay which overlies the coal is of the finest quality for the manufacture of common and pressed brick and it is shipped all over this province and into Manitoba and Alberta.

Labor Conditions

Accidents at the mines are infrequent, even although the men employed are not the best of miners, the majority being homesteaders who find in the mines employment for the winter months.

A few years ago there was an effort made to organize labor but the conditions not being at all favorable the idea was eventually abandoned. There are a few local disputes between the operating companies and their employees, but these are all amicably settled.

Coal Resources of Saskatchewan

In the "Coal Resources of the World," Saskatchewan is credited with having a coal area of 7500 square miles. The estimated quantity of coal in this area is given as 20,000,000,000 tons.

The coal is a lignite with a high percentage of moisture, which, owing to the variable temperature, is difficult to transport without a loss in weight and condition. The average analysis of this coal is: Moisture, 28.84; volatile combustible matter, 32.15; fixed carbon, 34.61; ash, 4.40; total, 100 per cent.

The lignite coal of the province of Saskatchewan is similar to and of the same geological age with the lignite coal of North Dakota. That state through the mining engineering department of its university has during the past few years been making extensive experiments relative to the use of lignite for the production of gas and briquettes and these investigations have been successful from a commercial standpoint.

With the same idea in view, Saskatchewan has lately established a carbonizing plant at Estevan from which good results may be heard in the early part of next year.

*Inspector of mines, Saskatchewan, Canada.

Nova Scotia

Special Correspondence

SYNOPSIS—Every condition being favorable, the production of Nova Scotia increased 6½ per cent. during 1913. The fatality rate was about 3.6 per 1000 men.

The production of coal in this province in the year 1913 was about 8,400,000 tons (7,500,000 long tons), the largest for any year in the history of our coal industry. This exceeds the previous year's output by half a million tons, and was produced from 39 mines, 27 of which are in Cape Breton Island.

The conditions at the mines were generally good. There were no strikes; the demand for coal was strong; the season was favorable for shipments, and barring a scarcity of labor for a short time during the summer, there were favorable conditions to warrant our largest year's production. The larger coal companies are arranging to secure more men for this year's operations.

There will be a larger tonnage dumped this winter, if

conditions are as favorable as they were last year, and with the continued strong demand for coal, 1914 promises to be another record breaker.

Old Mines Are Being Reopened

The physical condition of the collieries is good. Six mines have been reopened during the past season. The Cape Breton Coal, Iron & Ry. Co. has reopened the Broughton mine, and a small shipment has been made at Louisburg, over the Sydney & Louisburg Ry., the coal company not yet having a shipping wharf. There should be a considerable output from this mine this year.

The Dominion Coal Co. has reopened the old Victoria mine, in the Sydney coal field, which mine, up to 20 years ago, was a good producer. The Emery mine, of the Dominion Coal Co., at Glace Bay, has been placed again in the producing list. The Nova Scotia Steel & Coal Co. will have another mine in operation this year, which makes six for this enterprising corporation.

The Scott pit of the Intercolonial Coal Co., Pictou County, was reopened last year, and the Minudie Coal Co. has added another mine to its operations in Cumberland County.

There is much undeveloped coal land awaiting demand. The area under lease is about 1200 square miles.

There were employed last year, exclusive of railway, stevedore, and clerical staffs, 13,664 men. There were 147 accidents, 49 fatal and 98 nonfatal.

The coke production was 815,401 tons, or 738,037 long tons, exceeding the previous year's production by 139,255 tons, or 124,335 long tons. There were no transfers of important coal properties during the year.

Present Conditions in the Coal Fields of Mexico

Special Correspondence

SYNOPSIS—Practically all the coal plants owned by Mexican capitalists were destroyed. Properties of American and English investors were not molested. If peace should be restored, the plants still standing will not be able to supply the demand of the country.

The troubles in the Coahuila field of Mexico began early in the year 1913 with a strike of the trainmen on the National Lines, which tied up completely all operations through entire lack of train service, and lasted for 15 days. This was followed early in February by the revolution against the Huerta government by Governor Carranza of the State of Coahuila, who declined to honor the authority of Huerta as President after the death of Madero.

The Revolutionists were able to take control of the part of the National Lines running from Eagle Pass, Texas, south to Reata, Mexico, where it connected with the other branch of the National Lines running between Monterey and Laredo. There being no local market between Reata and the border and the Revolutionists not being able to operate this road in connection with the rest of the National Lines which were under the control of the Federal Government, all railroad communication ceased and the mines were not able to ship any coal.

Hoping that this condition would only be temporary and in order to keep their forces together they continued mining coal and making coke until they had stored all that they were able to handle around their mines and coke ovens. It became necessary to suspend operations in April and since that time there has been no coal mined or coke produced in the entire region.

American Mine Not Destroyed

No attempt was made by the Federal forces under President Huerta to recover this railroad until September when an army was sent north along the line of this road, defeating the Revolutionists at Monclova and again at Hermanas. The Revolutionists as they retreated north destroyed the railroad bridges and the coal mines owned and controlled by Mexican capitalists. None of the American or English owned mines in that field were molested.

The first mine property that the Revolutionists came to on their retreat north was that of the Lampacitos Coal Company owned by the same group of Mexican capitalists that controlled the Agujita Coal Company and the Rio Escondido Coal Company near the border. At Lampacitos there were three mines in operation with a battery of 50 Koppers retort coke ovens and washing plant, electric pumps, and several hundred miners' houses and other buildings, including the residence for the assistant manager. Everything was either burned or blown to pieces by dynamite. The electric pumps in the mines are all under water and the estimated loss to this property is over $500,000.

Going north from Lampacitos they reached the junction point of Barroteran where the line to Musquiz leaves the main line and passed by the American owned mines at Las Esperanzas and completely destroyed the mines at Menor, owned by the Northern Coal Company, a subsidiary of the Monterey Steel Company. Here the destruction was complete and there is nothing left of the tipple, machine shop, store and other buildings that were erected on the property, and the mines are filling up with water. As these workings were already quite extensive, it is a question whether they can ever be profitably reopened. This branch line of railroad was also completely destroyed although it is owned by the Mexican Coal and Coke Company, who originally built it and leased it to the National Lines of Mexico for a term of years.

Bridges Also Destroyed

Going north from Barroteran on the main line they destroyed the large steel bridge across the Sabinas River, not only blowing up the piers with dynamite but setting fire to a train of coal cars that were on the bridge, so that the heat from this fire has warped the steel girders and made this $500,000 bridge a complete loss.

Turning northwest from Sabinas on the Rosita Branch

of the National Lines they reached the Agujita plant, which had the largest output of coke in Mexico, and announced that they intended to totally destroy this plant. Arriving, however, late in the afternoon they burned before dark a coal washery, the tipple at the No. 1 mine, machine shop, and a 2000-ton coal storage bin, and set fire to 52 other buildings, including the general office, manager's residence, hospital and school building, and at dark left telling the superintendent they would return in the morning and complete their work, but during the night word reached them that the Federal soldiers were catching up and they went on north without coming back the next day. The result was that the company has all its miners houses, tipples at two of its mines, with 400 beehive ovens in good condition, and all that they will need to start operation will be a new washery and an office building. Estimated loss at this plant is about $200,000 on surface improvements and, of course, there will be a heavy loss underground from the mines not being kept open.

To show the distinction made by the Revolutionists between the Americans and Mexicans; the superintendent and master mechanic of the Agujita Coal Company were Americans and the houses in which they lived were surrounded by the houses that were set on fire; the officer in charge of the Revolutionists detailed a squad of his men to climb on the roof of the two Americans' houses with water and to see that these two houses were not burned by the fire set to the adjoining ones.

A Madero Plant Was Not Molested

At the same time this destruction was going on at Agujita another squad moved on up the Rosita Branch, passing by the English owned mines at Cloete to the mines of the Rosita Coal Company and set fire to two of the tipples there. While these tipples were burning one of the office employees convinced the officer in control that the owners of this property were in sympathy with the Revolutionists, as the property was owned by the Madero family and Ernesto Madero, an uncle of the former President, was the president of this company. The officer thereupon called off his men although the coal washery and storage bin had been saturated with oil ready to set on fire. The Rosita Coal Company, therefore, got off with a loss of a little less than $50,000. There is a very valuable plant here of retort coke ovens and a first-class washery capable of handling over 1000 tons a day that would have been a heavy loss if they had been destroyed.

In the northern field just across the river from Eagle Pass, the Rio Escondido and Phœnix Coal Companies, although both owned and controlled by Mexicans, were not in any way disturbed by the Revolutionists.

The total damage to the mine property throughout this coal field will run into several millions of dollars. The camps are practically deserted with the exception of a few officials and enough men to man the pumps and boilers. Some of the mines are, however, being allowed to fill up with water as it proved too expensive to maintain the pumping.

The coal mines in Coahuila produced during the year 1912 over a million metric tons of coal and 250,000 metric tons of coke. In 1913 only 5000 tons of coal was shipped and very few cars of coke were able to reach the consumers before the railroad fell into the hands of the Revolutionists. There are now stocked at the various mines about 100,000 tons of coal and 75,000 to 80,000 tons of coke, but nothing can be done toward moving this until the railroad situation is cleared up and peace once more comes to that country.

Miners Become Revolutionists

The whole transportation system of Mexico, upon which these coal mines depend, has been torn to pieces.

After Destroying All of the Mexican Coal Plants, the Rebels Dynamited Bridges and Set Coal Trains Afire. This Shows the Sabina River Bridge

All the bridges, track, locomotives and cars in the coal field have been destroyed during this revolution. Even with the restoration of peace and the rebuilding of railroads, it will be many years before the working forces can be brought back into the mining region to equip the mines to produce the tonnage that was formerly obtained from them. Large numbers of these miners have left the country to obtain work in the United States and a great many have been killed in the various battles between the Federal soldiers and the Revolutionists, and such a large number have become professional Revolutionists, an occupation which they find quite congenial and much easier work than digging coal, that it will be many years before the mines of Northern Mexico can produce the coal and coke which they were able to extract and market in that republic during the years preceding this revolution.

With the restoration of peace and the reopening of the smelters there will be a heavy demand for both coal and coke, which should render the operation of the mines that have not been destroyed extremely profitable, as the demand will exceed the supply and prices can be obtained that were not possible when all the mines were in full operation.

Coal Markets and Business Aspects of the Fuel Industry in 1913

By A. T. Shurick

SYNOPSIS—Although a period of continued uncertainties in business, the coal markets developed an unexpected buoyancy and producers controlled the situation most of the year. Substantial increase in production. New legislation affecting the coal industry. Labor supply generally inadequate, though plentiful at the close of the year. The ineffective efforts of Connellsville coke operators to obtain higher prices. Some new problems in the marketing of anthracite.

The national coal market in 1913 was characterized by the highest average price level in the history of the trade. The year will be recorded as one of satisfactory business and substantial profits; it has been a period of rejuvenation, rehabilitation, restored confidence and general optimism.

Even though the close of the year witnessed a discouraging recession in the coal markets, 1913 cannot be regarded other than satisfactory. It was a season of great momentum, replete with readjustments that give tangible evidence of substantial progress to come.

Particular significance attaches to these facts in view of the generally adverse condition prevailing in financial circles, and the restrictive, not to say radical, State and Federal legislation enacted during the year. The situation in the world's money markets has seldom been worse. Standard securities of the most reputable description depreciated to a point scarcely exceeded by the spectacular panic of 1907, while a number of powerful corporations were forced into receiverships, including representative coal operations of national prominence.

In legislative circles a determined renewal of the dissolution proceedings against the Reading Company, the unexpected announcement of the Pennsylvania State Tax on anthracite and the deliberations of the Ohio Legislature regarding the screening law have all been restraining influences adverse to a more general expansion. In national affairs the abrupt passage of the new tariff and the long threatened new currency bill, finally enacted at the close of the year, had a depressing effect on general industrial conditions that must inevitably have been reflected back to the coal industry.

In the face of these grave uncertainties in commercial circles, it is, therefore, particularly gratifying to record such a substantial improvement in the fuel industry. The question arises: How has this been brought about? The self-complacement sales organizations of the large corporations are prone to ascribe it to good salesmanship, a general determination to obtain higher prices throughout the trade and a tendency to curtail production when such figures are not prevailing. The heavy increase in the output for the year does not justify the belief that there has been any important restriction in operations, while the spectacular break in the pool of the Connellsville coke operators seems to prove the faliacy of any concerted action in holding for higher prices.

But whatever the cause, the beneficial effects must not be gauged by a standard of dollars and cents. Of far greater importance is the psychological effect upon the consumer who has been brought face to face with the fact that he must be prepared to meet a constantly increasing advance in the cost of fuel. Higher mining costs, as the depths become greater, the increasing cost of labor, a gradual depletion of our coal reserves, and the necessity for a greater expenditure in mining in order to obtain a higher percentage of recovery will inevitably bring about this condition.

The year was replete with inconsistencies and contradictions. Perhaps the most striking of these was the general softeness and uncertainties which marked both the opening and closing periods, mid-winter seasons which are commonly the most active. On the other hand, a relatively high price level was struck early in the spring and rigidly adhered to through the summer months when business is ordinarily at a low ebb. But while the year was one of unexcelled prosperity, it was none the less a period of great anxieties and uncertainties.

Production

The production in 1913 reached a total of about 562 million short tons, exceeding the previous high record of last year by more than 30 million tons; of this increase about four and half million is credited to anthracite. But while the general production of the country showed an almost normal increase, it is worthy of note that the output of hard coal has not advanced over the past three years. The tonnage in 1913 only just made up the deficiency of six million tons, caused by the strike in 1912, and failed to reach the record mark of nearly 70 million tons in 1911. The falling off was due to the abnormally mild weather prevailing over the closing months of the year, which are usually the most active of the season.

The shortage of miners in Pennsylvania tended to restrict the production of bituminous coal there, but the acute labor troubles in West Virginia materially broadened the market for the Pennsylvania product, and the output was heavy. Ohio produced 38 million tons, showing an increase of 10 per cent. Virginia, West Virginia and Maryland all made substantial increases in spite of the labor difficulties and unprecedented floods in the Ohio Valley which interfered with West Virginia shipments to the Lakes. Dumpings at the Hampton Roads piers exceeded a million tons several months during the year. The output in the Southern States was not, as a rule, so good, although Alabama scored an increase of a full million tons.

Illinois had a substantially larger production, but without any material improvement in the unsatisfactory market conditions there, while Indiana, although passing her 1912 production still failed to reach the record of 1910 when a long suspension occurred in neighboring states. The Southwestern States show a satisfactory increase with the exception of Missouri where a slight falling off is noted. The acute strike in the Colorado fields reduced

the output while all the other Rocky Mountain States either held their own or showed fair increases.

Transpotration Statistics

Thirteen Leading Coal Roads—A study of the statistics of the performance of the 13 leading bituminous coal roads presents some interesting comparisons. For the first 10 months of the year these lines (which handle about 35 per cent. of the country's production) reported a movement of 145 million tons as compared with 132 million for the same period last year. With the exception

COAL MOVEMENT

The following is a summary of the movement of coal and coke over 13 principal railroads during October and the first ten months of 1913 in comparison with 1912, in short tons:

	October		Ten Months	
Anthracite	1912	1913	1912	1913
Baltimore & Ohio[1]	184,252	166,214	1,267,222	1,226,938
Chesapeake & Ohio[1]	1,440	1,645	20,711	14,639
Erie[3]	761,360	794,528	6,202,725	7,283,826
Pennsylvania[1 3]	970,880	1,046,703	8,358,717	8,711,723
Virginia[2 1]	77	50	97	909
Total 5 roads	1,918,009	2,009,140	15,849,472	17,238,035

October			18,712,657	20,611,176
November			17,815,767	.....
December			17,929,632	.....
Total, 12 months			206,381,392	

[1] Includes coal from connecting lines.
[2] Includes company's coal.
[3] Does not include company's coal hauled free.
Note.—The Southern Railway hauled 351,220 short tons of coal during September, 1913, and 3,127,282 short tons during the nine months ending September 30, 1913.

of February and March the roads show a consistent increase in shipments for each month of the year as compared with 1912.

Anthracite Coal Roads—The shipments over the eight leading hard-coal roads for the year of 1913 totaled slightly over 69 million tons as compared with 63½ million in 1912. Because of the curtailment in mining in 1912, due to a suspension of six weeks pending the fixing of a new wage scale, production that year was six million tons behind 1911, so that the 1913 shipments do not show any substantial gain.

Pennsylvania Railroad—Total shipments of coke, anthracite and bituminous coal over this road for the first 11 months of 1913 amounted to nearly 70 million tons as compared with 63½ million for the same period in

PENNSYLVANIA RAILROAD

The following is a statement of shipments over the P. R.R. Co.'s lines east of Pittsburgh and Erie for November and first eleven months of 1912 and 1913 in short tons:

	November		Eleven Months	
	1913	1912	1913	1912
Anthracite	987,487	916,914	9,699,210	9,275,631
Bituminous	4,509,375	3,934,876	47,171,538	42,162,485
Coke	999,500	1,245,500	13,011,863	12,128,463
Total	6,496,362	6,097,290	69,882,611	63,566,579

1912. The movement shows a consistent increase throughout the year with the exception of February and March, during which time the tonnage fell off materially.

Baltimore & Ohio Railroad—For the first 11 months of 1913, the B. & O. handled [illegible] million tons of coal and coke as compared with 33½ million in 1912. A

BALTIMORE & OHIO

The following is a comparative statement of the coal and coke movement over this road for November and the first eleven months of 1912 and 1913:

	November		Eleven Months	
	1913	1912	1913	1912
Coal	2,939,975	2,864,734	32,091,742	29,140,169
Coke	343,387	435,001	4,350,800	4,318,122
Total	3,283,362	3,299,735	36,442,542	33,458,291

steady increase in the shipments is noted for each month with the exception of February and March, the increases being particularly noticeable during the mid-summer period.

Atlantic Coastwise Freights—Water rates on the Atlantic coast, Hampton Roads to Boston, were about 75c. per ton, or 5c. above the average for 1912. As high as 95c. to $1 was paid in January and February. The Reading rate, Philadelphia to Boston, was decreased 10c. per ton Mar. 15, but again restored Nov. 1. As a rule, tonnage was comparatively easy during much of the year. The most notable feature in coastwise shipping is the steadily increasing proportion of steam vessels going into this service each year.

Lake Shipping—The total receipts of bituminous coal at Milwaukee, Wis., amounted to a little over four million tons as compared with three and a half million in 1912. The combined bituminous and anthracite tonnage was four and a half million in 1912 as compared with over five million in 1913. Shipments of anthracite from Buffalo, which handles four-fifths of the Lake movement, amounted to over five million tons in 1913, as compared with less than four million in both 1912 and 1911.

Sault Canal Shipments

The movement through the Sault Canals for 1913 was as follows:

Month	U. S. Canal	Canadian	Total	Total 1912
Anthracite				
April	214,814	.....	214,814	.....
May	294,912	116,433	411,345	17,848
June	288,036	89,833	377,869	207,060
July	334,516	87,010	421,526	280,317
August	308,497	75,350	383,847	228,083
September	249,783	51,750	301,533	394,526
October	237,723	54,967	292,690	360,903
November	239,691	52,077	291,768	382,530
December	32,982	16,200	49,182	77,600
Bituminous				
April	378,490	135,894	514,384	46,779
May	1,878,482	497,921	2,376,403	1,606,243
June	2,043,001	558,301	2,601,302	2,062,375
July	1,971,380	523,410	2,494,790	2,265,837
August	2,044,782	521,538	2,566,320	2,081,865
September	1,463,861	593,495	2,057,356	1,392,911
October	1,309,245	388,576	1,697,821	1,392,914
November	1,007,432	338,021	1,345,473	1,466,563
December	174,560	49,955	224,515	385,506
Total	14,742,207	4,150,731	18,622,938	14,931,594

The movement through the Sault Canals in 1913 totaled 18½ million tons as compared with 15 million

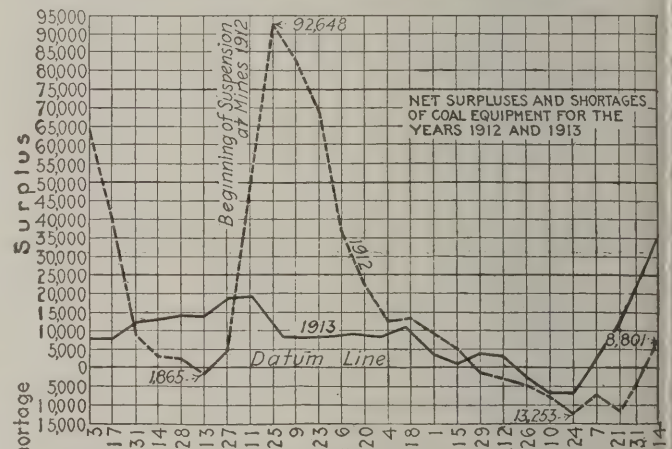
in 1912. Lake shipping was much restricted by the disastrous storm at the close of the season. Receipts at the Twin Points, at the head of the Lakes, were 11 million tons as compared with 8½ million in 1912. While arrivals have been heavy it is noted that the movement out was light and as a consequence there is a large supply on hand.

Holding the High-Price Level

As already noted, the salient feature of the 1913 coal market was the abnormally high average price level. The year opened relatively strong, but the market gradually declined through January, occasionally touching a point below the 1912 season's prices. Spot quotations were hammered severely by consumers, but in the face of these adverse conditions the trade showed a disposition to hold together on prices, and the market developed unexpected recuperative powers. Production was restricted through February and March, as reference to the railroad shipments will show, and as a result accumulations at the distributing centers were reduced and quotations held in an unprecedented manner.

When the contracting time arrived, Apr. 1, it was found that business was being closed at prices ranging from 10 to 25c. above last year's figures. While many of the large conservative buyers did not feel that conditions warranted such an abnormal advance, the possibility of serious labor troubles in West Virginia strengthened the position of the sellers, and the new prices were well maintained. The outlook was indeterminate for some time, but consumers were not disposed to take any changes and much business was closed, although usually with a guarantee protecting the purchaser against a serious decline. The buying interests gradually became the aggressor, and producers showed an inclination to be cautious about heavy commitments for the distant future.

The opening up of the Lake season, with indications of a heavy demand from the Northwest, had a further tightening effect upon the situation. The potential strength of the trade was conceded by all. In June, buyers, not yet covered, realized they had overstayed the market, and as a result there was a gradually increasing rush for coal which put the new prices on a firm basis with operators thoroughly in control. The further development of the labor difficulties in West Virginia tended to aggravate the situation, and many producers obtained prices that they had entertained little hope of ever receiving again.



It is interesting to review the conditions leading up to this abnormally high-price level. Large consumers have, in the past, had little difficulty in buying their entire requirements at almost any period of the year. As a result they have shown little inclination to bind themselves by contracts and even where such business has been done, the obligations were not usually regarded seriously.

During the winter of 1912 and 1913, however, an inflated condition developed and buyers in the spot market were forced to meet an excessively high-price level. The physiological effect of this experience was obvious, and when the contracting season arrived, there was a general rush to close. Those who failed to cover at this time found it difficult to do so later. Operators, on the other hand, were reluctant to sign contracts, anticipating another profitable season for spot coal. The Ohio Valley floods, involving a shortage of some ten million tons, and heavy requirements from the West, particularly in the Lake trade, also had some bearing on the situation.

New Channels of Trade

One of the most important changes in established channels of business was the large increase in the Pennsylvania grades in the New England market. The remarkable stability of these coals there occasioned great surprise in trade circles. This was due essentially to a broadening of the market for the Pocahontas, New River and Georges Creek fuels which are increasing rapidly in popularity, and are being more closely held for export and government use. There are numerous instances where the Pennsylvania varieties succeeded to the West Virginias, and they were even used, in some instances, in the export business.

With the possible exception of the extreme Northwest, it is not probable that the reduced tariff on coal will ef-

fect any important changes in the North American markets. The only foreign competition to be anticipated in the East is from Cape Breton coals in the coastwise trade. Since these are of rather inferior quality, as compared with the better grade domestic product, and as they also carry a high freight burden, it is improbable that they will be able to enter aggressively into the local situation.

The adverse conditions in the Middle Western markets were further complicated during the year. Many mines found themselves in financial difficulties while the big flood the early part of the period had a disastrous effect. The market for the Illinois product seems to be narrowing in all directions, due to competition with the non-union fields. There was also a gradual shrinkage in the tonnage of screenings over the close of the year as the effects of the water power developed by the new Keokuk dam became evident.

In general there has been a notably increased discrimination on the part of buyers during the year. Consumers have, in the past, been consistently governed by prices, but they are now awakening to a realization of the fact that a discrepancy of 5 or 10c. per ton in the mine price is scarcely perceptible in the cost at destination, whereas an important economy may often be effected.

Anthracite

The year opened with a shortage of some six million tons in the production of anthracite, due to the suspension in the early part of 1912. But the abnormally mild

emperatures, prevailing through the winter of 1912-1913 nabled the operators to pull through the season without ny difficulty.

The most notable feature in the hard-coal market dur- ng the year was the acute shortage of stove coal. So evere did this become that many of the operating com- anies put their egg coal back through the breaker in rder to make more stove. Egg coal proved the heaviest n the domestic sizes and the problem of moving this rade has developed into quite a serious one. Under xceptional pressure, as noted, this grade has even been ut back through the breaker, but, owing to the large pro- ortion of steam size resulting, this cannot be considered s practical.

Western shipments via the Great Lakes materially elped the situation and eliminated what would otherwise ave been heavy overshipping. Buffalo handles four- ifths of the anthracite movement by lakes to the North- vest. Shipments for last three years were: 1911, 3,917,- 29 tons; in 1912, 3,925,583 tons, and in 1913, over five nillion tons.

As had been anticipated, individual coal failed to fig- re prominently in the market. In spite of the fact that ubstantial concessions from the regular circular were reely offered in February and March, most consumers howed a consistent loyalty to the companies who had so dequately provided for their needs when a shortage eemed inevitable in 1912. Many instances of this kind ould be pointed out.

The unexpected passage of the Pennsylvania State law roviding for a tax on all the anthracite mined, proved disturbing element in the trade. Because of the un- ertainty as to the constitutionality of the procedure, ost of the companies refused at first to add this in- rease to the regular circular. As a result the customary hannels of business were disarranged, many consumers ithdrawing orders from companies charging the in- rease, and placing them with those that did not.

Since the matter could not be carried to the courts un- il the first collections were due, Jan. 1, 1914, it was im- ossible for many to determine just what stand to take in he matter. Where the tax was added the increase was itterly denounced by consumers on the ground that they ere being compelled to carry a portion of the Pennsyl- ania taxes. The close of the year found most companies aking the addition. The tax amounted to 2½ per cent. n the mine price of coal, which was figured at 10c. per n on the prepared sizes and 5c. on pea size. No addi- on was made to the steam grades.

In the Middle Western market hard coal has not been vorably received in recent years due to various causes. favorable business was anticipated this season until a rice war was precipitated in St. Louis which resulted in ch reduced prices that dealers were compelled to carry loss. One favorable result, however, was an increased opularity of the coal, due to the lower figures.

New rules and regulations regarding the movement at dewater and demurrage charges there were put in af- ct, some of which were severely condemned by the local ealers. The customary increase in both demand and rices occurred early in the fall, but the unseasonable eather experienced over the closing months caused a eavy slump and anthracite rounded out the year in poor rm, with collieries working under a heavily restricted roduction.

Connellsville Coke

The year in coke was marked by severe fluctuations and strenuous fights between buyers and sellers of the Connellsville product. The opening prices were high, but declined sharply in sympathy with pig iron. In July the market struck a $2.50 level, and held determinedly until October when it broke violently at first, gradually easing off to a $1.75 price. It developed later, however, that this quotation was mostly on off-qualities, and the close of the year found better prices prevailing generally.

While pig-iron production for the year showed some increase, the output of Connellsville coke did not share proportionately, due principally to the incursion of by-product coke into the Connellsville market. The future of this field will be determined principally by the rapidty with which the iron manufacturers adopt furnaces suitable for using byproduct coke. The trend is certainly in this direction, and many think the last of the Connellsville coal will be shipped to byproduct ovens.

Labor

Although the year was replete with labor troubles of all descriptions, it is gratifying to record a termination of the long drawn-out difficulty in West Virginia. On Apr. 25 the West Virginia miners voted to accept Governor Hatfield's proposition for a settlement, this having already been agreed to by the operators. A new precedent was also established in West Virginia, when President John P. White and 18 other officials of the United Mine Workers were indicted in the Federal Court on a charge of violating the Sherman anti-trust law by controlling prices. That President White and his lieutenants were scheduled for their full quota of trouble during the year was evident when a Federal Grand Jury in Colorado again indicted he and 24 others on a charge of maintaining a monopoly of labor by precipitating a strike there that continued over the close of the year.

The labor supply was an important factor in the market. Complaints were general in all the mining districts at the inadequate supply during the mid-summer period. Few companies had a full complement of men, while the uncertainties prevailing before the settlement of the West Virginia troubles did much to establish prices at the high level, already noted. As the market eased up toward the close of the year, and it became necessary to restrict production, a surplus supply developed and the year closed with more men than the operators could use.

In Legislative Circles

While no spectacularly radical legislation was enacted during the year, it was, nevertheless, a period of perincious activity among Government officials that was most disconcerting to the operators at times. That the tendency of both State and Federal legislatures is toward paternalism is no longer to be denied; while ultimate Government ownership in the coal industry is not even being considered in the present day, it is none the less apparent that the Government will no longer be denied the privilege of regulating and investigating commercial and industrial affairs that affect the prosperity of the country.

A notable development of the year was the enactment of a measure by the commonwealth of Pennsylvania providing for a state tax of 2½ per cent. of the market value, f.o.b. mines, of all the anthracite produced. The tax

proved a disturbing element in trade circles because of the lack of uniformity in collecting it, some companies refusing to add it to the circular until near the close of the year. It was asserted in some quarters that the tax would prove unconstitutional for the reason that it is not permissible for a local commonwealth to levy assessments on a commodity used in interstate commerce. Since the issue could not be tested until the first collections were due, Jan. 1, 1914, the measure is still in question. Pennsylvania also enacted a law requiring the anthracite companies to maintain hospitals, both above ground and in the mines.

The year in Ohio was marked by some anti-capitalistic legislation. In the early spring, a committee was appointed by the governor to investigate a measure presented by the miners of the state providing for a wage scale arranged on a mine-run, instead of a screen coal basis. Late in the fall the commission reported favorably on the measure with certain restrictions. A workmen's compensation law was also enacted. During the last month of the year, investigations were instituted with a view to effecting a reduction in freight rates from the Hocking district to the Lakes. The present tariff as compared with that from West Virginia is adverse to the local operators and the evident determination of the Ohio executive to protect local industries was received with much optimism.

Not the least important of the year's legislation was the passage of the Sundry Civil bill carrying a "rider" exempting labor from prosecution under the anti-trust laws. This measure was regarded as adverse to capitalistic interests and was returned to Congress for reconsideration by President Taft during his tenure in office. Organized labor has yet to prove that only the unionists shall have the privilege of working and certainly interference with the production of a commodity used in interstate commerce is clearly an infringement upon the basic intent of the Sherman act.

Conditions in General Business

While the coal markets were developing an accumulative strength with the approach of the fall buying season, the outlook in industrial circles became steadily more ominous. As early as May there were evidences of a congested condition in the world's investment market, and standard first-class securities could only be floated at a substantial sacrifice. The origin of the trouble was ascribed to the European war, following which came an abnormally large flotation of state, government, municipal, and corporation securities. Since it is mandatory on many of the foreign banks to subscribe for the issues of their respective governments, a heavy liquidation of American securities was precipitated.

The enactment of more or less radical legislation by the national government at about this time, still further aggravated the situation. Large business interests instituted retrenchment policies, manufacturing was curtailed and general industrial activities much restricted.

Thus in spite of a year of unprecedented prosperity, the unsatisfactory financial conditions prevailing resulted in some of the largest bituminous-coal corporations becoming insolvent. Following the announcement of financial difficulties involving the First-Second National Bank of Pittsburgh, controlled by the Kuhn interests, the United Coal Co. and several affiliated subsidiaries were placed in receivership in July. The O'Gara Coal Co. was the next to feel the pinch, a receivership being announced for this concern Sept. 15. Internal dissension among stockholders appears to have been the indirect cause of the difficulty, charges of mismanagement and misappropriation of funds being made. The early part of December brought the announcement of the insolvency of the powerful Pittsburgh-Buffalo Co. in Pittsburgh. The difficulty was due to strikes, floods and a shortage of liquid assets.

An important development of the year in business circles was the appearance of foreign capital in the local fields, particularly in West Virginia. As early as last January, D. A. Thomas, one of the leading figures in the British coal industry, and a specialist in export business, appeared in the United States with the avowed intention of investing. He made a rapid survey of the Eastern coal fields, and on a subsequent visit purchased a small West Virginia property, and further extended his inspection into British Columbia. There is no tangible assurance that he will become an active figure in the American coal industry as yet, but indications are highly favorable that such will be the case.

Toward the close of the year there were persistent rumors of a consolidation of the leading operators in the New River district, with a view effecting a sale to British investors. Reports indicate that the consolidation would be at a figure which would net present owners a handsome profit. A six-months' extension of the options was requested at the close of the year, indicating that difficulties were being encountered in the financeering.

The Fall Decline

It was inevitable that the combination of adverse conditions which developed in commercial circles must ultimately be reflected back to the coal industry. A feeling bordening on hysteria seemed to prevail among consumers during the closing months of the summer, with the result that they continued to drive operators for heavier shipments until, in September, surplus stocks began to accumulate.

The first definite break occurred in coke, when the pool of Connellsville operators, who had been holding firmly at the $2.50 level through July, August and September, lost control of the situation and the market fell off sharply. It was soon plain at this time that stocks were abnormal in all lines, and by the last of October the situation was definitely reversed; it was clear that there would be plenty of supplies for winter and the market became dull with spot prices only fairly well maintained though offering a stubborn resistance to any decline.

The closing down of navigation on the Lakes and the gradual awakening to the fact that the West had been overshipped, threw heavy surpluses on the Eastern trade, which could not be absorbed. The customary fall car shortage failed to develop, thus permitting a continuation of the heavy movement, while temperatures were abnormally mild during the closing months, and constructive element rapidly disintegrated. The demand fell off, premiums were quickly wiped out, and even cuts were made in the regular circular. The market slowed down steadily throughout the fall and the end of the year found practically no business being negotiated. This failure to round out the year in good form was the greatest disappointment of the season.

Review of the Export Coal Trade in 1913

By F. R. Wadleigh*

SYNOPSIS—More attention is being paid to the possibilities of foreign markets. American companies have had agents abroad surveying the ground. A number of fairly good contracts have been closed. American coal in South America.

The year 1913 saw the greatest awakening of the United States coal trade to the possibilities of the foreign markets that has yet developed; much systematic and continuous work was done to secure business in the Mediterranean and South American countries. While the actual shipments during the year did not show a great increase, it was not spasmodic and the efforts made will undoubtedly show gratifying results in 1914.

There has never been a better time to enter foreign markets. Freights are more nearly normal and enough local coals have been shipped and used to show that they can compete successfully with the better grade British fuels. The demand for coal in South America and abroad is steadily growing, prices are being maintained or raised, while the United States exporter is learning more about his competitors and the conditions under which he must compete, buying and selling methods, etc.

New River and Pocahontas have hitherto made up almost the entire volume of coal exports, but now gas and coking coals are also finding their way into the foreign markets. It has been found that there are large markets for these fuels, especially in Italy, and trials have proved that our product of this description is quite equal, if not superior to, the British and German coals that have hitherto had a monopoly of this trade.

There seems to be every prospect, then, that the steps taken in 1913 to increase our foreign trade, will lead to an increased tonnage and regular contracts. We now have a surplus of coal over home consumption and must find a market for it if prices are to be maintained and the business remain on its present profitable basis. But we are still facing the problem of variable ocean freight rates and supply of ship tonnages, as well as the return-cargo difficulty; until these obstacles are overcome, our efforts to secure an established coal trade abroad can never be entirely successful.

The visits to the West Virginia and Kentucky coalfields of D. A. Thomas, the most influential figure in the British export coal trade, president of the great Cambrian colliery group and director or chairman in some 21 mining, shipping and selling companies, gave rise to much speculation as to the possible effect of his visits on our exports of coal. It was thought that he had decided to make more or less large purchases or investments in coal lands on this side, with the South American trade in view especially and that his companies would handle United States coals abroad, just as the Westphalian Syndicate of Germany handles British coals. As yet neither coal-land owners or export agencies have been helped, whatever may be the ultimate outcome; the purchase, at a bargain price, of a small New River property, was the only actual investment made as far as is known though he is said to hold options on several large properties and has a permanent representative in this country.

*44 State St., Boston, Mass.

British Eyes on West Virginia Field

There is no doubt that some of the largest British coal interests, especially those interested in foreign bunker agencies, have given close attention to the West Virginia coal fields this year, probably on account of the near opening of the Panama Canal, which will undoubtedly open new markets to these coals. The British coal interests have probably not given more attention to the United States fields because their own business has been, and still continues, in such a prosperous condition, both as to prices and tonnages. The exports of British coals have been greater and the prices obtained higher in 1913 than in any previous year.

The Pocahontas Fuel Co., the largest shippers of Pocahontas coals and probably the largest exporters of coal in the country at present, have shipped during the year, about 250,000 tons of coal abroad; it is also stated by one of their officers that they have closed contracts for some 700,000 tons of export coal for shipment in 1914.

The Consolidation Coal Co. have their own offices in Genoa and have shipped a few cargoes to Italy during the year, mainly Georges Creek coal; this fuel has not, however, the heating value or low ash of the best Welsh or Monmouthshire coals. This company has shipped about 125,000 tons of screened Fairmont coal to the Egyptian State Rys. during the past 18 months, but does not seem to have secured any of this business for 1914, for reasons variously stated, but probably because it did not pay as well as the home markets.

It has been rumored that a large Pittsburgh coal company has secured important contracts for gas and steam coals abroad, some 5,000,000 tons being the total given; this amount is obviously incorrect; 500,000 is more likely the correct figure.

During the last two or three months much space has been given in the daily papers to the operations of a syndicate which had acquired options on most of the desirable New River coal lands and was said to have secured the necessary capital for purchase in England. Five million tons of this coal was to be shipped abroad and the United States export trade revolutionized. While there is no doubt that options had been secured on a large tract of New River land, although not nearly so much as was claimed, evidently the cash was not raised, as the return of their representative from England was followed by a request for six months' extension of the options and a further 90 days' grace.

American Coal Abroad

During the year several of the larger coal-selling agencies have had representatives abroad, with a view to future business, but it is not as yet evident what they accomplished as to future deliveries.

A small privately owned railroad in northern Italy has closed a contract for about 22,000 tons of United States coal, 1914 delivery, said to be Pocahontas coal, at a price of about $5.63 per gross ton, which, at prevailing ocean freights, will net the shipper about $2.72 f.o.b. Hampton Roads.

An opportunity was given one of the larger New River selling agencies last spring to supply a large tonnage, 240,000 tons, to one of the foreign state-owned railroads, but the deal fell through partly on account of the scarcity of suitable coal and partly because of price.

As yet the United States coals have made but little inroad into the foreign markets for manufacturing and railroad fuel, most of the coal shipped abroad having been for ships bunkers.

So far, the efforts of the United States shippers seem to have been largely centered upon Italy and with reason. While France imports more coal, a large part of such imports is made up of Northumberland and Durham coals, as well as Welsh, and the receiving ports, with two exceptions, are on the North French coast, where the United States coals cannot compete, owing to the short distance from the British shipping ports.

Exports to South America

The year's coal exports to South America have shown a healthy increase; it is in this direction that the greater possibilities lie for United States coals, as the consumption is already large and increasing every year with the development of the country, while the possibility of return cargoes is more likely. It is true that the British and Australian coals are holding their own in this direction, yet coals from this country have been tested with excellent results and some steady business been secured, especially in Brazil and the Argentine Republic.

Shipments from Hampton Roads to Para, Manaos and the Amazon have been kept up under existing contracts and the buyers have not only obtained good results from the use of the coals shipped, but have made money from their sales to users.

Although there have been rumors afloat during the year that United States exporters were to build colliers for the foreign trade, no steps have been taken, so far as is known, beyond the making of inquiries as to costs, etc.; the largest exporting company seems content to get into the foreign market and to await the return of lower ocean freights, with an increased supply of tonnage available, although the same firm is said to have lost an important trial order from the French Admiralty through inability to charter at the right time.

The building of new coal piers by the Norfolk & Western and Chesapeake & Ohio R.R., to be put in operation shortly (the Norfolk & Western pier in January and the Chesapeake & Ohio pier in March) will undoubtedly give an added impulse to the export trade, as these piers will ensure quicker despatch to ships and less breakage of coal in dumping.

An Awakened Interest in Export Business

The awakening of interest in the foreign trade during 1913 has been shown by the attention given the question by several of the coal-trade papers. But, with the exception of the Coal Age, none of these papers have paid much attention to the crux of the whole situation, namely, ocean transportation, nor have they discussed the proper methods of selling and handling our coals in foreign countries or the necessity of proper preparation to meet conditions. Yet these are the very rocks on which many of the efforts to enter the foreign markets have wrecked themselves; our so called modern and efficient business methods have often been ridiculed by our foreign competitors and foreign buyers.

It would seem far better to adapt our methods to suit existing conditions and possibly change gradually their ways to ours than to try, as we have done, to thrust upon them what they do not desire; the mere fact that their customs and ways are different from ours does not prove that theirs are wrong.

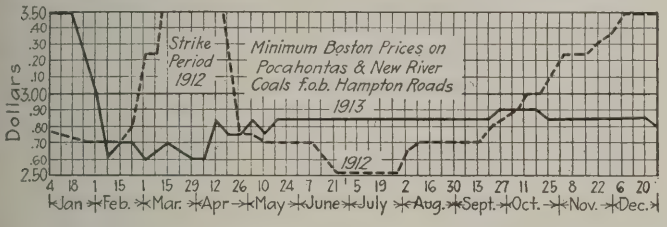
Notwithstanding all this and our past failures, the year 1913 has brought forth enough success to show that the United States coal exporters are in earnest and intend to persevere until their coals become a permanent and growing factor in the world's coal trade.

Marketing and Shipping Conditions on the Atlantic Coast in 1913

By G. G. Wolkins*

SYNOPSIS—The year just closed was distinguished by the highest average prices that ever prevailed; $2.85 was the base price for Pocahontas, New River and Georges Creek, and this remained firm into December. The sustained high level for the better Pennsylvania grades was a striking development of 1913, as well as the increased foothold they secured in this market. A surplus of all kinds of water transportation the last of the year. Anthracite was generally firm and in a satisfactory position. Independents were little heard from the second half-year. The Pennsylvania state tax was a feature of anthracite trade.

Although 1913 early sagged off from the panicky conditions of November and December, 1912, yet in the main it was a satisfactory year. It was particularly so to operators as they netted higher average prices than had ever been obtained before. There was a pronounced labor shortage in most of the districts that somewhat curtailed output; here and there as in the New River field labor difficulties cropped out, and there have been weak spots in the market; but as a whole, the coal trade has enjoyed 12 months of flourishing and remunerative business.



Labor Troubles and Coal Prices

The only conspicuous flare-up was along the Chesapeake & Ohio Ry., centering in the Kanawha and New River districts, but the actual suspension in New River lasted only about five days and some of the mines were not affected. Settlement came through concessions largely on the part of the operators, and July 7 practically all the

*50 Congress St., Boston, Mass.

mine workers were back at their places. Since then a shortage of men has been the rule in West Virginia and in many parts of Pennsylvania, but as it turned out, very little more coal could have been absorbed than was mined, without seriously affecting prices.

Since July 1 the market has largely turned on the output in West Virginia. That was for several weeks a matter of much anxiety with consumers in New England, but at length in September, as advance stocks began to pile up and fears were correspondingly allayed, the scale turned, and late in October it was apparent production would be ample for all needs. Thereafter market conditions were as easy as normally in June and July. Spot coal sold down to the season contract figure through the fall and while several times it seemed as if the $2.85 price was on the point of wobbling, it safely cleared all obstacles and remained firm to the end of December.

It took months, however, for the situation to clear and the market settle down. After February, when the last echoes of the tight winter market had faded away, there was a long spell of dullness. The spot market was less than the announced contract price by quite a margin, but beginning in March a more hopeful spirit took hold and through the rest of the spring there was a firmer, though tempering market. By June some of the large buyers realized they had over-stayed, and there was enough quiet hurrying to cover to lift most of the operators out of the slough and put them in position to command the prices that up to then they had only hoped for. Then came the strike talk in New River and business was plentiful for all grades until well into the fall.

Increased Demand for Pennsylvania Coals

The high average price of the better Pennsylvania grades was a notable feature of 1913. For these coals to command the figures they did, month after month, with no particular shortage of cars, or anything more than threatened upsets in West Virginia, has certainly been a remarkable development. Instances could be multiplied where coals from Clearfield, Somerset and Cambria Counties have made inroads on tonnage that has always been considered "fixed" for Pocahontas and New River. There has been a great light in this respect in New England during the past year. A considerable quantity of these coals of known origin has found its way into the bunkers of off-shore freighters and liners, a thing practically unheard of here except in stress times.

In general, 1913 has helped bring home to consumers some plain facts. It has shown them they must year by year face a constantly mounting fuel cost; it has shown that the very highest grade coals like Pocahontas, New River, and Georges Creek are each year growing more susceptible to an increasing demand for export and for Government use, and that New England must depend more and more upon the quality coals of Pennsylvania. It will be interesting to see the developments along this line in 1914.

From "free coal" in the new tariff there is little help for the New England consumer. Cape Breton coal is the only grade imported to any extent, and it is enough inferior to the better American coals, while mining and trans-shipment are so expensive, that cutting out the 45c. duty is expected to have practically no effect. The use of provincial coals is confined to special cases and no marked change is looked for in that respect.

Pocahontas and New River

The most marked feature of the Pocahontas and New River situation was the remarkable strength shown by the season price of $2.85 f.o.b. Hampton Roads ($1.45 at the mine). For a time in the early spring the prospect was at least doubtful, but in March, when spot prices began to be hammered hard the rival interests got together and tidewater accumulations decreased. Thenceforth the market was held in impressive fashion and 1913 was a banner year so far as returns were concerned.

The year opened with slow loading at the piers and prices firm at $3.50@3.60 f.o.b. and $4.50@4.75 on cars Providence and Boston, but with the actual movement pretty well confined to contract business. Later there developed a receding market, and in late January signs of the new contract season appeared in rumors of a $2.85 price. In 1912 the top season price had been $2.70, and by far most of the tonnage had been closed at $2.50@2.60, so among buyers there was small faith in the stability of the new price. This was emphasized when some of the shippers, pressed with coal, let the spot price down to $2.60 and $2.70, but as March went by and the old contract season ended, the market inspired more confidence. Seasonable weather helped steady prices and gradually it appeared that a volume of inland business had been covered at 15c. over the 1912 basis. But the large corporations were slow entering the market; it was felt conditions did not warrant so sharp an advance, and it was not until the Chesapeake & Ohio labor situation began to be talked about, and restriction became effective, that purchases were made to any extent, and then only with a clause protecting the buyer against a decline.

A Firm Market to the Close of the Year

The recognition granted in the Kanawha district made it seem sure the New River operators must either concede important points or face a more or less serious strike. For several months the issue was in doubt and as usual buyers pretty generally took the worst view of the outlook and made the $2.85 contract figure so firm that by June not only were the agencies comfortably supplied with business, but most of them were so cautious over futures that they declined accepting additional orders for any form of deferred shipment. Certainly for a time there was much apprehension, and it was only after mining was resumed that New England settled down to breathe easier.

Prolonged detention was then the rule at Hampton Roads for several weeks and heavy demurrage bills were paid. Pocahontas output was practically sold up for months to come, and New River was down to 50 per cent. normal; $3.15 was the emergency price. The contract price, therefore, looked sure for the balance of the season and about Aug. 1 there was another, although mild, period of anxiety. It was soon plain, however, that a quiet time would follow and late in August $2.85 was

in view as the spot figure, the agencies that had been shy of taking contracts leading the way.

Demand and supply were well balanced, although most of the coal at tide was applied to old obligations. It was hard to rouse interest, but New England manufacturers continued to drive for deliveries on contract until their stocks were well beyond what they have come to regard the safe point, that is, the utmost they can store.

So with varying prices and an upward tilt once in awhile on spot coal, now to $2.90, now to $3.10, the market went mulling along until in November the larger consumers sought rather to have deliveries postponed, and, taking into account the tonnage of Pennsylvania grades that was taken when Hampton Roads shipments were slow, it was plain New England had absorbed all the advance supply that could be comfortably cared for. Then, too, general business conditions were slackened and consumption had decreased materially. A dull market ensued, "market cargoes" appeared although in a fugitive way, the on-car price at Boston dropped to $3.70, a price that would net $2.70@2.75 f.o.b. Hampton Roads, but the contract price continued to the end of the year without wavering on the part of any important shipper.

Price shading was the exception in 1913, and after March the market had throughout a strong undertone, for even though in the late fall, when things promised to be slack, the export trade came to the relief of the larger agencies and they pulled through in easy shape.

Georges Creek Coals

As in the case of Pocahontas and New River, Georges Creek had a favorable year. The tonnage coastwise was less than in 1912, but the contract price effective Apr. 1 was 15c. in advance of 1912. More than any other grade that reaches this market it is sold on contract and is less subject to the fluctuations of the open market. By far the largest volume of it is placed in transportation owned or controlled by the shippers who are also operators and that is an element in attracting tonnage.

January was a month of slow loading, and few shipments, but into February Georges Creek came down freely on orders. Through the spring it was only intermittently in good supply, for Government colliers last year seemed to play a larger part in Baltimore and Philadelphia loading; $2.85 f.o.b. Baltimore ($1.67 at the mine) was named the net contract price and a comprehensive business was soon taken on. There was some hesitation by large buyers over the differential asked above other noncoking coals, but in this market especially the coal is popular and as it turned out the shippers had all the orders they could manage. In June began a slowing up of deliveries in sympathy with the situation at Norfolk and Newport News, a labor shortage began to be felt, and the district was pushed to keep up with requisitions in hand. Late in July the shippers were far behind on obligations, and only dribbling amounts came through to Philadelphia and New York. Through September and October there was little available at any of the ports, but Nov. 1, Georges Creek, from being the scarcest coal in the market, once more came into adequate supply. The demand was light through November and December and the year closed with only moderate inquiry. So much Pennsylvania coal had been purchased in this section that late in the year Georges Creek for spot sale rather went begging.

The season price was $2.92@3.02 f.o.b. Philadelphia and $3.22@3.32 f.o.b. New York, the year beginning Apr. 1, 1913.

The Pennsylvania Grades

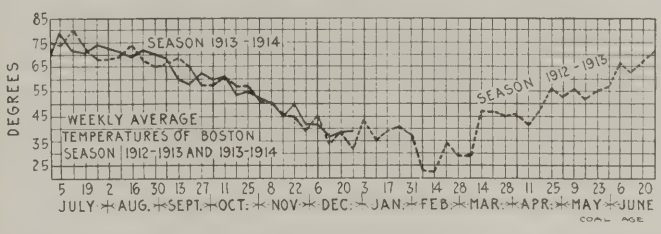
Besides the stronger hold acquired by coals from the Pennsylvania districts on consumers in New England, the increased differential between the better and the inferior grades was another marked development of 1913. They more than held their own, although the extreme caution of Baltimore and Hampton Roads shippers helped to a considerable degree for more than half the year. There are signs that many of the better grades made significant gains in tonnage, and it will be hard for Southern coals to displace them.

The market was more even than has been the rule in recent years. After the slump in late January, the situation was rather slow developing; $1.25 at the mine was a fair price for the less favorably known Clearfields, and from that up to $1.50 was asked on the more popular grades. Generally, 10c. more than in 1912 was quoted for season business, but with an ample car supply and not a particularly encouraging outlook for manufacturing, buyers were slow committing themselves. Soon, however, the 15c. advance at Hampton Roads made a broader demand for Pennsylvanias, and through the spring and summer months there followed a healthy activity for practically all the desirable varieties.

In April most of the high-priced grades had been closed on staple contracts, and thereafter until November there was only a small volume offering from time to time on

spot sales. Many of them were withdrawn from the market and operators put so much dependence on the West Virginia labor complications that up to July they were reluctant to accept orders for deferred delivery. Prices were 5@10c. higher in May than in April, and there was complaint at the slow loading on account of accumulated orders. In June it took no effort to sell all the good Pennsylvania coals that came to tide. A mild stringency appeared and an increasing tendency to decline orders was shown. Cambrias and Somersets touched $1.70, and most operations were under reduced output, the lack being due to small labor difficulties and a general shortage of men. But just as a wide market was opening and the trade was right at the point of buying with not so much regard to quality, the news of the collapse in the New River strike came and the demand in New England sank to more nearly normal. From July on for three months or so there was a moderate market, with now and then a short spurt in response to tight conditions on Pocahontas, New River and Georges Creek, but in the main with prices quite even.

There was still a deal of caution over futures, operators hoping that somehow there would come a turn, but the only turn that came was in November when it appeared that even the producers of the choicest grades were quietly looking for milder business. Unexpectedly enough hand-to-mouth buying developed to tide over, and only in late November and early December did the choicest grades appear in any volume at tidewater points in excess of contract requirements. There was a time in October when inquiry was active for Cambrias and Somersets suitable for bunker use and prices again reached $1.65, but the ordinary low-priced Clearfields were hard to sell at a dollar flat. The Atlantic seaboard was more discriminating than was formerly the case.



Transportation

There was decidedly less fluctuation in water freights in 1913 than for several years past. Except for the 95c.@$1 rate that obtained on large vessels, Hampton Roads to Boston, in January and February and soon sagged off, freights were on a basis of 5c. up from 1912, or 75c. to Boston. A number of season charters were closed at that rate, and it was the exception when a spot schooner or barge got a higher freight after Mar. 1. The tonnage situation was easy thereafter, the latter part of the year showing a surplus of steam as well as sail and barge transportation. Most of the coal to New England is in steamers or over tonnage that is under contract and the current demand was light throughout the year.

The Reading barge rate on bituminous was reduced about Mar. 15 from 90c. to 80c., Philadelphia to Boston, and this rate obtained until Nov. 1, when to most Eastern points the 90c. rate was resumed. On Long Island Sound for New York loading the market has see-sawed from 40@50c. the whole season. The advance of 10c. in October on certain of the anthracite barges, making the rate to Providence 60c. from lower harbor ports instead of 15c., has made it easier for outside boats to command the 50c. rate.

Anthracite

Hard-coal trade on the whole enjoyed a satisfactory year in New England. The mild weather in January and February enabled dealers to get through to the end of the previous season very comfortably, and while in March the market was spotty, April was not at all the disappointment that was predicted. Numerous consignees failed to get the share of minimum-priced coal that they were counting on. The originating companies proved to be well supplied with orders, and some sizes, notably broken and pea, were in relatively short supply. The larger sizes like broken and egg were in many cases put back through the breakers to help meet the tremendously increased demand for stove.

May showed a further shortening up. Receipts were far behind those of April and slow dispatch was the rule at the piers of those companies that have the call for this market. Shipments had begun in April with a rush and buyers feared for a time they would be swamped, but in May there was ample business and enough left over to run the mines full through June. From then on there was a steady demand for the rest of the year, broken and stove especially being the sizes in shortest supply. As early as May orders for broken were declined and the proportion of stove in any one cargo was cut down to such extent that it became embarrassing to dealers who were in no position to take the amount of egg and nut necessary to get their requirements of stove. This situation grew more drastic as the season advanced and in November premiums of 50c. up were offered for cargoes mostly stove.

Individual coals did not continue so important a factor here as was looked for. Low prices were made in February and March to draw business to these coals; at one time in March egg was offered at a discount from the April circular, but sales were only of small tonnages. Dealers for the most part confined their barges to the companies who looked after them during the hard times in 1912. Instances could be multiplied of retailers who placed their April and May orders with certain of the originating companies when they could have saved 15@25c. a ton by buying of independents; the feeling against the shippers of "premium" coal in 1912 was that strong. In early January as high as $7.60 was paid alongside Boston, $1.90 in excess of the circular. Water freights and a stronger demand in other directions soon eliminated all the scattering cargoes through the summer. By fall they had practically disappeared from the market.

Anthracite mines were worked only four days a week during July and August, and this curtailment had the effect of keeping inquiry active through what are ordinarily the dullest months. To the end of December there was hardly a let-up in the urgent call for deliveries all through the fall. Large storage depots in the East were practically bare the whole season. Retail trade was exceptionally good until November when it eased off into a weather market. Boston prices were advanced three times, 25c. each time, until Oct. 2 they were at $8.25 for nut, the 1912 high price for that size. Dealers have held closely to the policy of keeping storage as well filled as possible and those who were far-sighted enough to take extra quantities of stove when such could be had deserve credit for protecting their customers.

New York Market Experiences a Period of Unusual Prosperity

SYNOPSIS—The year was a period of satisfactory business all along the line, but particularly in bituminous. Prices ruled well above prevailing figures of 1912 on both spot and contracts. Anthracite was characterized by an almost year-around shortage of stove coal and heaviness in egg. The new Pennsylvania state tax on hard coal and a readjustment of demurrage rulings in New York Harbor were among the important developments of the year.

Bituminous Market

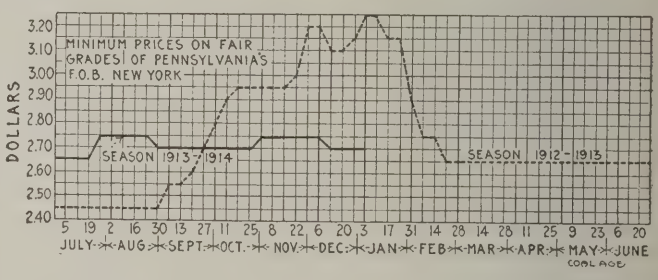
By J. W. Whiteley*

For some years past the bituminous market (barring short periods of abnormal business, due to labor trouble) has been almost continuously weak and prices have ruled at figures which showed little or no profit. The summer months, more especially, showed particularly sluggish conditions. About the only relief was the usual car shortage along in the fall months, which temporarily affected prices; but following the close of navigation on the Lakes quotations usually sagged to somewhere near the summer level.

Cause of the High Price Level

During the winter of 1912-13, however, we ran into an inflated market, prices reaching their highest point about Christmas time and receding thereafter to more nearly normal figures. Some of the large buyers of bituminous have for the last few years become more or less indifferent about closing up contracts, experience showing that they could buy at reasonable figures throughout the year causing a tendency toward laxness in meeting contract obligations. Last winter, however, many of those who had not closed found themselves paying exorbitant prices and as a result this class of buyers learned the wisdom of contracting. This developed a more healthy demand last spring for contract shipment.

There were a number of consumers who did not close at the usual contracting season and later on found it more or less difficult to cover their requirements on a satisfactory grade of fuel. The high prices of last winter furnished an incentive for operators to keep a considerable portion of their tonnage free; in fact some operators made no contracts, feeling that there would be recurrence of the conditions prevailing last year. The fact of their holding aloof undoubtedly had a considerable bearing on the market; it will also be remembered that in the spring of 1913 the Ohio Valley was visited by severe floods which seriously interfered with the operation at the mines. It is estimated in some quarters that the shortage caused by this disaster would run somewhere between 5,000,000 and 10,000,000 tons.



The requirements in the West were unusually heavy, tonnages being closed for Lake shipment at good figures early in the season. The facilities on the Lakes were taxed heavily, and with the large demand in this direction, considerable tonnage of coal tributary to the Eastern market was diverted West. Notwithstanding the generally pessimistic feeling regarding the new legislation on the tariff and the currency question, the coal business at least has been exceptionally heavy, the coal-carrying roads reporting a movement in excess of any former year.

*Whitney & Kemmerer, 143 Liberty St., New York City.

Labor Conditions and the Strong Market

Labor conditions throughout the regions have been a potent factor in the situation. There have been few companies who have had sufficient miners to operate full capacity. While there were no disturbances of any moment in Pennsylvania, the strike in West Virginia fields was serious and of considerable duration. The car supply for a considerable period during the summer months was also short and the combination of these conditions had a noticeable effect on the market.

Perhaps one of the most notable features in the trade during the past year has been the action of quotations on slack. In former years the heavy demand for screened coal, particularly for Western shipment, has resulted in slack being a drug on the market, selling in some cases at less than 25c. at the mines. When compared with $1.10@1.20, which figures were realized this year, it will

be seen just how stiff the situation on slack was; the price was about the same as that asked for run-of-mine.

While indications pointed to a higher bituminous market during the late summer of 1912, the signs of the early fall of the past year were to contrary conditions. The failure of the railroads to secure an advance in freight rates and the increase in wages they were compelled to meet made it necessary for them to practice more or less economy in other directions; as a result orders for steel equipment were consequently smaller. The noticeable decrease in construction in the building trades, in which a considerable amount of iron and steel is used, also had its effect and with the slowing up in this field of endeavor, the demand for cars was naturally less and the production of coke was necessarily reduced.

This served the double purpose of improving the car supply and placing more free coal on the market. The West became over-supplied, and at the close of navigation there was a considerable tonnage available for Eastern shipment. Not only that, but the coal which had been diverted West came back into the Eastern markets. Anticipation of a reduced tariff at about this time and the uncertainty of the proposed currency legislation caused more or less hesitation in the business world. The net result was, of course, a drop in the price of coal.

Sundry Comments

The Pocahontas and New River coals which cover the major portion of the East, from Fall River to Providence around the cape, were maintained at reasonably steady prices throughout the season, and were in short supply from time to time. As a result a considerable tonnage of Pennsylvania coals moved in that direction.

A feature of note in the trade is the gradual education of the bituminous consumer. Buyers are no longer governed by the price alone, but have become quite discriminating. They realize that a difference of 5c. or 10c. per ton on the mine price is, after all, a more or less negligible quantity, more especially when the freight to destination is added. A few cents per ton at destination represents but a small percentage on the delivered price. This trend of conditions is unquestionably advantageous to both the operator and the consumer. The producer feels and knows that by giving his coal the proper preparation and attention it will be appreciated by the consumer and bring a better return. The buyer, on the other hand, gets a better product and is able to select the coal which may be best adapted to his particular requirements.

On the whole, even though the market has taken a considerable slump, the year cannot be considered other than a most satisfactory one for the bituminous trade. Now that the legislation, about which there has been so much apprehension, has become a law, it is believed that after a readjustment to the new conditions has been effected, the business of the country will go ahead again without interruption.

The normal annual increase in the demand for bituminous coal in this country is estimated at about 10 per cent. The increased production for 1913 over 1912 was probably less than the normal increase, which accounts, in a large measure, for the satisfactory returns to the operators. There is no reason to doubt that the demand will show a normal increase with the year 1914, and business should continue for that year on a satisfactory basis.

The Anthracite Market

By G. W. Seiler*

Conditions in anthracite during the past year have been quite satisfactory, both as to output and prices, although it is doubtful whether this year's production will exceed 1911. No comparison can be made with 1912, due to the suspension in mining in the earlier part of that year.

Mining continued throughout the year without any noticeable interruption. Labor troubles occurred during the summer months at some of the collieries controlled by the Lehigh & Wilkes Barre Coal Co. and the Lehigh Coal & Navigation Co., but these disputes were quickly settled.

During January, February and March, the market was overloaded with all sizes of anthracite, due to an exceedingly mild winter. No doubt some of the large profits enjoyed by speculators during the close of 1912 were greatly reduced during the earlier months of 1913, in disposing of high-price coals at low figures. Steam sizes of the poorer grades during this period had an exceptionally hard time in finding prompt disposition.

The Wyoming grades enjoyed a steady output and prices held firm throughout the year. Occasionally a surplus of these good grades in No. 1 and 3 buckwheats would accumulate, but no exceptional difficulty was experienced in moving them where a slight inducement in price was offered.

In the Schuylkill & Lehigh coals, No. 1 buckwheat usually was long and prices sacrificed accordingly. Most shippers from the lower regions avoided shipping large tonnages of No. 3 without specific orders on hand.

The average prices throughout the year on the poorer grades of steam sizes were: No. 1 buckwheat at $2.30; No. 2 buckwheat, $1.85; No. 3 buckwheat, $1.45.

April brought a decided change in conditions; this was naturally expected as the usual deductions from winter prices on the prepared sizes were effective Apr. 1, and also renewal of contracts on steam sizes usually takes place about that time.

The companies issued a circular on Apr. 1 wherein the prices on anthracite were as follows:

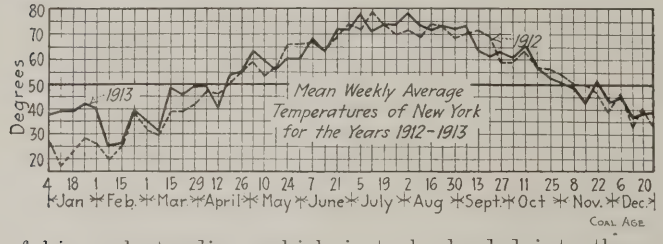
Broken	$4.50	Buckwheat (Wyoming)	$2.75
Egg	4.75	Buckwheat (Schuylkill and Lehigh)	2.50
Stove	4.75	Rice (Schuylkill and Lehigh)	2.00
Nut	5.00	Rice (Wyoming)	2.25
Pea	3.50	Barley (all grades)	1.75

Contract prices on the cheaper grades of barley, particularly Reading coals, were made at $1.50 f.o.b. Port Reading. The regular increase of 10c. each month on prepared sizes from May 1 until Sept. 1 was applied. During April, May and part of June the companies, also individuals, were overloaded on orders for prepared sizes and collieries were working full time during that period.

The Pennsylvania Tax and Heaviness in Egg Coal

On July 1 several of the companies found themselves compelled to charge a state tax of 2½ per cent. on the mine prices of all sizes. This act was evidently accepted as being constitutional because there seems to be no difficulty with the companies in making the dealer pay. The 2½ per cent tax averages an increase of about 10c. on prepared sizes and 5c. on pea size. The operators have not been charging the tax on the junior grades.

During July some difficulty was experienced by the individuals in moving egg and nut sizes, but in most cases a reduction of 10 to 25c. soon relieved the situation. In fact the tremendous demand for stove coal starting in April and continuing up to the middle of December was a great help to the individuals in moving their long sizes. Undoubtedly this unusual demand for stove was brought about by the difference in price between this and nut. In former years nut was usually the popular size in the domestic coals and for that reason an increase in the price of 25c. was made over a year ago.



The disposition of egg size is quite a problem with the operators, as the only time this size seems to move promptly is in the early spring months when the low price prevails or in unusually cold weather. This is probably due to the fact that the largest users of this size are the apartment houses who fill up their bins in the spring months while the coal is not used until cold weather arrives. Unfortunately the collieries cannot avoid making this grade unless egg is broken down into smaller sizes and as that would simply increase the tonnage of steam sizes, it is impractical.

Rail Movement and New Demurrage Rules

All-rail shipments, particularly to Western points *via*

*Sales agent, A. W. Hillebrand Co., No. 1 Broadway, New York City.

the Great Lakes, materially helped in preventing overshipping tidewater points during the period from August up to the close of navigation. Individuals are now adverse to sending any surplus coal to tidewater points, due to the demurrage charges caused by detention at the railroad docks. Since March the Delaware, Lackawanna & Western, the Ontario & Western and Lehigh Valley railroads have added demurrage charges of $1 per car for each day of detention after a free time of five days. Their tariffs also include a clause which most shippers contend is unfair. This provides that if a vessel reports at the coal piers on an order calling for two or three sizes of coal, the shipper is not released from demurrage on any

of his coal standing, which is to be loaded into the reported vessel unless the entire cargo is immediately assembled. This has stirred up quite an agitation among large shippers who propose to bring the matter to an issue before the Interstate Commerce Commission at the next hearing.

The Lehigh Valley R.R. tariff on coal to the Perth Amboy piers does not allow the shippers to stock coal in bins on their piers for an indefinite period, as heretofore unless the shipper agrees to pay demurrage charges on the stocked coal the same as if it were loaded on cars. This ruling is quite a handicap to large shippers. Heretofore the permission to stock coal at the Perth Amboy piers avoided the disposal of individual grades in a crowded market at cut prices. This new ruling has changed conditions in such a way that the individual shippers are confronted with quite a serious situation. Some of the collieries situated on the Lehigh Valley have also other railroad connections, which permit them shipping their products to various points of distribution, and, therefore, are not affected to any large extent.

On the other hand, these new rulings also have their good points as they will do much to prevent an accumulation of large tonnages at the various piers and a consequent general embargo. When an embargo is established at any pier it always has a tendency to break prices as the shipper is forced to either move his coal promptly or shut down until the embargo is removed. Of course, this serious situation does not confront the shipper unless line trade is unusually dull, but a crowded condition at tidewater points is a sure indication that all-rail shipments are lax.

An Easing Up in the Fall

During August considerable tonnage kept moving to all-rail points with the exception of egg coal, and the large companies were compelled to stock this size, while individuals sacrificed at cut prices in order to keep their production moving. September and October brought on the usual stiffening in demand and prices, and during November stove size was selling at premiums ranging from 25 to 50c. above the circular.

On Dec. 1, the state tax was being charged by all the large companies. The unseasonable weather experienced during the last month of the year brought about a heavy slump in the market. Stove coal was easy, and the companies found themselves compelled to stock 10 per cent. of their output. The shutting down of collieries three days per week during the last two weeks of the month helped to give a better tone to the market at the close.

Looking forward to the coming year, there seems to be a general pessimistic feeling among manufacturers that an exceedingly dull period is ahead of them, due to the tariff changes. While there are some in the coal trade that express this same feeling, others seem to be optimistic as to the future. The latter are of the opinion that if the country in general has confidence in the present administration and if business adjusts itself to the new conditions, there is no reason why the coal trade should not have a reasonably good year during 1914.

Connellsville Coke and the Pittsburgh Coal Markets in 1913

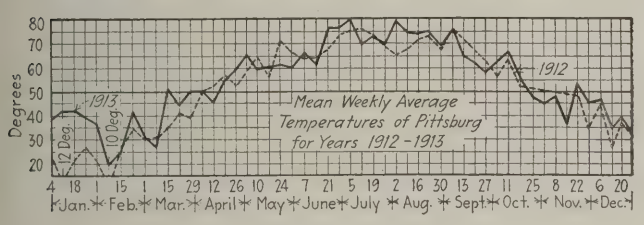
By B. E. V. Luty*

SYNOPSIS—A heavy Lake and manufacturing demand in the Pittsburgh region created an active coal market. Circular prices well maintained, with occasional premiums, until the cessation of Lake shipping. Connellsville coke market fluctuated sharply with prices generally adverse to the operators. Further incursions of byproduct coke noted and many believe that the last of the Connellsville coal will be shipped to byproduct ovens.

The year 1913 was one of heavy coal production in the Pittsburgh district, and in addition the market afforded much more satisfactory prices than the average. Of the two preceding years, 1911 had been poor both as to tonnage and prices, while 1912 was bad as to prices if not tonnage.

Several circumstances combined to make 1913 a good year. The manufacturing demand was exceptionally large, as the industries were prosperous and the iron and steel mills tributary to the Pittsburgh district turned out the largest tonnage in their history. The railroads enjoyed a heavy traffic in the raw materials and finished product of the iron industry, and had a good business in general merchandise. The lake trade was exceptionally heavy, partly because the previous season had left the Northwest with very light stocks, and partly because there was a general expectation that the wage scale settlement for the two years beginning Apr. 1, 1914, would prove an unusually difficult matter, possibly involving a long suspension of mining, with a consequent late opening for lake shipments in 1914.

The Pittsburgh district operators, therefore, enjoyed a



*627 Oliver Bldg., Pittsburgh, Penn.

heavy demand in 1913, which helped to make good prices, but that was not the only factor. The human element entered very largely. For several years the Pittsburgh district operators have felt that coal prices were too low. At the opening of the season quotations would be named predicated upon full operation and a moderate margin of profit, and then it would develop that under curtailed operation, due to lack of demand, and of men, or shortage in car supply, the cost of production would mount. Usually full allowance was not made in advance for the constantly increasing cost of mining due to governmental restrictions and safeguards thrown around mining by the voluntary act of the operators. Before the opening of the selling season for 1913, on Nov. 4, 1912, the Pittsburgh Coal Co. promulgated prices on a basis of $1.30 mine-run. It was then that a new element appeared, for instead of the prices being cut generally in competition for contracts and spot orders, as had almost invariably been the case in immediately preceding years, the circular quotations were quite well maintained, and indeed still higher prices were obtained for a short period toward the close of the lake-shipping season.

Premium Coal and the Fall Recession

Prices were thus in sharp contrast with those in 1912; that year opened with mine-run at $1.15, but after the wage-scale settlement of Mar. 29 an advance was made to $1.22½, covering the 5c. advance in the mining rate, but the market was cut deeper than ever, so that for weeks mine-run was easily obtainable at a dollar a ton.

The 1913 basis was: Slack, 90c.; nut and slack, $1.05;

nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.50; 1¼-in. domestic, $1.55. These were the regular circular prices, with the customary 10c. concession to dealers, making lake coal $1.30. There was some cutting, but very little, and the average realized price on mine-run and lake coal was probably all of $1.25. In August coal began to grow scarce and the condition became rather acute by the beginning of September. Premiums could be obtained, but operators, as a rule, had nothing to spare after meeting contract obligations, and these they did meet as faithfully as physical conditions permitted.

On Oct. 1 a 10c. advance was made, and adhered to as long as there was little coal to sell. Later, demand fell off and the market began to decline. The 10c. advance was quickly lost, and the old prices began to be cut. The end of the lake-shipping season seemed to promise a demoralized market, but the situation was met by a great restriction in output. Monday, Dec. 1, the mines began operating at an average of about 60 per cent. capacity, when during the first 11 months of the year operations had averaged from 80 to 90 per cent. of full rated capacity.

Coal operators have rather studiously avoided making definite statements or predictions regarding the impending settlement of a new wage scale to replace the scale which expires by limitation Mar. 31 next. However, it is quite generally understood that they contemplate a serious contest, if necessary, to shake out much that has accumulated in the scale through several successive settlements in which the men have had things decidedly their own way. Industrial conditions and prospects will, of course, govern to an extent, but it seems certain that the operators will approach the next settlement in a different mood, and with more harmony of action.

Connellsville Coke

There were lively conditions in the Connellsville coke market throughout the year, caused by the earnest effort of a group of operators to secure better prices, relative to the selling price of pig iron, than they had ever obtained before. For many years Connellsville coke had sharp ups and downs. Owing to the practice of making semiannual and annual contracts, based largely upon what chanced to be the spot market at the time, and the spot market of a commodity which is not stocked to any extent is naturally one of wide fluctuations, it has frequently been the case that furnacemen paid high prices for their coke when they were getting low prices for their pig iron, and *vice versa*.

CONNELLSVILLE COKE STATISTICS FOR 1913*

1913 Week Ending	Production: Merchant Production	Production: Furnace Production	Production: Total Production	Shipments: Output: Cars	Shipments: Output: Tons
Jan. 4	156,382	227,822	384,204	11,397	384,831

*From the "Weekly Courier."

At the beginning of 1913 prompt furnace coke was bringing $4 a ton and more, and contracts had been made at various prices ranging up to $3.50. The pig-iron market began to decline at once, and prompt coke fell with it. A group of operators who were allowing the Producers' Coke Co. to act as their selling agent, and had contracts ending June 30, determined that coke for the second half

ought not to sell at less than $2.50. Much other coke was sold at slightly less, but eventually, for July, August and September, the $2.50 operators did succeed in selling a considerable tonnage, month by month, at the $2.50 figure. It became increasingly difficult to get the price and late in the year, when prompt coke was down to $1.75, or possibly $1.70, a $2 price was named for the new year.

Renewed Strength at the Close of the Year

In view of the previous market history, and the great decrease in coke consumption, it seemed rather improbable that the price would be obtained, but in the closing fortnight several sales at the full price were effected, indicating that coke offered at lower figures was limited in quantity or not satisfactory in quality to many consumers. Pig iron was then selling at approximately as low prices as in November, 1911, at which time prompt coke was $1.40@1.45, and six-month contracts were made at $1.55 @1.60. The comparison indicates that while the operators who held to a definite price have been much criticized they really have elevated the level of the coke market.

While pig-iron production, and consequently coke consumption, was somewhat greater in 1913 than in 1912, by about 5 per cent., the production of Connellsville coke was less, owing in part to there being heavier production by other and competitive regions, but chiefly because of greater production of byproduct coke, made at the point of consumption with shipped coal.

The contention of the Connellsville coke operators for a relatively high price, $2@2.50, is based upon a relatively high valuation for the coal acreage. The Connellsville seam has sold at $2000 an acre and more, and producing 7000 tons of coke per acre, carrying enough acreage for a 10- to 20-year life for the operation, this price for coke is necessary. There is the question, of course, whether the coke market should establish the value of the coal seam, or the market value of the coal seam should establish the coke market. With the operators it is a condition rather than a theory, for many of them have bonded their operations on the basis of a high value for the acreage and the bonds must be taken care of if the market can be so conducted as to do so.

In the final outcome the average price of coke and the actual realized value from the acreage will be determined by the rapidity with which consumers adopt byproduct coke. The trend is strongly in that direction, but coke consumption is also on the increase, and as the Connellsville seam has a life of only about 20 years or less, at the present rate of exhaustion, an interesting contest is promised. There are those who predict that the last of the Connellsville coal will be shipped to byproduct ovens, instead of going through beehive ovens at the pit mouth, but the average Connellsville operator will not admit such a probability.

Anthracite Shipments by Lake and the Buffalo Market in 1913

By John W. Chamberlin*

SYNOPSIS—Lake shipments of anthracite break the previous high record by more than a million tons. No important changes occurred in hard coal circles. Bituminous operators experienced a period of unprecedented prosperity, though the year closed with the markets dull. Heavy tonnages were the rule and prices were maintained at an abnormally high level.

Buffalo ships about four-fifths of the anthracite that is handled by lake and has increased shipments during the season of 1913 by nearly one-third. The shipment for the past season is a trifle more than five million tons, net, while the amount for 1912 was 3,925,583 tons and for 1911 it was 3,917,429 tons, this latter being the record up to that time. The cause of the slight increase in 1912 was that the mining suspension in that year cut off the supply till well into June. This means that there is a strong tendency to increase the movements by lake into the Northwest, and the limit is likely to be reached only when the maximum output of anthracite is obtained. At the same time there is a steady increase of shipment from Lake Ontario ports, most of which is confined to that immediate territory.

*90 Johnson Park, Buffalo, N. Y.

The Situation in Anthracite

There has been no important change in the anthracite trade in Buffalo during the past year, either in personnel or equipment. The effort of the Government to dispossess the Delaware, Lackawanna & Western Co. of its shipping trestle at the mouth of Buffalo River, made at various intervals during the past 20 years or more, has again been laid aside temporarily, without apparently arriving at a definite settlement. The Government claims to own the site and also that the mooring of craft at the trestle to load coal is a menace to navigation. The public is divided on the question. There is a move to replace the old wooden shipping trestle with a modern car dump, and one company has about concluded to make the change immediately as these frame structures are expensive to maintain and occupy excessive space.

Water shipments of anthracite for the past season will be divided about as usual among the four companies, Lackawanna, Lehigh Valley, Erie and Philadelphia & Reading. The Ontario & Western did not ship anything by water, as it occasionally does, confining its operations to Oswego. A few cargoes were shipped by Whitney & Kemmerer, who reopened an office in Buffalo more than a year ago.

As to the anthracite trade the outlook is for continued dullness till there is steady winter weather to stimulate buying. At no time during the past year has the consumer been enough concerned about his supply to clamor for immediate delivery. This is due to the fact that there has not been any really cold weather, for an unusually long time, including a great part of last winter. The Buffalo anthracite buyers and sellers now gage the trade by the prices obtained for independent anthracite, of which there is much more on the market since the suspension of the old practice of turning most of it over to the railroads at an accommodation price. When this coal sells at a premium over the regular circular the trade is brisk; it has not done so lately.

ANTHRACITE SHIPMENTS FROM BUFFALO

There has been much disturbance in the anthracite trade since the Pennsylvania tax law was enacted. The companies complied with the law with much reluctance, as they could see the argument of consumers in their effort to escape the payment of what they called the Pennsylvania taxes. At length most of the companies have added it to their bills, though they still appear to hope that it will be nullied by the courts.

The Bituminous Trade

In the local bituminous trade there has been more change and news generally. While this market is mostly a jobbing or an agency one, there are about ten concerns that mine their own coal in the Allegheny Valley and neighboring districts. In 1912 they produced about 4,000,000 tons of coal. The output last year should be considerably more, on account of the great activity of the trade during the summer. There has been no particular change in mine ownership here during the year.

The chief change in the city offices was occasioned by the death of Cyrus H. Polley, who was at the head of the Seneca, Falls Creek and Francis mines, in the Clearfield district or vicinity. The vacancy was filled by the election of Harry Yates as president of the companies, and the appointment of W. M. Campbell, general manager. The retirement of Charles T. Faulkner from the management of the office of the Sterling Coal Co. was followed by the withdrawal of the agency. Mr. Faulkner is now at the head of the Western New York Fuel Co. J. Fred Morlock gave up the agency of W. A. Stone & Co. and organized the Morlock Collieries Co.

A new agency is that of the Baker Coal Co., of Boston, with F. L. White from the Boston office as the northern sales manager. This agency proposes selling the coal mined at the Pine Run and Cobaugh collieries in the Allegheny Valley, of which Mr. Bader is part owner. The output includes considerable cannel coal, which is found along with the bituminous. The consolidation of the offices of the Pittsburgh Coal Co. and the Monongahela Co. gave occasion for the manager of the latter, J. Q. Clark, to organize the Monongahela-Youghiogheny Coal Co.

Bituminous Market Conditions

The bituminous year as a whole has been more active and more prosperous than ever before, in spite of the dullness of the market during December. For some reason, hardly understood by even the oldest member of the trade, the demand continued strong all through the warm months, so that it was difficult to get miners to produce or cars to transport the coal as fast as it was sold. Allegheny Valley operators, who had almost despaired of ever again seeing prosperous days, sold a largely increased output at prices 30c. above the ordinary.

This continued till well into the fall, in spite of the weakness of the iron trade and other industries. Then it was found that the consumers had an overstock of coal, the big shipments to the lakes were cut off at about this same time, while an effort to curtail mining failed. The car shortage, which had controlled the output all summer also disappeared and it became impossible to sell anything like the amount handled during the summer.

Still it would be impossible to cut out all the profits of the summer if nothing at all had been done in December, as coal was still sold at a profit, though a small one. Operators who had not made many contracts were highly pleased to be able to accept the high prices, which were sometimes more than 30c. a ton above the ordinary; mines under contract were pushed to meet their obligations.

When the reaction set in there was a complete reversion to former conditions. As soon as the mines had a surplus to dispose of they sent out their salesmen and called on the jobbers to come to their assistance. The word "demurrage," which had for some months been unknown to the trade, was again a grim specter from which there was no escape, for the mines were not flexible enough to curtail their output promptly, as they should do every fall when the lakes are about to close, no matter what other conditions may be. During December there was much unsold coal on track.

Natural gas is coming rapidly into more general use; this alone about absorbs the natural increase in demand for heat and power and is much more a competitor of coal than Niagara Falls hydroelectric power, though the rates on this latter have been materially reduced during the year by order of the Public Service Commission. Some coal shippers are so careful in looking after what they consider their rights in this field that they voted against the amendment to the state constitution last fall, which proposes to develop water power over the state for general use.

It should be said in closing that figures showing the amount of coal received in Buffalo are not obtainable. Some of the rail shipping interests keep them for the purpose, chiefly of allotting cars to the mines in time of shortage, but they steadily refuse to make them public. A rough estimate of the receipts makes the anthracite 6,000,000 tons, of which all but about 400,000 tons is shipped out again and the bituminous receipts 7,500,000 tons, of which half to two-thirds is reshipped.

The Ohio Coal Markets and Progress in Mining during 1913

By J. W. Lehman*

SYNOPSIS—Ohio production for 1913 showed an increase of about 10 per cent., making a total of 38 million tons. General softness prevailed in the markets during the early part of the period. Situation firmed up at the beginning of the lake season and gradually improved till near the end of the year. Lake business the largest on record. Labor conditions favorable throughout the period.

The year 1913 was a good one in every department of the coal industry in the Buckeye State. Records so far compiled show the production to be greater than in any former year and prices on the whole have been better. Taking it all in all, the year has been satisfactory to producer, shipper and retailer alike, although there was a general slowness at the close which had a depressing effect.

Production in the Various Fields

It will be several months before complete records of the production in 1913 are available, but estimates have been made by attachés of the office of the state mine inspector and others showing a large tonnage in most fields. At any rate every field held its own with the possible exception of some of the smaller districts, while many of the larger ones will show a substantial increase over the previous year. The total production in 1912 was 34,450,104 tons, which was a record breaker up to that time. It is believed the output in 1913 will be at least 10 per cent. more or possibly 38,000,000 tons.

The eastern Ohio district will show up the largest increase over the figures of the previous year. In that section, which includes Belmont, Jefferson and Harrison Counties, a number of new mines were opened and the equipment in others was increased. Thus the production of 9,316,000 tons in Belmont County last year will undoubtedly be advanced to more than 10 million tons and the other counties in the district will show like increases. There was also a good advance in the production in Guernsey County, known as the Cambridge district. Last year that county produced 4,333,966 tons and the total this year will be more than 5,000,000 tons.

In the Hocking Valley the output has been satisfactory for the greater part of the year, but the gain in this district will not be as much as in some other sections. This is accounted for by the abandonment of a number of operations which have been about worked out and the dearth of new mines to make up the loss. The tonnage of 4,886,476 in Athens County will likely be increased to a certain extent, but other counties are not expected to show any gain. The Pomeroy Bend field has been quite prosperous and the tonnage will be equal to if not more than that of the previous year. The production in Meigs County in 1912 was 635,640 tons. Some development work was done during the year in Pomeroy Bend fields principally in electrifying several mines.

The Jackson field is holding up well but there is not much hope for increased production because of the fact that many of the mines are completely worked out. The output in 1912 was 783,334 tons, and it is doubtful if that amount will be reached this year. In the Tuscrawas and Massilon fields there has been fairly active operation during the greater part of the year. The same is true of the Coshocton district, where the output was fair but not as large as in some former years.

Prices and the Car Supply

The price situation was fairly good throughout the year. In December, 1911, prices for domestic lump in the Hocking Valley district ranged around $2, but softness followed early in January, and the circular was reduced to $1.50. It remained at that figure during the spring and early summer when the lake season opened and then July 1, a circular advancing domestic lump to $1.60 was issued, followed by another Aug. 1, to $1.70, and $1.75 was reached by Sept. 1. Finally on Oct. 20 the price was raised to $2, where it remained during the balance of the year.

Other grades of coal generally followed the fluctuations of domestic lump. The various mining districts advanced the prices about the same time as the Hocking Valley. Pomeroy Bend quotations for lump were generally 15c. to 25c. more than those in the Hocking Valley. In eastern Ohio prices also increased, ¾-in. selling around $1.75. Fine coal throughout the year was in good demand and prices ranged high.

The car situation toward the latter part of the summer had the effect of strengthening the market. There was an acute shortage of equipment and deliveries were much delayed as a result. But later on with the coming of mild weather cars became more plentiful and at the close of the year the supply was adequate for all needs.

The Lake Trade

The lake season was one of the most prosperous, if not the best, in the history of the Buckeye State. The tonnage of Ohio coals shipped to the Northwest *via* the lakes was large. The demand for fuel from that section was active during the entire year and lake shippers and dockmen made every effort to get a large tonnage shipped. Little congestion interfered with lake shipments. Vessels were generally plentifully and were kept in service until the close of navigation.

The records of the Toledo docks of the Hocking Valley R.R. show a large increase over last year. The tonnage loaded by the Toledo docks was not all produced in Ohio and thus is not a true index of Ohio business. By districts the tonnage shows an increase in most cases over the records of 1912, as follows:

The Hocking Valley district shipped 750,689 tons in 1913 and 634,260 tons in 1912; the K. & M. district shipped 709,939 tons in 1913 and 590,944 tons in 1912; the C. & O. district shipped 1,010,841 tons in 1913 and 986,092 tons in 1912. The N. & W. district shipped 104,362 tons in 1913 and 72,398 tons in 1912. Reports from other scattering districts show that the Toledo docks

*60 Ruggery Bldg., Columbus, Ohio.

paded 2,613,819 tons in 1913, as compared with 2,288,419 ons in 1912.

A great calamity of the year was the storm on the kes in October. It was one of the worst in the history f lake traffic, and since it occurred before the close of avigation all boats were in service. Half a dozen of the rge freighters besides many smaller craft and a large umber of lives were lost. This caused a great decrease n the lake business as many boats were put out of comission. Shipbuilders along the lakes have received rders for four large 10,000-ton freighters to take the lace of vessels destroyed in the storm.

One of the bad features of the past year was the disstrous floods which swept Ohio from east to west late in Iarch. All of the rivers of the state were overflowed and ntold damage was done. The flood was the worst in the estern part of the state, but some sections in the east, specially those along the Muskingum River were ffected. A number of mines in the Pomeroy Bend district were closed down because of flooding and several n the Hocking Valley were put out of commission.

One of the results of the flood was the demoralization of ailroad traffic in every part of the state. This caused shutdown of most of the mines as the railroads were low in getting communications established. The net esult, outside of damage to mines and retailers, was a serius curtailment in the production.

Eastern Ohio did not fall behind in the lake trade, and he unofficial reports from the large operators show that he tonnage shipped in this business was from 25 to 40 er cent. more than the previous year. The bulk of this onnage was shipped from Cleveland and Lorain, while ome found its way to other lake ports. Dock prices hroughout the year were satisfactory and held up well.

Labor Troubles

Steps were taken during the year to enact legislation vhich was adverse to the interests of operators in the tate. At the session of the Ohio general assembly the Green antiscreen bill was introduced and passed by the senate. Before it reached a final vote in the house of representatives it was sidetracked by the appointment of a commission of five to investigate the method of paying for coal mined. This commission was headed by Judge Crow, of Kenton, and contained several members of the United Mine Workers of America.

After taking evidence from both sides on the controversy and visiting all of the coal fields of the state the commission recommended the passage of five laws which would provide paying for coal mined on the mine-run basis with provisions protecting the operators in most cases. This report will be taken up by the Ohio legislature. It is not assured that a mine-run law will be passed but the indications point that way.

During the year labor troubles were generally scarce. In a few cases several mines were closed down temporarily, but the net result was not noticeable. One of the important incidents along that line was the settlement of the trouble at the Trimble mine of the Hisylvania Coal Co., at Glouster, which had been in progress for about six months.

Preparations are being made for the usual biyearly controversy with miners over the renewal of the wage scale. The present scale expires Apr. 1, and it is believed that the miners will submit new demands asking for an increase. Operators are not disposed to advance the mining rate at this time.

There was some litigation started during the year to separate coal companies from railroad management and several important decisions were rendered. Toward the latter part of the year steps were taken to secure a more equitable freight rate for Ohio producers from the Hocking Valley to Toledo, or other lake ports.

Negotiations were in progress about the middle of the year for the merger of the Lorain Coal & Dock Co. and the Youghiogheny & Ohio Coal Co., but after some bargaining the deal was called off. Both properties are located in the eastern Ohio district.

Hampton Roads Market Strong and Has a Record-Breaking Year

By J. W. Bunting*

SYNOPSIS—Hampton Roads market shares in the general prosperity in the coal industry. Car shortage and labor troubles complicate the situation at various times. Coastwise movement heavy. New dumping records established, the total crossing the million-ton mark several months during the year. British invasion of the New River district.

The year 1913 has been one of the most trying to the coal shippers from Hampton Roads ports, although it has at the same time been one of the most profitable.

During the first few months of the year there was considerable difficulty experienced in getting coal forward from the mines and a number of shippers were forced to pay demurrage on vessels held up waiting for coal. Shippers were hardly over this trouble before some of the mines were idle because of the strike. This, however, lasted only a short time and effected but few of the New River operations.

The demand for coal has been good practically all the year. During the summer and fall there was a scarcity at all piers and this, of course, kept prices up. The largest shippers had great difficulty getting coal to take care of contract tonnage. The railroads attributed the shortage at tidewater during the fall to the fact that a large number of cars which had been sent West with coal for lake shipment had been tied up in the congestion on the Western roads and that great difficulty was experienced in getting them back to the mines. Car troubles during the early fall and winter are one of the greatest difficulties which the shippers at tidewater have to contend with, and this seems to be a yearly occurrence.

With the demand steady prices have also remained good particularly on run-of-mine coal. Prices for the entire

*P. O. Box 872, Norfolk, Va.

year have been on an average of from about $2.85@3 for cargo coal. Bunker rates for the year have been $3.30, and $3.15 for foreign steamers and $3.15 and $3.05 for American owned or operated vessels.

Export shipments were heavy with cargoes moving to several new ports to which American coal has previously been unknown. Outside of the coastwise movement which was largest to Providence and Boston, the Canal Zone will rank perhaps as the best market to which coal has moved from Hampton Roads. Of course, this has been for use on the canal work and when this is completed the demand for coal from this source will be reduced, even should coaling stations be established in that section.

New Dumping Records and Improvements

Records for heavy dumpings have been made at all Hampton Roads piers during some month of the year, the best record made by the Virginian Ry. was at Sewalls Point when it dumped during the month of November a total of 340,769 tons. This fell behind the Norfolk & Western dumpings for that month by only about five thousand tons. The Norfolk & Western Ry., of course, has always led in the monthly tonnage, but for the month of November it experienced a car shortage, which considerably handicapped it; otherwise the Virginian Ry. could not run it so close a race. Several times during the year the monthly movement amounted to over a million tons; in August, when a light movement is naturally expected, the total dumpings amounted to 1,030,434 tons.

Work on the new steel piers of the Chesapeake & Ohio Ry. at Newport News and the Norfolk & Western at Lamberts Point has been progressing all year, and both these piers will be put in operation early in 1914. The Norfolk & Western Ry. has already given its machinery, cars, etc., a test and found everything working satisfactorily. It is only waiting now for some of the minor work to be finished when it will start dumping. It will probably be some months before the Chesapeake & Ohio pier is ready for operation. With these two new piers working, facilities at Hampton Roads will be greatly increased and 1914 should see some further records made by the railroads with terminals at tidewater.

On account of the mild fall and winter the demand for coal for domestic use was comparatively light and retailers are complaining of a generally dull year. Prices for anthracite coal have averaged about $7.75, splint, $5.50@5.75, with Pocahontas and New River steam run-of-mine in small quantities at $4@4.50 per ton.

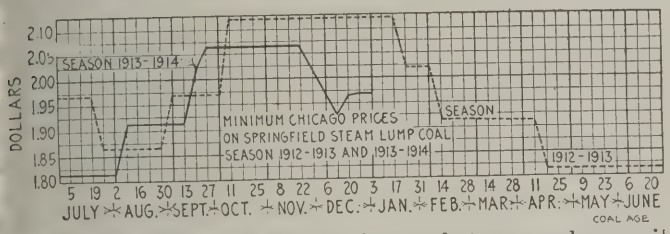
Considerable uneasiness has been felt by some of the smaller selling agencies at tidewater on account of a report to the effect that practically the entire New River coal field had been sold to a British syndicate. The owners of the largest interests have emphatically denied these rumors and stated that while some small operations may have been sold, that the $50,000,000 reported to have been paid for the mines, would not purchase the number mentioned as having been included in the deal.

A new enterprise put into operation in connection with the handling of coal from Hampton Roads is the storage plant recently completed at Sewalls Point. This is expected to take care of over 200,000 tons and should the occasion demand, it could be enlarged with little cost to take care of over half a million tons, with practically the same machinery now in operation there.

While there has been considerable improvement made during the year in the facilities for handling coal, 1913 has gained little credit in the matter of tonnage with these improvements, and it remains for the coming year to show whether the dumpings over the new piers will be increased in proportion to the increased facilities.

The Chicago Market and Trade Conditions in 1913

By Herbert Waters



SYNOPSIS—After passing through a year fraught with many vicissitudes, Chicago coal dealers are looking forward to a greater prospecity in 1914. Few regrets were heard with the passing of the old year; it was a period of erratic prices, and while there were a number of bright spots, the 12 months were not satisfactory. Many features entered into this situation, the most important, perhaps, being unfavorable weather conditions. Prices would be advanced one week only to take a downward course the week succeeding.

The year opened with the Chicago domestic market technically in the weakest position it had occupied for several months. Coal of almost every variety was on track without immediate buyers. Soft weather was one of the chief factors in the situation. Anthracite was in good demand, but the strength of that fuel comprised the entire virility of the market. Springfield domestic lump was selling at $2.32, Franklin County egg at $2.55@2.80, and Clinton screenings from $1.57@1.62.

During the week ending Jan. 11 there was a sharp drop in temperature, which had a beneficial effect upon the market. An abundant supply of coal among dealers, however, prevented the price list from moving upward. Warmer weather soon followed and dealers again complained. Scarcely a branch of the domestic fuel trade escaped the depressing influences. Coke was saved from a bad break because some of the ovens diverted a part of their productive capacity to the making of furnace and foundry coke instead of the crushed variety. In many branches of the coal trade there were cancellations of orders and reductions in prices. Toward the end of the month there was weakness in domestic coal and the demand for steam fuel was far from heavy.

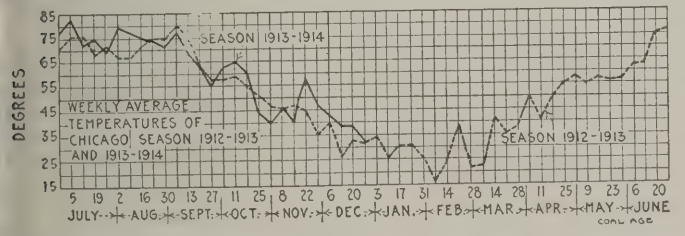
With the advent of February there was a sharp curtailment in production owing to the unfavorable market. Many of the mines in Illinois and Indiana closed down two or three days a week. The price list at this time placed Franklin County domestic lump at from $2.45@2.55, Springfield steam lump at $2.02, Clinton mine-run

t $1.97, and Franklin County screenings at from $1.90@ 2.05. Smokeless lump and egg was quoted at from $3.55 @3.80. Even anthracite coal went begging. Toward the middle of the month colder weather stimulated buying sufficiently to absorb accumulations of unsold coal as well as regular shipments from the mines. A marked reaction soon followed, however, and the market became demoralized on account of warmer weather and unusually heavy shipments. It was a period of easy prices. Springfield coal was cut 15c. a ton and a similar drop occurred in the Indiana varieties. There was a decline in the price of Hocking Valley coal of 25c. a ton.

At the beginning of March the market was as low as it customarily is in June or July. Some operators sold coal at a loss in order to dispose of it. A slight improvement in conditions soon followed, but it was only temporary. Toward the end of the month the floods in Ohio and Indiana tied up mines and transportation with the result that the market for Western coal was tightened.

Prevailing prices at this period were:

Harrisburg quotations were: Domestic lump and egg, $2.40; steam lump, $2.45; mine-run, $2.20; screenings, $1.90@1.95; No. 1 nut, $2.40; No. 2 nut, $2.40; No. 3 nut, $2.30.



Carterville prices were: Lump and egg, $2.40; No. 1 washed, $2.55; No. 2 washed, $2.35.

Coke—Connellsville and Wise County, $6@6.25; byproduct, egg, stove and nut, $4.45; gas house, $4.75@4.85.

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic Lump	$2.07	$2.40	$2.27	
Steam Lump	1.92@1.97		2.17	
Egg		2.40		$3.95
Mine Run	1.87@1.92	2.20@2.30	1.97	3.90
Screenings	1.57@1.62	1.90@1.95	1.67	

Second Quarter

The effect of the disastrous floods in Ohio and Indiana became more noticeable at the beginnig of April through a reduction in the supply of coal and an advance in prices.

Screenings were boosted 10c. a ton. The buying of steam coal at good prices became active soon after with the domestic business unsatisfactory. Activity in contracting developed, buyers showing a strong tendency to strike sharp bargains. At the opening of May contract prices were variable, but the general tone of the market was strong. Early in June a shortage of Eastern coal on contracts caused a stronger demand for the Western product.

Prevailing prices at this time were:

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic lump	$1.97@2.07	$2.55	$2.27	
Steam lump	1.82@1.87		2.07	
Egg		2.55		$3.94@4.30
Mine-run	1.77@1.82	2.20@2.30	1.87	3.30
Screenings	1.62@1.67	1.90@1.95	1.62@1.67	

Harrisburg quotations were: Domestic lump and egg, $2.40; steam lump, $2.30@2.38; mine-run, $2.20@2.25; screenings, $1.90@1.95; No. 1 nut, $2.40; No. 2 nut, $2.40; No. 3 nut, $2.30.

Carterville prices were: Lump and egg, $2.30@2.45; No. 1 washed, $2.45@2.70; No. 2 washed, $2.30@2.40.

Coke—Connellsville and Wise County, $5.25@5.50; byproduct egg and stove, $4.85; byproduct nut, $4.75@4.85; gas house, $4.50@4.60.

Third Quarter

An improvement in the demand for anthracite was noticeable early in July. Domestic call for Western coals, however, was light. Throughout the week ending July 12 the spot market on coal was dull and the steam trade erratic. At this time retail dealers found themselves unable to compete with farmers for labor and were obliged to resort to their own efforts in unloading coal or go without.

The price of almost every kind of domestic coal advanced. Smokeless was selling at a premium of 15c. a ton over the circular, and eastern Kentucky coal was increased to 10@13c. ton. As the end of the month drew near the Chicago steam trade reported better buying as did retail dealers in outlying districts. A wide spread of prices and conditions prevailed.

At the beginning of August, Springfield domestic lump was quoted at $2.07, while that from Franklin County commanded $2.45@2.65. Clinton steam lump was selling at $2.07. The price for Springfield mine-run ranged between $1.82@1.92. Screenings prices were $1.52@1.57 for Springfield, $1.85@1.90 for Franklin County, and $1.52@1.57 for Clinton.

A slow improvement in domestic coal was noted during the opening week of September. Producers asked better prices because the market and the time of year warranted it. Fine coal was under steady pressure. Toward the middle of the month there was greater demand for lump with production below normal. The amount of coal in the hands of retailers was far less than is customary even in the middle of summer.

Within the week ended Sept. 20 there was a perceptible picking up in domestic orders from country districts. The screenings market held reasonably firm, due to a growing belief among operators that they were selling their coal too cheap. Some producers advanced prices for domestic sizes as much as 25c. a ton. At about this time the appointment of receivers for the O'Gara coal properties had a pronounced influence upon the Chicago market. Strife among contending factions tied up various properties and withdrew their productive capacity from the market with the result that the general tone was strengthened.

Prevailing prices at the end of September were:

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic lump	$2.57	$3.05@3.30	$.252	
Steam lump	2.07		2.07	
Egg		3.05@3.30		$4.30@4.45
Mine-run	1.97	2.30	1.87	3.45@3.55
Screenings	1.27@1.32	1.75@1.80	1.22@1.32	

Quotations for Harrisburg coal were: Domestic lump and egg, $3.05; steam lump, $2.65@2.80; mine run, $2.30@2.40; screenings, $1.75@1.80; No. 1 nut, $1.75@1.80; No. 2 nut, $2.55 @2.80.

Carterville prices were: Lump and egg and No. 1 washed, $3.05; No. 2 washed, $2.65.

Coke—Connellsville, $5.50; Wise County, $5.25@5.50; byproduct egg, stove and nut, $4.85; gas house, $4.65@4.75.

Fourth Quarter

The first days of October found the market in better shape than in four years. Starting with anthracite, the strength ran through every grade and size, including

Illinois screenings. Carterville operators, especially, handled a large volume of business. During the week ended Oct. 18 the market continued strong and prices held steady at the top notch. Transportation difficulties were one cause for a stiffening in the market. The movement of Hocking coal was limited to the supply of cars. A cold wave reached Chicago during the closing days of October and aided in giving virility to the price list. Western mines were in a better position than those in Eastern territory so far as the car supply was concerned.

Satisfactory conditions prevailed during the early days of the following month. Springfield domestic lump sold at $2.57 and Franklin County egg at $3.05@3.30. Clinton mine-run was quoted ta $1.87, and smokeless mine-run at $3.45@3.55. During the middle of the month the domestic market softened. There was an advance, however, to $2 a ton at the mines for 1¼-in. Hocking lump, due to the demand for this coal and a shortage of cars. At the end of November the domestic trade was light in all grades of coal. A drop in prices was averted by the action of the railroads in buying heavily for storage purposes.

December was a dull month, owing to mild weather and a continued decline in the manufacturing business. With the closing of factories there was a sharp recession in the steam business, and the anthracite and coke markets were soft.

Prevailing prices at the end of December were:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$2.32	$2.45@2.80	$2.27	
Steam lump	1.97		1.97	
Egg		2.45@2.80		$4.30
Mine-run	1.87	2.30	1.87	3.45
Screenings	1.42	1 75@1.85	1.37	

Harrisburg prices were: Domestic lump and egg, $2.55@2.65; steam lump, $2.25; mine-run, $2.25; screenings, $1.75@1.85; No. 1 nut, $2.55@2.85; No. 2 nut, $2.55.

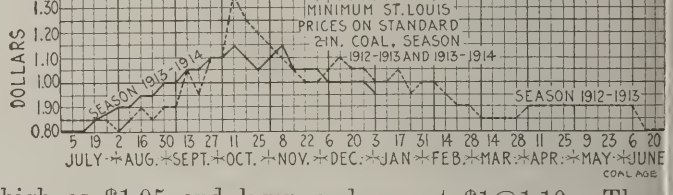
Quotations on Carterville were: Lump, egg and No. 1 washed, $2.55@2.65; No. 2 washed, $2.55.

Coke—Connellsville, $5.25@5.50; Wise County, $5@5.25; byproduct egg, stove and nut, $4.90@5; gas house, $4.75@4.85.

Marketing Conditions in the Mississippi Valley in 1913

By E. J. Wallace*

SYNOPSIS—The St. Louis market continues the one pessimistic section of the National trade. Year has been a lean one due to mild weather and industrial depression. Financial difficulties were more numerous and the big flood aggravated the situation. Keokuk power dam restricted the market for screenings, while competition with outlying nonunion fields is constantly narrowing the range of Illinois coals.



The year opened normal; that is, with such prices as netted the operators a fair margin of profit. Screenings were in demand and sold at what is always considered a good price, 55@65c. for Standard and 75@85c. for Carterville. The screened size market was in good condition, Carterville lump and egg bringing $1.40@1.60, and Standard 2-in. lump about $1.

The Bituminous Market in St. Louis

Warm weather and an extremely mild winter played havoc with business from about the middle of January on. Winter in St. Louis usually begins about Jan. 1, but at no time was there over 2 in. of a snowfall, and while the mercury dropped low enough to make a record, yet it was only for a few days and brought forth no unusual demand.

As the spring months advanced, domestic coal dropped while steam sizes went up and this condition existed well up into the summer months—as late as the middle of August. The year in the coal fields of Illinois has been a disappointment to the most optimistic and a disastrous one to the small operator. About the middle of January mines began shutting down on account of the heavy overproduction. The only cause for profitable prices at any period was the car shortage, and when relief came in this direction there was too much coal and the usual cutting of prices resulted. Far-sighted operators figured that they could keep the mines idle at a lower cost than they could operate and meet competition, and some mines in both the Carterville and Standard fields have not worked since last January.

In April the screenings price went up to around $1 in all fields, while mine-run sold for 70c. and lump at 75c. from the Standard field. Carterville screenings held at as

high as $1.05 and lump and egg at $1@1.10. These conditions lasted until about August, when the scale began to settle the other way, and in October the high price was reached on Standard lump at $1.40 (2-in. size is quoted all through), the screenings went down to 5c. and some were given away for the freight charges. The high Carterville lump price was $2.25, as an average, and the screenings price went down to 20c.

In November a change occurred and the screened-size market began dropping until at the end of the year it was below where it had started. The cause of the poor finish of 1913 as a coal year is laid to the mild open winter of 1912-1913, and the first half of the current season. Only for a few weeks in the fall of 1913 was the car shortage serious in the Illinois fields.

During the latter part of the year there has been a gradual shrinkage in the tonnage of screenings for steam in the St. Louis market and extending north along the Mississippi River, caused by the power furnished from the new dam at Keokuk. The use of the power will continue to grow from this time on.

The past year has been an unsatisfactory one for the majority of the operators in southern Illinois. Many

*Wright Building, St. Louis, Mo.

mines are in the hands of receivers and others are carried by banks that keep them up in the hope that the coming spring will bring more hopeful conditions. From the retailers' standpoint, business has been fair—better on Illinois coals than on other fuels.

Anthracite, Smokeless and Coke

The year opened with Pennsylvania anthracite at a premium of about 25c. over the circular, sometimes more. Such coal as did come in was a sorry disappointment to the consumer, for it was off size and carried a vast amount of impurities. In February the demand fell off and the supply became plentiful. In April prospects opened up good and the retailers started a price war that lasted throughout the year, entailing a loss of from $40,000 to $60,000 that they would have had if the retail circular had been maintained.

Anthracite lost some ground here in the 1912-1913 season, but the price war brought it back again, and this year saw a record movement at times. On the whole the coal was satisfactory, but occasionally large quantities of poorly prepared independent coal showed up.

The year ends with the market in a deplorable condition, caused by jobbers over buying and coal is selling at more than 50c. below the circular, with no demand.

Smokeless coal was at its zenith the early months of the year, on account of the anthracite shortage. It became a popular fuel even at the high price of $5@5.50 wholesale, and as high as $7 retail. While this did not last long, the price kept up well, and there were times during the spring months when smokeless was at a premium. The strike in the smokeless field kept the tonnage down here, and this fuel lost ground. At the end of the year the price for lump and egg was about $4.75@5.

As with other fuels, so with coke, in the early part of the year. The price on byproduct and gas house was from $5.50@6. This market broke early and for the entire year in a general way coke has been plentiful and dropped to as low as $4.50. There has been a persistent effort made during the closing months to keep the price between $4.75 @5, but the supply exceeds the demand and the price drops.

General Conditions

In the industries to which the coal trade looks for the movement of a large tonnage, the past year has not been as prosperous a one as 1912. The lumber business was fairly good the first half of the year, but went to pieces in the summer months for various reasons, the chief of which was the tariff issue.

The lead and zinc mining in southeast Missouri, which industry consumes an enormous tonnage of coal, has been above the average the past year, but no new plants went into operation, and for a short period of time the entire district was idle on account of labor troubles. The iron and steel mills in and around St. Louis have not prospered to the extent that they have in other sections of the country.

Some interesting data on the amount of coal coming into St. Louis were made public at the recent hearing before the Interstate Commerce Commission:

	Tons
Total coal shipped into St. Louis	6,457,683
Delivered on Terminal rail in St. Louis	1,733,278
Delivered by other roads in St. Louis	2,404,105
Delivered for railroad use only	1,136,733
Delivered for points beyond St. Louis	1,183,621

The Terminal Association is paid 20c. a ton, so its earnings on the coal tonnage for the year ending June 30, 1913, were $1,291,536.

Southern Illinois

The increasing wage scale in Illinois will continue to bring a decreasing market. Again, there is ever an overproduction—some mines go bankrupt, etc., but there are always new ones being developed. Seven or eight mines went out of operation in the Williamson-Franklin County field. No new mines were sunk in Williamson County, but three or four new ones were started in Franklin County. In Saline County the floods in the spring put a few mines out of existence, and seriously affected others. The year started off fairly well, but financial difficulties overcame the big operations.

In the Jackson County Big Muddy mines the year was a disappointment, although the fall and winter months proved good ones and some new producing records were established. Perry County suffered a set back in the destruction of the Paradise mine, and other plants found it more economical to stay idle than operate. The Standard field did not improve this year. No new mines were opened and a few old ones were abandoned. The tonnage will drop heavily in this field.

There were no serious mine disasters during the year in southern Illinois. A few mishaps brought about a smaller number of deaths, it is figured, than usual and injuries will fall below the average.

The year was an aggravating one in labor circles. There were many petty grievances and strikes without number. Different locals lost their charters for failure to obey the State United Mine Workers officials.

Milwaukee Market in 1913

By Herman Blyer*

Coal constitutes the leading commodity in the rapidly-growing lake tonnage at Milwaukee. The annual receipts have increased steadily for the past ten years, and have now reached proportions which warrant that city's aspiration to the distinction of being known as the greatest coal-distributing center of the Middle West.

For the ten years previous to 1903 the total receipts of coal at Milwaukee from all sources averaged a little over 1,600,000 tons annually. Since that period the gain has been remarkable. The year 1912 rolled up a total of 5,172,257 tons, which was the highest figure reached up to that time; but the year just closed established a record far beyond this, the receipts by lake and rail being 5,571,-704 tons, or a gain over the year previous of 698,919 tons. The sources of receipt were as follows:

	Tons.
By Lake	5,553,357
By Rail	308,785
Total	5,682,142
†Deduct 90 per cent of carferry receipts	290,438
Actual receipts at Milwaukee yards	5,571,704

†Arrivals by carferry figure in the receipts by lake, but only 10 per cent of this coal is delivered in Milwaukee, the greater proportion going direct to the interior. The receipts by carferry during 1913 aggregated 322,708 tons.

Soft coal makes up the bulk of the receipts at Milwaukee. The average annual shipments of hard coal during the past ten years has been 925,884 tons. The lowest record during that period was made in 1906, when only 756,-

*Milwaukee Press Club, Milwaukee, Wis.

646 tons of anthracite coal were received. During 1908 and 1911 the receipts of hard coal slightly exceeded the million-ton mark. The year 1913, with a tonnage of 1,220,906, established the highest record at Milwaukee thus far.

The gain in shipments was practically all made during the first six months of the year. At the close of that time the total exceeded that of the same last year by over 850,000 tons, due principally to the suspension in mining during 1912. Favorable rates on grain also attracted carriers to the head of the lakes towards the close of the season, and vessels for coal were hard to get. The backwardnes due to this condition was augmented by the disastrous November gale, which swept the Great Lakes and brought the season to a premature close.

Coal moved out to the interior briskly during the spring and summer months, but there was a slowing up in the fall and the season closed with a dull market. As a result all the yards are heavily stocked. The remarkably warm winter thus far has cut down the sales of anthracite coal to a considerable extent, but weather conditions during February and the spring months following may more than make up for the falling off thus far. The future of the soft-coal market will depend largely upon the rapidity and extent of the industrial revival.

Milwaukee, being a manufacturing city, and having several busy suburbs, is a great consumer of soft coal. One large coke and byproduct plant alone absorbs close to a million tons annually.

The wholesale prices f.o.b. cars at Milwaukee as reported by the Lehigh Valley Coal Sales Co., ranged as follows:

Months	Wyoming and Cross Creek Anthracite Egg, Stove and Nut.	Pocohontas Screened	Kentucky Cannel.	Steam Coal Screened Hocking.	Steam Coal Screened Pittsburg.	Mine-run Pocahontas
January.....	$6.75@7.00	$5.50	$6.25	$3.75	$3.75	$3.50
February.....	6.75@7.00	5.50	6.25	3.75	3.75	3.50
March.....	6.75@7.00	5.00	6.25	3.75	3.75	3.50
April.....	6.25@6.50	4.75	6.25	3.55	3.55	3.50

The New Anthracite Rules

SYNOPSIS—The following letter has been sent to anthracite mine superintendents by James E. Roderick, chief of the Department of Mines of Pennsylvania. As the suggestions embodied herein are the result of a conference of inspectors, they should represent a consensus of opinion.

DEPARTMENT OF MINES

Harrisburg, Penn., Dec. 20, 1913.

Mr. ——— ———,

General Manager,

Dear Sir:

You are aware that the Department of Mines through its inspecters has constantly endeavored to reduce accidents in and about the anthracite coal mines, and I am pleased to say that in this work the managers, superintendents and foremen have heartily coöperated; but notwithstanding our united and unremitting efforts, accidents, fatal and otherwise, have occurred with great frequency. Still hopeful, however, that some means might be found by which the lives of the mine workers could be better safeguarded, I called a general meeting of the anthracite inspectors at Wilkes-Barre on Oct. 28 and 29 at which time there was a thorough discussion of the causes of accidents inside and outside the mines. The unanimous opinion was that, to meet the existing conditions, additional safeguards beyond the requirements of the present law must be adopted.

The most prolific causes of accidents inside the mines are falls, cars, blasts, gas, falling into shafts or slopes, suffocation and explosives. During the first 11 months of the present year 510 lives were lost inside the mines as against 463 for the first 11 months of 1912.

If accidents inside the mines are to be reduced, and they should be reduced by one-half, special care and attention must be given to the causes above enumerated. In all mines, but especially in mines where the pitch of the seam is less than 35 deg., accidents from falls must be given the greatest consideration.

Suggested Precautions

I ask you in the interest of the safety of the mine workers to put in practice the following suggestions:

1. *TO REDUCE ACCIDENTS BY FALLS.*

(a) That in addition to the work of the fire bosses or assistant foremen before the employees enter the mine, as provided by law, you will order that two daily inspections of every working place (except in mines where breasts are being worked full) be made by the mine foreman or an assistant mine foreman, one between 7 a.m. and 12 noon, and one between 1 p.m. and 5 p.m., while the men are or ought to be at work.

(b) That each mine shall be divided into districts of suitable size and each district shall be placed in charge of an assistant mine foreman.

(c) That the mine foreman shall each day enter plainly and sign with ink, in a book provided for that purpose, a brief report stating the general conditions as to safety of the portion of the mine examined by him, describing briefly but clearly any dangerous conditions that may have come under his observation and the methods adopted to remove them.

(d) That each assistant mine foreman shall each day enter plainly and sign with ink, in a book provided for that purpose, a report stating the general conditions as to safety of the working places visited in the portion of the mine allotted to him, describing briefly but clearly any dangerous conditions that may have come under his observation and the methods adopted to remove them.

(e) That the mine foreman shall read carefully the daily report of each assistant mine foreman not later than the following day and shall countersign the report with ink.

(f) That the mine foreman and assistant mine foremen on their daily inspection tours shall see that Gen-

eral Rule 12 is being complied with, and in addition see that props are properly placed and fastened securely at top and bottom, so that they cannot be displaced by flying coal unless broken, but if displaced or broken, they shall be replaced before any other work is done.

(g) That the miners be provided with a sufficient number of sawed cap pieces of suitable length, width and thickness.

(h) That the mine foreman and assistant mine foremen in their daily examinations shall insist that the miner remain at work with his laborer in every place where, in their opinion, danger is to be apprehended from falls of roof or coal, and at all times where pillars are being removed.

2. *TO REDUCE ACCIDENTS BY THE CARS.*

(a) That all gangways and main haulage roads driven after Jan. 1, 1914, where employees travel and coal is hauled thereon, shall have a clear space of 2½ ft. from the top rail of the car to the rib, and also to the timber, which shall be made and continued throughout on the same side of the passageway, if, in the judgment of the inspector, the conditions will permit; and all such space shall be kept free from obstructions. However, if it is found impracticable by the inspector to provide such spaces, then safety holes of ample dimensions shall be made on the same side, and not more than 100 ft. apart, which shall be kept clear of obstructions and whitewashed.

(b) That the distance between props and top rails of cars used in breasts shall not be less than 2 ft. and said space shall be kept free from obstructions.

(c) That the height of gangways and traveling-ways wherein employees have to travel into and out of the mines, shall not be less than 5 ft. 6 in. from the top of sill to roof.

(d) That no person under the age of 17 years shall be employed as runner or driver in any mine.

(e) That no person except the driver shall ride on the front end of the car, and no person shall ride between cars, and upon the request of the inspector a seat shall be provided for the driver.

(f) That in slopes where persons are lowered or hoisted, special cars shall be provided for that purpose, the cars to be approved by the inspector of the district.

(g) That in gangways where platforms are used, platforms shall not extend over the top rail of the car.

(h) That where chutes are used they shall not extend more than 12 in. over the top rail of the car, unless they are at least 16 in. above the top rail.

(i) That when a breast is finished or abandoned for over 30 days, all chutes and platforms that may extend over the top rail of the car shall be removed.

3. *TO REDUCE ACCIDENTS BY BLASTS.*

(a) That wherever practicable, all blasts inside the mines shall be exploded by an electric battery.

(b) That all such batteries used shall be approved by the mine foreman, and he shall instruct the miners as to their use, so blasts can be exploded with greater safety.

(c) That only one kind of explosives shall be used in the same hole.

(d) That all shot holes in coal shall be tamped to the mouth.

(e) That a charge of high explosive in coal that has missed fire shall not be withdrawn nor shall the hole be reopened.

4. *TO REDUCE ACCIDENTS FROM EXPLOSIONS OF GAS.*

(a) That the superintendent shall, as far as practicable, see that the provisions of General Rules 4, 5, 6, 7, 8, 9, 10 and 11 are complied with.

(b) That crossheadings between inlet and outlet airways in each split of air when closed permanently shall be substantially shut with walls of concrete, or of stone or brick laid in cement or lime mortar. Provided, however, that the inspector may give written approval of other suitable material in mines with heavy pitches.

(c) That crossheadings between breasts, except those nearest the face, shall be closed, and a brattice from the last crossheading shall be erected so as to conduct the air to the face. Provided, however, that the closing of such crossheadings and the erection of a brattice may be omitted on the written consent of the inspector.

(d) That each breast when finished shall have a crossheading driven at the face to prevent an accumulation of explosive gas.

(e) That every permanent overcast or undercast built hereafter shall be substantially constructed of incombustible material.

(f) That in each mine there shall be telephone connections between the surface and all important parts of the mine, and an attendant shall be on duty at all times at the telephone on the surface.

5. *TO REDUCE ACCIDENTS IN SHAFTS.*

(a) That every shaft and also every slope with an angle of over 35 deg., wherein men are lowered and hoisted, shall have safety gates at the top and also at each intermediate lift thereof, which shall be controlled by cage, gunboat or car.

(b) That where men are lowered or hoisted in such shafts or slopes, a safety device that will prevent overwinding and also control the speed of cage, gunboat or cars at all times shall be attached to the engine.

6. *TO REDUCE ACCIDENTS BY EXPLOSIVES.*

(a) That not more than 5 lb. of high explosive shall be taken into a mine at any one time by any one person, unless more is required for use in that shift.

(b) That high or permissible explosives shall not be sold for use in mines, unless the name of the manufacturer and name and grade of explosives are stamped on each stick.

(c) That detonators shall at all times be kept separate and apart from other explosives until required for use.

(d) That no frozen explosives shall be sold or given to any employee.

(e) That no person shall thaw explosives inside or outside the mines, except by the method recommended by the manufacturer.

(f) That black powder shall not be sold loose in kegs, cases or packages, but shall be sold in cartridges, and shall not be taken into the mine, except in nonconductive receptacles.

(g) That detonators shall be sold in boxes of ten in a box, and not more than one box shall be sold to any one person at one time unless more are necessary for a day's work.

7. *TO PREVENT ACCIDENTS FROM ELECTRICITY.*

(a) That when electric power is used in and about the mines, it shall be cared for in accordance with Article

XI of the Bituminous Mine Act of June 9, 1911, so far as it can be applied to anthracite mines.

8. *GASOLINE AND OIL.*

(a) That six months after Jan. 1, 1914, locomotives using coal, gasoline or oil shall not be used inside of any mine, and the use of gasoline or oil for generating power for any other purpose shall also be prohibited.

9. *TO REDUCE ACCIDENTS BY CARS ON SURFACE.*

(a) That railroad and other cars shall be handled with care.

(b) That safety switches shall be placed above all breakers, so as to safeguard the loaders, and at any other place when requested by the inspector.

10. *TO PREVENT ACCIDENTS FROM SUFFOCATION IN CHUTES.*

(a) That no person shall shovel coal in any pocket until the loader is notified.

(b) That the loader shall not load from any pocket until he is informed that such person or persons are out of the pocket.

11. *RESCUE AND FIRST-AID CORPS SHALL BE ESTABLISHED.*

(a) That rescue and first-aid corps shall be established at each colliery or at each group of collieries, as agreed upon between the superintendent and the inspector.

You are kindly requested to order that the suggestions given in this letter be carried out, as it is the sincere desire of the department, and I know it to be your desire also, to make a record for the year 1914 in the way of reducing accidents in the mines.

The Kemmerer District of Wyoming

Of the three large operating companies in this district the Kemmerer Coal Co. has slowly forged into the lead and is now by far the most important factor in the district. As its name signifies, the company is affiliated with the powerful Kemmerer interest in Pennsylvania.

Unlike most coal districts, operations in the Kemmerer field are confined almost entirely to large corporate interests. Three such are represented in this field: The Union Pacific Coal Co., operating the southernmost extension of the workable coal; the Diamond Coal & Coke Co. controlling the central district and the Kemmerer Coal Co. the northern.

The Kemmerer company is producing about 4000 tons per day, and has a monthly payroll of nearly $90,000; it employs about 1100 men. Development work for the year was confined mostly to their No. 6 mine, although improvements were also made at other of their operations. It is interesting to note that the central-power plant idea is not being neglected in this district. The Kemmerer company is installing a large turbine-driven generator capable of developing 1025 kw., which will be used for pumping at all the mines of the company, some eight or nine miles distant.

The Diamond Coal & Coke Co. operating three mines at Diamondville, Oakley and Glencoe, is the second largest producer in the district. This company is a subsidiary of the Montana copper interests and most of the output is used at the company's mines and smelters at Butte and Anaconda. The Diamond mines are producing about 2200 tons per day, employ between 600 and 700 men and have an average monthly pay roll of about $70,000.

With the exhaustion of the Kemmerer coal, operations are being gradually extended into the lignites lying to the west. There are a large number of these seams, some of enormous thickness, but all of rather a low grade.

Coal and Coke Production in the United States for 1913

The following tables have been compiled largely from data communicated by the several state mine inspectors, estimates having been made only where no such statistics were available, but in all cases upon the basis of reliable information.

PRODUCTION OF COAL IN THE UNITED STATES

States		1912 Short Tons	1913 Short Tons
Bituminous			
Alabama		16,513,040	17,500,000
Alaska		2,000	2,600
Arkansas		2,100,000	2,250,000
Colorado		11,016,948	9,188,432
Idaho		2,000	2,000
Illinois		60,217,019	62,000,000
Indiana		15,285,718	17,246,000
Iowa		6,820,828	7,415,757
Kansas	(a)	6,986,182	7,400,000
Kentucky	(a)	16,490,521	18,500,000
Maryland	(a)	4,964,038	4,800,000
Michigan	(a)	1,206,230	1,400,000
Missouri		4,229,907	4,230,000
Montana		3,048,495	3,365,712
New Mexico	(a)	3,536,824	3,600,000
North Dakota		528,603	495,000
Ohio		34,444,291	37,500,000
Oklahoma		3,600,000	4,000,000
Pennsylvania	(a)	161,865,488	168,000,000
South Dakota	(e)	6,000	(e) 7,000
Tennessee	(a)	6,473,228	6,600,000
Texas	(a)	2,188,612	2,300,000
Utah		3,088,356	3,289,255
Virginia	(a)	7,846,638	8,500,000
Washington		3,346,946	3,677,946
West Virginia	(a)	66,786,687	71,600,000
Wyoming	(a)	7,368,124	(e) 7,100,000
Total bituminous		449,964,723	471,969,702
Anthracite			
Colorado		69,037	51,903
New Mexico		47,892	(e) 48,000
Pennsylvania		84,361,598	90,000,000
Total anthracite		84,478,527	90,099,903
Grand total		534,443,250	562,069,605

PRODUCTION OF COKE IN THE UNITED STATES

States		1912 Short Tons	1913 Short Tons
Alabama		2,881,861	3,500,000
Colorado		972,539	889,989
Georgia	(a)	43,158	45,000
Illinois		1,764,944	1,750,000
Indiana		2,600,050	(e) 2,700,000
Kentucky		196,020	225,000
New Mexico	(a)	413,906	(e) 400,000
Ohio	(a)	388,669	395,000
Oklahoma		.....	.....
Pennsylvania		26,950,081	27,100,000
Tennessee		345,602	328,000
Utah		347,356	314,694
Virginia		1,009,481	1,207,207
Washington		49,000	74,000
West Virginia	(a)	2,465,986	4,000,000
Other states	(d)	2,100,000	(e) 2,400,000
Total		42,528,653	45,328,890

(a) Figures of U. S. Geol. Survey. (b) Year ending June 30. (c) Year ending Sept. 30. (d) Includes output of byproduct coke for Massachusetts, Maryland, Minnesota, Michigan, New York and Wisconsin. (e) Estimated.

The chief difference between the expansive use of air and steam is the heat loss in compression and expansion. Starting with an initial pressure of 75 lb. per sq.in. the adiabatic curve for air cuts the atmospheric line at a point where the final volume is 3¾ times that of the initial volume. The same curve for steam, on the other hand, cuts the atmospheric line at a point where the volume of the expanded steam is 4½ times the original volume. The mean effective pressure, in the case of the expanding air, is 18.9 lb. per sq.in.; while for steam the value of this pressure reaches 25.2 lb. per sq.in. The low value for air is due to the loss of heat during expansion. For this reason air cannot be used expansively to the same extent as steam.

Editorials

New Year Prospects in the Public-Land States

The best gifts the West received this new year were the recommendations of the Secretary of the Interior in his report to the President. We regard these statements as important as if made by the chief executive himself, for the President has been disposed to let the public learn the greater part of the conclusions of himself and his cabinet through the annual reports of the secretaries of the various departments so that only what he considers of leading importance may appear in his own addresses to Congress.

As the President has so far always had his own way with Congress and obtained the passage of such bills as seemed desirable to him, we look upon the recommendations of the Secretary of the Interior as already on their way to enactment and it is well that they should be.

Let us review the situation in the West from the point of view of an ordinary Westerner, who is not a coal operator. We are not sure we have the approval of the Western mine owner in our attitude toward coming legislation. Nor do we much care so long as we are in accord with what is right and fair. Such a position in respect to any coal-mining interest may be credited only with difficulty to the technical press, but we have never been disposed to put purely private interests before those of the nation.

PRODUCTION OF PUBLIC-LAND STATES, 1906-1912

	Tonnage	Value	Price per Ton
1906	25,510,997	$35,711,944	$1.40
1907	27,767,599	44,040,332	1.58
1908	24,819,029	40,254,515	1.62
1909	28,896,787	46,767,383	1.62
1910	32,849,009	53,309,745	1.64
1911	29,675,510	48,404,247	1.63
1912	31,863,762	52,587,127	1.65

The table above shows that the production of coal in the public-land states has increased 25 per cent. in the six years between 1906 and 1912. The bituminous output in all the other states in the Union has increased in the same time 31 per cent. Thus the old well developed partly depleted states of the East have shown greater rapidity of development than the West with its merely grazed resources. Meanwhile British Columbia in the same period of six years increased its production 59 per cent.

Looking at the table we realize the truth of the remark by the statistician of the Geological Survey, E. W. Parker, at the American Mining Congress. He said:

"I desire to call attention to the conditions in the public-land states which are also coal producers. All of them showed favorable comparisons with other states" in earnings on capital.

To relieve the conditions which we have pointed out, Franklin K. Lane, the Secretary of the Interior, suggested in his report that a royalty take the place of a cash payment for lands, and in the case of Alaska that the money earned be thrown into a fund for the development of that territory. There is no reason why this should not be done for the public-land states as well as for Alaska, the royalty collected being paid over, less the cost of administration, to those states to which the production went.

We are afraid that every little while, unless something is done speedily, there will be a revaluation of Western coal lands. Every time some unwise person pays a foolish price for Connellsville, Pocahontas or New River coal, we shall publish it. Mr. Ashley has declared that he reads this record of ours and he will doubtless give his prices a new boost every time he notes a rise if he can find a complacent lawyer-secretary like Walter L. Fisher to give his consent. In a letter dated Dec. 26, 1913, George H. Ashley, the chief of the Coal Section of the Land Classification Board admits that three modifications have been made of the classification system since 1907 and we quote him at length, for it would not be fair to pick and choose from among his statements on that particular subject:

> Public coal lands are classified and valued according to regulations drafted by the Geological Survey and approved by the Secretary of the Interior. The first regulations were promulgated in 1907 and these have been replaced necessarily by those of 1908, 1909 and 1913. The regulations now in effect were approved by Secretary of Interior Fisher in February, 1913, and are given in full in U. S. G. S. Bulletin 537, a copy of which you doubtless have. From the beginning, the principles underlying this scheme of valuation have remained unchanged. That is, the land is valued according to the quantity, quality and accessibility of the coal it contains, accessibility including both depth beneath the surface and nearness of transportation.
>
> The changes that have been made from time to time have to do with the limits set and have resulted in more refinement of detail. Revaluation of lands is always in progress, sometimes with resulting lower price, but more often, because of new data showing more coal to be present than at first supposed, resulting in an increase of price. No widespread or radical revaluations are made, however, and many if not most of the coal lands upon which values have been placed have never been revalued.

There is, we think, no reason why the West should not have advanced like the South, had the land tenure been the same. While the Western production went up 24 per cent., the Kentucky coal output rose 70 per cent. and that of West Virginia 54 per cent.

We saw how British Columbia has forged ahead under favoring laws, advancing between two and three times as fast as the public-land states. The laws of this province, however, are different, according to Donald McKenzie. There, "whether a man is citizen or alien, he can buy a license for $100 good for one year. This license can be renewed for a second and third year upon payment of $100 a year and doing $50 worth of work every 12 months.

"Upon discovery of coal the licensee can have a lease of land for five years at 15c. per acre per year. This lessee can obtain a renewal of his lease for a further term of three years on payment of $100 in addition to 15c. per acre and there is no royalty to be paid for the coal mined. During the term of the lease or within three months thereafter, if the lessee has expended $50 on each 640-acre tract in mining and development work he may pur-

chase the tract for $20 per acre cash and secure his title in fee simple.

"Thus a prospector may secure 640 acres of lands and hold them for three years under a license and prospect them upon the payment of $100 per year and then may procure a lease of the tract for a total of eight years at 15c. per acre, making 11 years before purchase and payment is required.

"During this period any number, not exceeding ten, of the licensees and lessees can combine their locations with locations adjoining, making a total of 6400 acres and may do all their development and annual work upon one claim and at one or more points in the whole tract."

Much of this system of parting with public domain may be open to question but such liberality side by side with the close-fisted narrowness of our land system has shut like a trap on the progress of the public-land states.

But within a year, we trust the restrictions will be removed and the West, released from its financial tyranny, will show a new lease of life, the cause of which perhaps even the citizens of the West may not themselves realize.

Mining Education

The educator is a charming personality swayed rather by the fascination of his studies than by their value to the world at large and as year by year certain subjects receive new interest, the rage to impart them upsets the balance of the educator and he would fain teach them whether they are needed or not.

Years ago, the farmer needed training in agriculture but if we gave him an education, we made him a theologian, a doctor or a soldier, and agriculture which needed entomologists, botanists, agrologists, pomologists or veterinarians was defrauded of her rights.

No one ever questioned whether there was a market for the type of brain culture which was being created, whether the students when graduated were headed where they were needed or to some place already overcrowded. No one even condemned the teachers and parents who coined too many intellects of one character but rather censured the world for refusing to find place for those who had been cultured at so much expense.

And it is so today. The coal companies have at each of their mines place for one or two mine foremen and a few firebosses but some are at much expense, training a great number of men for those few positions. They are creating applicants for jobs, encouraging them to hope they may get them and then they are necessarily disappointing them when the goal seems attained.

But some of the men who qualify will ultimately get the positions they seek and they will then usually get less salary than a hard-working miner can make and so they will not feel that what they have learned at the expense of much evening labor has been adequately rewarded. Thus the generous and enlightened actions of the most advanced coal-mine managers will be largely defeated.

All of which does not condemn education nor declare it of no value, nor advise its denial to the workingman nor mean that he shall never aspire to the highest of places. And what is a workman? It appears to us that he is a man who does his own work and does not merely supervise the labors of others and in a degree, of course, all are workingmen. Among such men are artists, sculptors, writers, educators and surely their work is worth doing well. The workman of whatever kind does not necessarily condemn himself to an insignificant place because he does not seek, at least primarily, to be a boss and control the labors of others.

Certainly there is a place for men who can do their work with consummate skill. The world is full of jobs needing from the workmen the highest of ability. As a matter of fact our motormen today are the poorest possible electrical experts; our mule drivers know little about the needs of the animals they drive; our coal diggers are often merest butchers of coal and the machinemen understand but little of what is needed for the care of their machines and as for our chauffeurs on gasoline locomotives, their ignorance of the motors they run is usually colossal.

We have been so accustomed to these conditions, that they appear normal but if every man were expert and went about his work, whether tracklaying, mining coal or hauling it, with the utmost skill, the product and quality of the work of his hands would immensely increase.

If you have 500 miners, 10 motormen, 20 mule drivers and 15 timber men in your mine, have you prepared to bring out of them an efficiency which will pay them and reward you and make their work a science and a pleasure? Instead, are you not trying to teach them that the height of ambition is to handle a pencil and rule one's fellow man?

It is better indeed to arrange a program of general education than one which will serve only the elect. Colleges are good, but public schools are better, and the coal companies will do well to lay out broadly before their employees the elements of good living and the best methods of performing their duties.

Time was when this was a better country than today with forests uncut, mineral resources untouched, waters unpolluted, and few people to support. Yet the Indian people, who found in that ideal country their abode, starved and shivered in the cold and their misfortunes were so numerous that the population did not increase. Today with a less fortunate country but with a more efficient people, the population is well fed and well housed and their numbers continually increase. The reason is in efficiency. No one can deny that efficient labor is the greatest physical need of the working man and will pay him the most liberal returns.

Let every operator so educate his employees and their families that they can have that efficiency which will make for their well being and will promote their contentment. For there is little pleasure in seeking for jobs which cannot be attained and which even if once possessed, are seen to be far from desirable. And pleasure there *always* is in doing a work of any kind as well as it can be done and giving our service not to the overseer but to the task in which we are engaged.

Training for mine foreman has its proper place, much of it serves as a basis for any kind of mining work and all of it is useful as mental gymnastics which we all need. Such training does, however, urge that there is but one rightful ambition that is to be a foreman having a position of authority and it is, therefore, apt to be unsettling in its effect on mining men in general, if it is the only education which colliery schools afford.

Legal Department

When Does a Labor Union Become an Unlawful Combination?

By A. L. H. Street*

SYNOPSIS—A combination formed by members of a labor union which has the effect of limiting free combination in the production of coal in interstate commerce, is as much violative of the federal anti-trust law as a similar combination between mine operators. Action taken by a union interfering with contracts of employment, are also unlawful and actionable.

Any organized attempt by the members of a labor union, through the means of a boycott, to prevent a coal operator from mining coal intended for transportation beyond the state, or to interfere with traffic in the coal after its delivery in another state, or to prevent persons from negotiating with the operator for the purchase of such fuel in interstate commerce, constitutes a violation of the Sherman law. This conclusion necessarily follows from the recent decision of the United States Circuit Court of Appeals in the Danbury Hatters' case, which latter decision conforms to the judgment of the federal supreme court rendered Feb. 3, 1908, on a former appeal.

The holding in the Hatters' case is that a combination between members of a labor organization to destroy an existing interstate traffic in hats by preventing the manufacturers, by means of a boycott, from manufacturing hats intended for transportation beyond the state, and to prevent the manufacturers' retail customers in other states from further negotiating for the purchase of such hats in interstate commerce, constitutes an unlawful combination within the prohibition of the federal anti-trust act, entitling the complaining manufacturers to recover treble damages for the injury sustained by them in consequence of the combination, even though a small amount of interstate business may be involved.

Prohibits Any Combination That Obstructs Commerce between States

The Supreme Court said that its "conclusion rests on many judgments of this court, to the effect that the act prohibits any combination whatever to secure action which essentially obstructs the free flow of commerce between the states, or restricts in that regard the liberty of a trader to engage in business." (28 Supreme Court Reporter 303.) The cited opinion, also, contains this quotation of Justice Brewer in the case wherein the American Railway Union was enjoined from combining to enforce a boycott by railroads against Pullman cars: "If a state, with its recognized powers of sovereignty, is impotent to obstruct interstate commerce, can it be that any mere voluntary association of individuals within the limits of that state has a power which the state itself does not possess?"

That labor unions are amenable to the anti-trust law says the Circuit Court of Appeals, "is no longer debatable. The law makes no distinction between the classes, employers or employees, corporations or individuals. Rich and poor alike are included in its terms. The Supreme Court particularly points out that, although Congress was frequently importuned to exempt farmers' organizations and labor unions from its provisions, these efforts all failed and the act still remains." The staute looks solely to competition and to the giving of competition full play by making illegal any effort at restriction upon competition. (25 Supreme Court Reporter 276.) It is injury to the public that characterizes interruption of trade as illegal. (Tennessee Supreme Court, 52 Southwestern Reporter 853.)

Application of Principles to Coal Industry

Concrete application of these principles to the coal industry is illustrated by the decisions reached by the United States District Court for the Northern District of West Virginia, in the case of Hitchman Coal & Coke Co. vs. Mitchell, 202 Federal Reporter 512. These points were decided: In their relations to the general public as consumers of the products of labor and capital, the members of labor unions are governed by the same rules of law as to combinations in restraint of trade as are combinations of capital.

Consideration of a labor union is not to be limited to its relations to its members and to those who employ them. A union of mine workers becomes an unlawful combination in restraint of trade, within the meaning of the Anti-Trust law, when it requires its members to surrender their individual freedom of action, or when it seeks to require mine workers to become members whether they desire to do so or not, or when it attempts to restrict or destroy the right of a mine owner to contract with his employees independently of the union, or when it attempts to exclude his right to employ nonunion men, or to discharge any man he sees fit, if that man is not under contract, or when it assumes the right to shut down a mine at any time by ordering a strike, or when it tends to create a monopoly in mine labor, or when it combines with rival operators to restrain the trade of a mine owner operating in another state.

Independently of consideration of the Anti-Trust act, the same court holds that it is an actionable wrong for a labor union to induce its members to break existing contracts with their employers, or to interfere by intimidation or coercion with the inherent right of the employer to control his property and conduct his business in any lawful manner he may choose, and that, although they have the lawful right to advise their members to strike, *unless that amounts to a violation of a contract,* and by reasoning or persuasion to prevent others from taking their places, neither a union nor its members may lawfuly prevent other workers from taking, or remaining in employment, by intimidation or coercion.

The judicial opinions here reviewed reflect the present attitude of most of the appellate courts of the country.

Briquetting in North America

By C. T. Malcolmson*

SCYNOPSIS—More than 40 briquetting plants have been built, but at present only 14 are in operation. Various causes, chief among which is the fact that the difference in price between fine and coarse coal is not sufficient to cover the cost of briquette manufacture, are responsible for this state of affairs.

The history of coal briquetting in the United States is in marked contrast to that of most of our other industries. More than 40 plants have been built, but at the present time only 14 are in operation. There have been various causes for the suspension of some of these plants, the principal one being the fact that in the present condition of the coal market, the difference in price between the fine and lump coal, which was formerly sufficient to cover the briquetting charge and show a profit, has now ceased to exist. Other plants have been designed without practical knowledge of the progress of the art or a realization of what is necessary to make merchantable briquettes.

The largest and most complete coal-briquetting plant in this country is that of the Berwind Fuel Co., at Superior, Wis. This plant started operations in February, 1912. Changes in the design occupied a large part of that season, so that the plant was not placed on a commercial basis until September, 1912. The buildings were designed for the installation of two Rutledge presses; the second press, with the necessary mixing, feeding and drying equipment, was installed during the summer of 1913, which brought the plant up to its full capacity of 80 tons per hour.

During 1913 the plant of the Standard Briquette Fuel Co., at Kansas City, Mo., was completely rebuilt and its capacity increased from 10 to 30 tons per hour. These plants represent the latest development in the briquetting of bituminous coal by the use of American presses, which have been perfected to meet the commercial conditions in this country.

At first, coal briquetting developed more rapidly on the Pacific Coast than elsewhere, owing to the favorable trade conditions which obtained there 10 years ago. At the present time, however, only two plants are operating there; one built by the United Collieries Co., at Seattle, Wash., contains a Belgian or roll type of press, with a capacity of ten tons per hour; and the other built by the Los Angeles Gas & Electric Corporation, utilizing a modified brick press to produce briquettes out of carbonized residue without a binder, at the rate of approximately 15 tons per hour.

Trade conditions have again shifted so that at the present time the opportunities for coal briquetting on the Coast are very encouraging. The Pacific Coast Coal Co. is now building a plant to manufacture bituminous-coal screenings into briquettes at the rate of 30 tons per hour. The plant is similar in design and construction to that used by the Berwind Fuel Co., although the process has been modified to permit the use of California asphalt as a binder.

There are three other plants operating in the Middle West. The Stott Briquet Co., Superior, Wis., make briquettes from anthracite screenings with the addition of a small percentage of bituminous coal. This plant has an output of 12 tons per hour. A roll press is used, with liquid pitch as a binder. Two other presses have been developed for the manufacture of bituminous-coal briquettes to meet American requirements. The Ladley press is installed at the plant of the Indianapolis Pressed Fuel Co., Indianapolis, Ind., with a capacity of 12 tons per hour; the Renfrow press is used at the plant of the Detroit Coalette Fuel Co., Detroit, Mich., having an output of approximately 8 tons per hour. In both plants hard pitch is introduced into the coal in dry form. Advices have been sent out that a plant now being built by the Colorado Pressed Fuel Co., Denver, Colo., will be in operation this year; but so far no commercial briquettes have been manufactured.

The development of the industry in the Eastern States has been marked by the installation of two plants in the anthracite field. The Scranton Anthracite Briquette Co., Dickson City, Penn., employs an improved Belgian type of press having a capacity between 40 and 50 tons per hour. Coal-tar pitch is used as a binder; it is manufactured at the plant and introduced into the coal in liquid form.

The plant of the Lehigh Coal & Navigation Co., at Lansford, Penn., contains two Belgian-type presses with a total capacity of 10 tons per hour, manufacturing briquettes out of anthracite dust and coal-tar pitch by the drp process. Machines of similar design and capacity are installed in the Coal Boulet Co.'s plant, New York City, and the American Coal Boulet Co.'s plant at Phœnix Mines, Maryland.

The plants of the Eggette Coal Co., of Trenton, N. J., and the Virginia Coal Briquetting Co., of Richmond, Va., contain presses of similar design to that installed in the Stott plant and have approximately the same capacity. These two plants, however, use patented binders in the manufacture of their briquettes, in which starch is the main binding constituent.

The plant at Bankhead, Canada, built in 1906, is one of the pioneers in the industry on this continent. This plant now contains two roll presses of a modified Belgian type with a maximum capacity of 30 tons per hour. It operates 20 hours per day during part of the year and has made over 500,000 tons of briquettes. During 1912, 101,175 tons were produced.

The Colonial Coal Co., of Sidney, N. S., has two plants in operation, containing three Belgian presses with a combined rated capacity of 30 tons per hour. The plant at the McKay Colliery, built at North Sidney, N. S., in 1912, has one machine; while at the Bras d'Or Colliery two machines were installed in 1913.

Those desiring the index of Coal Age for the second half of 1913 may send in their names at any time. The index will be ready to mail very shortly.

Discussion By Readers

Longwall Mining Methods

Letter No. 1—Having worked under contract, in longwall mining, in seams varying from 3 ft. to 6 ft. 6 in. in thickness, with and without a drawslate above the coal and under both slate and rock roof, I have used many different methods of working, both in the advancing and retreating systems of longwall. Although I have used three rows of chocks and even four rows along the working face, I have found that the best results are obtained by the use of two rows of chocks only, as shown in Fig. 1. Experience has shown that when three or four rows of chocks are used, the roof is held up too long in the goaf, and excessive weight is thus thrown on the coal face; whereas, when only two rows of chocks are used the roof settles uniformly on the packs, which greatly assists the mining of the coal.

I consider it of great importance to set the chocks in such a manner that they can be easily and safely removed. I have found that the following method gives the best results: Place 3 or 4 in. of fine dirt under the front log, which is laid just back of the road and parallel to the face of the coal. Having laid this first log at the front, build up the back with slate or rock sufficient to support the rear ends of the two side logs, the front ends of which rest on top of the front log. Now, build up the chock to the roof in the usual manner. I have shown this method, in a rough way, in the accompanying figure. It is important to keep the front ends of the chocks in line with the front ends of the packs. These packs are made about 3 yd. in width and are extended as often as the face is advanced sufficiently to permit another row of chocks being built, say about 8 ft.

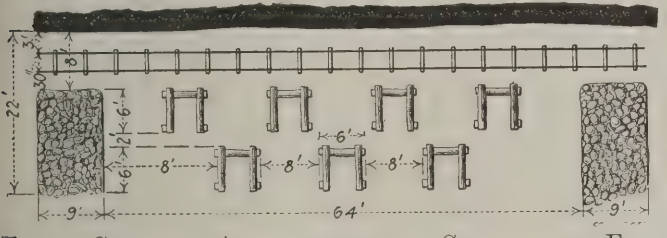

Fig. 1. Showing Arrangement of Chocks and Face Track in Longwall Work

When removing the chocks, the miner always stands in the front and mines out the front log resting on the pile of dirt. When this log is taken out, the two side logs are easily removed, and the other timbers can then be taken out, in turn, from the top down. It will generally be necessary to loosen the slate or rock at the back end with a pick, in order to release the side logs; but the miner need not go behind the chock to do this. This method avoids the use of a back log, the removal of which would give much trouble.

Recently, I had the contract on a longwall face advancing. The coal was 3 ft. 9 in. high, and the contract price was $1.75 per yd., which included blowing down 2 ft. of roof, building the packs and setting and drawing all chocks and post timbers required. The chocks were counted every month to see that none were lost, and when a pack was finished, the company inspector would pull the pieces off the pack to see that no hollow places or timbers were left in the wall.

During three years while working this contract, the only trouble experienced was an occasional fall at the face, or on one of the roads that had been stopped for a few days. In carrying the road along the face, I have used the method shown in Fig. 2, in which case it was necessary to "blow" or "brush" the roof along the face, as shown in the figure; but I consider this method dangerous. Two-piece sets were used, one end of the collar resting in the slate and the other end, at the coal face, resting on a tapered post, as shown in the figure.

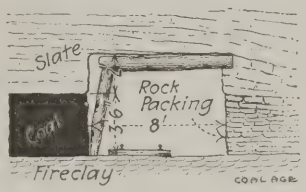

Fig. 2. A Dangerous Method

Charles Waine.

Marianna, Penn.

Letter No. 2—Referring to the mention, Coal Age, Nov. 15, 1913, p. 723, of the working of a seam of coal, in Wales, by the longwall method, which was described by Erskine Ramsey in a paper read before the Alabama Coal Operators' Association, permit me to remark that I believe I helped to open out one of these seams of coal, which was 10 ft. thick.

It was opened at that time by driving entries and rooms. There was no face track as shown on p. 723. In order to support the roof, cribs were built every 4 to 6 ft. apart on each side of the roadways in the rooms and entries and crossbar timber was used to support the roof above the roads. At times, when the first weight would come on, it was necessary to build the cribs to within a foot of the coal face. I do not remember that there was any great caving of the roof.

This system of working was continued for about 12 months and then came a change of management and a change in the system of mining. A face track was laid, as described in the article to which I have referred. As a result of this change, the places were continually caving, and the company estimated their losses to be £125,000 in five years.

Then came another change in the management, and the system of working was changed back to the old entry-and-room system, with no face track. The new company then saved £74,000 the first year; and, in the first nine months of the second year, they had saved £64,000, at which time I left Wales and came to this country. In order to show how it is possible, in Wales, to pack or fill in the space left by taking out the coal in a 10-ft. seam of coal, the conditions in this coalfield should be explained.

In South Wales, there are 16 seams of coal, of which eight are workable, according to Prof. Galloway, in his description of the coalfields of South Wales. It is the

general practice to sink the shafts to the lower measures, and when the workings are sufficiently developed cross-tunnels are driven to tap the other seams. This gives the opportunity to secure enough building material for the 10-ft. seam, by taking it from the other seams that have more than enough for their own needs. A loaded car is taken out of a place and replaced by a car of dirt, and the miner is paid 3d. per car for unloading and packing this dirt in place.

In the case mentioned on p. 723, where the attempt was made to work a 5-ft. 6-in. seam of coal overlaid with an 18-in. drawslate, on the longwall plan, I think too much reliance was placed on the good roof. In changing the system from room-and-pillar to longwall work, in this particular seam, conditions seemed favorable. I would suggest that this should be done by starting to rob the pillars back, after having first secured the face of the coal by building cribs close to the same. As the pillars are drawn back, packs should be built with the drawslate. If there is not sufficient building material to fill the whole of the empty space, the packs should be built on the checker-board system. In starting the longwall face, I believe that a 5-ft. mining is too deep, especially before the first weighting of the roof takes place. A 5-ft. mining gives too much leverage, which will probably break the roof before it can be properly secured after loading out the coal.

In the case mentioned where the 12-ft. skip was taken across the face that had caved, and this was followed by a second cave, I would say that the space was too wide. The roadway should not be over 9 ft. wide, and there should be 5 yd. of packs on the loose end. Then if cribs had been used, every 4 to 6 ft. along this space, I believe there would not have been a second cave. This opinion is based on an experience of several years in longwall work of every kind and 35 years of work in all classes of mines, gaseous and nongaseous.

William James,
Mystic, Iowa. Mine Foreman.

The Certificate Law

Letter No. 10—I have been reading the letter of Joseph Virgin, Coal Age, Dec. 13, 1913, p. 912, in which he states that "a man might successfully manage mines in some of the districts in this state (West Virginia) and yet utterly fail in respect to safety in another state." He refers to some mines having gas, dust, water, bad roof and dangerous quantities of black damp, while other mines may have little of these dangers to contend with or be free from all of them. Mr. Virgin says: "Fancy a man, for instance, who has had charge of mines in the Clearfield region but with no other experience, coming to take charge of the gaseous mines of West Virginia or the mines on the Monongahela, etc."

I gained most of what experience I have in mines in Clearfield County, Penn.—mines that generated as much gas or more than any mine on the Monongahela. I want to say, also, that no mine in the latter district could compare with a mine of which I had charge in Jefferson County, in respect to the generation of gas. I did, however, see and learn much in regard to ventilation while in charge of one mine on the Monongahela. The mine had not been properly planned in the beginning and its proper ventilation was difficult on this account. My experience and that of many other men, at that time, was that many of the mine foremen of the Monongahela mines were as far behind the times in their practical experience as most foremen in other counties and states.

I have been looking over the examination questions asked candidates for the positions of mine foremen and firebosses in the state of Pennsylvania, comparing them with the questions asked in other states, and I want to say that, judging from these questions, any man who has passed the examination in Pennsylvania and has had practical experience in the coal mines in this country or in England, is, in my opinion, able to take charge of any mine either in West Virginia or any other state. My observation convinces me that the examining boards in the bituminous regions of Pennsylvania, for several years past, have arranged the questions for mine foremen and firebosses, so as to cover all manner of mine work.

I fully believe it would be better for all concerned, if every mine foreman, fireboss and mine superintendent was compelled by law to undergo an examination every three years. My reason for this is that ten out of every dozen mine foremen and firebosses who are employed in the mines today, fail to give any time to study or to reading what will keep them in touch with the latest methods of mining work. Many of these men seldom look at a copy of the mining law and cease to read and study after passing the examination and securing a certificate of competency. Many with whom I have talked and whom I have advised to continue to study and to read mining journals, say that they "have not time to read, much less to study"; while others who take mining papers and mining courses lay them aside and devote no time to them, claiming that they "know it all."

I have engaged men who had in their possession first-grade and fireboss certificates, but who did not understand much of the work they had to do. My experience is about the same as that of Mr. Stansberry, in Letter No. 6, p. 913. As he says, these men "could not take a safety lamp apart, clean, fill and put it together again properly." At one time, I had shots fired in the mine by shotfirers, using the wire and the Davy lamp; and when shown how, many of these men could not understand that the gas was so strong at the working face as to make any other method dangerous to employ. It is inexplicable how such men obtain their certificates. I presume it is this sort of men to which Mr. Virgin refers.

A greater interest in the safety and welfare of mining men is being taken today; greater efforts are being made to render the mine immune from accidents of any nature; and more practical methods to secure the safer mining of coal are being insisted upon by all mine inspectors than ever before. It is only reasonable, then, to expect and require that all coal-mine officials shall continue to read, study and increase their knowledge of mining. But, notwithstanding this fact, there are yet a large number of mine officials who think they have all the knowledge they need and continue on in the same old rut. On the other hand, I am glad to say that there are some of the older experienced men who are glad to gain more knowledge themselves, and are striving to educate those in their charge and to assist them in preparing themselves for examinations.

John J. Clark,
Asst. Mine Supt.,
Saginaw, Penn. B. & S. Coal & Coke Co.

The Danger of the Injector

In the Nov. 22 number of Coal Age, on pp. 777 and 778, an article translated from the *Montanistiche Rundschau,* makes an attempt to defend the injector type of mine-rescue apparatus and refers to Dr. John Cadman's paper as having first exploited the danger in the use of the injector. While this may be so in England, I happen to know that it is not true in the United States. J. W. Paul, of the Bureau of Mines, was the first to make this discovery after the death of Farrell, and the details of this accident were given to me by Austin King, of the H. C. Frick Coke Co.

Shortly after this I went to London, and at that time the only man in England who had apparently given the matter any serious attention was Henry A. Fleuss, who, over 30 years ago, invented the first practical self-contained oxygen rescue apparatus. In his effort to improve this, 14 years ago, he discovered the danger from the suction by the injector, and after some experiment dispensed with that device, on account of the danger from accidental leaks.

H. N. Elmer.

1140 Monadnock Block, Chicago, Ill.

Knowing

In looking over the several interesting articles in Coal Age, Nov. 8, my eye caught the "Outcroppings," p. 702, and I read, "Knowing a thing is nothing unless another knows you know it." It is one thing to possess knowledge but quite a different thing to demonstrate that fact to another's satisfaction.

It is a fact that no matter what you know, without you can prove your assertions, your knowledge will be absolutely worthless to you or to anyone else. Again, you may be the *one* person present who knows *how* to do a certain piece of work, and could accomplish better results with the men in your charge, in a given time; but you will not be given a chance to demonstrate that fact unless the manager or superintendent will listen to you and you are able to secure his confidence.

The best mining men sometimes make mistakes, and many do not know what they profess to know; but the man who thinks he knows it all, generally knows the least. To the manager or superintendent, I would say, listen to the man who thinks he knows and give him a chance to demonstrate his ability if he has it and if his plans seem at all practicable. He may be able to save you time and money.

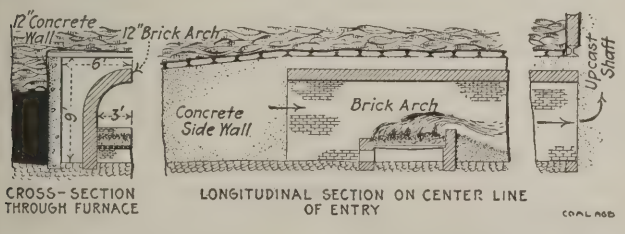
A Knowing Sufferer.

Study Course in Coal Mining

By J. T. Beard

The Coal Age Pocket Book

Furnace Ventilation—When the circulation of air throughout a mine is created and maintained by means of a furnace built in the mine the system is known as "furnace ventilation."



Principle of Furnace Ventilation—The heat of the furnace imparted to the air in the furnace shaft makes it lighter, volume for volume, which causes it to rise in obedience to the law of the equilibrium of fluids. The cooler and heavier outside air, in obedience to the same law, flows into the mine by way of another opening, to take the place of the air displaced. The action is continuous as long as the furnace is in operation. There is thus created and maintained a constant flow of air into and through the mine.

Location of a Mine Furnace—The furnace is built in the main-return airway about 20 or 25 yd. back from the foot of the upcast or furnace shaft, so as to reduce the danger of the fire damaging or destroying the shaft.

Construction of Furnace—The essential details to be considered in the construction of an efficient mine furnace are the following:

1. Beginning, say 50 yd. back from the foot of the shaft, the main-return airway should be gradually widened and its height increased so that the unobstructed sectional area at the furnace will not be less than 25 per cent. greater than that of the original airway.

2. The roof of the enlarged airway should then be secured by steel rails or I beams supported on posts or concrete walls, as illustrated in the accompanying figure, which represents a well built mine furnace.

3. As shown in the figure, both the concrete walls and the brick walls supporting the arch are started on a good firm bottom below the floor line. The thickness of the concrete walls will vary from 10 or 12 in. to 2 ft., depending on depth of cover and other roof conditions. The brick walls and arch will vary in thickness from 8 to 12 in. A good quality of vitrified brick should be used, except where the arch and walls are exposed to the direct action of the flame they should be lined with the best firebrick. All bricks should be first soaked in water before being laid and only the best cement mortar should be used.

The Coal Age Pocket Book

4. The brick walls and arch should be started about 2 yd. in front of the furnace proper and extended to the face of the shaft. The clear width between the walls should equal the width of the fire-grate, and should be such as to leave a clear passageway between the brick and concrete walls. The arch is semicircular and sprung at such a height above the floor as to leave not less than 12 in. of space between the crown of the arch and the rails that support the roof. The purpose of this air space around the furnace is to isolate its heat, which is thus more completely utilized in heating the air current.

5. The area of the grate or the grate surface must be sufficient to burn the weight of coal per hour required to heat the volume of air passing the furnace in that time, to a temperature that will create the air column, in a specified depth and condition of shaft, necessary to circulate such volume of air against a specified mine potential.

The theoretical problem of determining the weight of coal burned per hour, per volume of air circulated, is thus seen to depend on many factors. In ordinary mining practice, however, a safe estimate is to assume that each pound of coal burned per hour will cause a rise in temperature of from 10 to 15 deg. F., per 1000 cu.ft. of air in circulation. Or, calling the weight of coal burned W (lb. per hr.); the volume of air passing Qm (1000 cu.ft. per min.); the rise in temperature t (deg. F.), and the temperature constant c = 10 to 15 deg. F.,

$$W = \frac{Qmt}{c}$$

Example—Find the weight of coal required per hour, to produce a rise of temperature of 360 deg. F., in a furnace shaft when a current of 100,000 cu.ft. of air per minute is passing, under fair mining conditions.

Solution—The weight of coal required is

$$W = \frac{Qmt}{c} = \frac{100 \times 360}{12} = 3000 \text{ lb. per hr.}$$

In very deep or wet shafts or a comparatively small mine resistance, giving a larger air volume and greater loss of heat, the constant 10 deg. should be used; while in dry shafts of less depth, especially if the mine resistance is considerable, a temperature constant of 15 or even 16 may be employed to find the necessary grate area.

6. The grate area necessary to burn any required weight of coal W (lb. per hr.) varies with the hardness and the inflammability of the coal. A mine furnace will commonly burn from 15 to 20 lb. of anthracite, or from 20 to 25 lb. of bituminous coal, per square foot, per hour. Hence the weight of coal required, divided by such constant will give the necessary area of grate surface, in square feet.

Example—What grate area will be required to burn, say 3000 lb. of a very soft, inflammable coal per hour?

Solution—In this case, the coal being a free-burning, inflammable coal, the constant 25 should be used; and the required area is 3000 ÷ 25 = 120 sq.ft.

Inquiries of General Interest

Calculation of Sines and Cosines

Is it possible to calculate the sine and cosine of an angle, as, for example, 42 deg., when no table is at hand?

D. W. SEIGHMAN.

Martin, Penn.

The values of the sines and cosines are for the most part based on geometrical principles, from which trigonometrical formulas have been derived. By the use of these principles and formulas, it is possible to calculate the values of some of the more simply derived angles.

For example, referring to the accompanying Fig. 1, *o* being the center of the quadrant, *oa* is the radius. If

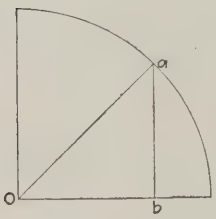


FIG. 1.

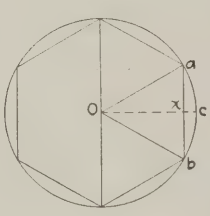

FIG. 2.

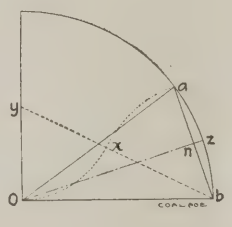

FIG. 3.

this radius, *oa*, bisects the quadrant, the angle *aob* is one-half of 90, or 45 deg. By definition, the sine *ab* is perpendicular to the cosine *ob*, and the angle *oba* is a right angle or 90 deg. Then, since the sum of the interior angles of a triangle is equal to 180 deg., the angle *oab is* 180 — (90 + 45) = 45 deg.; and by the principles of geometry, *ab* is equal to *ob*, or the sine of 45 deg. is equal to the cosine of 45 deg.

All sines and cosines are expressed decimally, the radius of the arc being 1. Then, since the square of the hypotenuse of a right triangle is equal to the sum of the squares of the two sides,

$$(ab)^2 + (ob)^2 = (oa)^2$$

But, since $ob = ab = \sin 45$ deg.; and $oa = 1$, we have

$$2\ sin^2\ 45^\circ = 1$$

and $$sin\ 45\ deg. = \sqrt{\tfrac{1}{2}} = \sqrt{0.5} = 0.7071$$

Therefore, the sine and the cosine of 45 deg. are each 0.7071.

In like manner, by the principles of geometry, a regular hexagon is composed of six equilateral and equiangular triangles. If such a regular hexagon be inscribed in a circle, as shown in Fig. 2, any side *ab* is equal to the radius *oa*, and the angle *aob* is equal to 60 deg. The radius *oc*, bisecting the arc *acb*, also bisects the angle *aob*, and is perpendicular to the chord *ab* at its middle point *x*. Hence, in this case, calling the radius $oa = 1$, $ab = 1$ and $ax = \tfrac{1}{2}\ ab = 0.5$. But the angle *aoc* is 30 deg.; and *ax* is the sine and *ox* the cosine of 30 deg..

Therefore, $$sin\ 30^\circ = 0.5$$

$$cos\ 30^\circ = \sqrt{1^2 - 0.5^2} = \sqrt{0.75} = 0.866$$

Again, the sine of an angle is always the cosine of the complement of that angle, which is 90 deg. minus the angle. Therefore,

$$sin\ 30^\circ = cos\ (90 - 30) = 0.5$$

or,

$$cos\ 60^\circ = 0.5$$

In like manner the cosine of an angle is always the sine of its complement. Therefore,

$$cos\ 30^\circ = sin\ (90 - 30) = 0.866$$

or,

$$sin\ 60^\circ = 0.866$$

Once more, referring to Fig. 3, by the principles of geometry (Euclid, 2, 10), assuming a radius $o\ a = 1$, laying off $o\ y = \tfrac{1}{2}$ and drawing $y\ b$; we have $y\ b = \sqrt{1^2 + \tfrac{1}{2}^2} = \sqrt{1 + \tfrac{1}{4}} = \tfrac{1}{2}\sqrt{5}$.

Then, with *y* as a center and a radius *y o*, describe the arc *o x*. Again, with *b* as a center and a radius *b x*, describe the arc *x a*. Now, draw the cord *a b* and the radius *o z* perpendicular to this cord at its middle point *n*. But, $a\ b = x\ b = y\ b - y\ x$. Hence, $a\ b = \tfrac{1}{2}\sqrt{5} - \tfrac{1}{2} = \tfrac{1}{2}\ (\sqrt{5} - 1)$.

Now, by the principles of geometry, under this construction, the angle $a\ o\ b = 36$ deg.; and the angle $a\ o\ z$ = one-half 36 = 18 deg. But, $a\ n$ = one-half $a\ b = sin$ 18 deg. Therefore,

$$sin\ 18^\circ = \tfrac{1}{4}\ (\sqrt{5} - 1) = 0.30902$$

$$cos\ 18^\circ = \sqrt{1^2 - 0.30902^2} = 0.95106$$

From the three figures that we have given, it is thus possible, by geometrical principles, to calculate exactly the sine and cosine, respectively, of the following angles: 18, 30, 45 and 60 deg.; and observe sin 90° = 1; cos 90 ° = 0. Using these values as the base of calculation, the sines and cosines of other angles that are the sum or the difference of the angles given can be exactly calculated by means of the following trigonometrical formulas:

$$\text{Sin}\ (a + b) = \sin a \cos b + \cos a \sin b$$
$$\text{Sin}\ (a - b) = \sin a \cos b - \cos a \sin b$$
$$\text{Cos}\ (a + b) = \cos a \cos b - \sin a \sin b$$
$$\text{Cos}\ (a - b) = \cos a \cos b + \sin a \sin b$$

The sine and cosine, respectively, of twice or one-half of any angle *A* are given by the formulas

$$sin\ 2\ A = 2\ sin\ A\ cos\ A$$
$$cos\ 2\ A = 1 - 2\ sin^2\ A.$$

$$sin\ \tfrac{1}{2}\ A = \sqrt{\frac{1 - cos\ A}{2}}$$

$$cos\ \tfrac{1}{2}\ A = \sqrt{\frac{1 + cos\ A}{2}}$$

To calculate the sine of 42 deg., proceed as follows:

$$sin\ 15^\circ = sin\ \tfrac{1}{2}\ 30^\circ = \sqrt{\frac{1 - 0.866}{2}} = 0.2588$$

$$\sin 3^\circ = \sin\ (18^\circ - 15^\circ) = 0.3090 \times 0.9659 - 0.95106 \times 0.2588 = 0.0523$$

$$\text{Sin}\ 42^\circ = \sin\ (45^\circ - 3^\circ) = 0.7071 \times 0.9986 - 0.7071 \times 0.0523 = 0.6691$$

Examination Questions

Mine Inspectors' Examination, Held at Springfield, Ill., Dec. 15, 1913

(*Selected Questions*)

Ques.—If 20,000 cu.ft. of air pass in a circular airway 12 ft. in diameter, what quantity of air will pass in one 6 ft. in diameter?

Ans.—The question probably means to ask what quantity of air will pass, assuming the *velocity* of the air current remains unchanged. For a constant velocity, the quantity of air passing will vary as the area or as the square of the diameter. In that case, the quantity ratio is equal to the square of the diameter ratio. Thus,

$$\frac{x}{20{,}000} = \left(\frac{6}{12}\right)^2 = \left(\frac{1}{2}\right)^2 = \frac{1}{4}$$

$$x = \frac{20{,}000}{4} = 5000 \; cu.ft. \; per \; min.$$

This question can also be answered by assuming a constant ventilating pressure, in which case the quantity ratio is equal to the square root of the fifth power of the diameter ratio; or,

$$\frac{x}{20{,}000} = \sqrt{\left(\frac{1}{2}\right)^5} = \sqrt{\frac{1}{32}} = \sqrt{0.03125} = 0.1767$$

$$x = 20{,}000 \times 0.1767 = 3534 \; cu.ft. \; per \; min.$$

Again, it may be assumed that the power on the air is constant, in which case the quantity ratio is equal to the cube root of the fifth power of the diameter ratio; or

$$\frac{x}{20{,}000} = \sqrt[3]{0.03125} = 0.3150$$

$$x = 20{,}000 \times 0.3150 = 6300 \; cu.ft. \; per \; min.$$

Ques.—An entry in a mine is driven N 40 deg. E and the rooms are turned N 10 deg. W. If the pillars are 30 ft. wide and the rooms 24 ft. wide, what is the distance between room centers, measured on the entry?

Ans.—The distance between room centers measured square across the rooms is 30 + 24 = 54 ft. The corresponding distance measured on the entry is found by dividing the distance measured across the rooms by the sine of the angle the rooms make with the entry. Since the entry bears 40 deg. to the east of north and the rooms bear 10 deg. to the west of north, the angle between the rooms and the entry is 40 + 10 = 50 deg. Then, the distance between room centers, measured on the entry, is

$$d = \frac{54}{sin \; 50^\circ} = \frac{54}{0.766} = 70.5 \; ft.$$

Ques.—If 30,000 cu.ft. of air enters a shaft 14 ft. in diameter, at a temperature of 60 deg. F., what diameter of upcast is necessary to pass the same weight of air, at the same velocity, the temperature of the upcast being 90 deg. F.?

Ans.—For the same weight of air and velocity of the air current, the sectional area of the shaft must increase in proportion to the expanded volume of the air current, which is in the ratio of the absolute temperatures of the downcast and upcast shafts. But, since the diameter varies as the square root of the area, the diameter ratio is equal to the square root of the area ratio or the absolute-temperature ratio. Therefore,

$$\frac{x}{14} = \sqrt{\frac{460 + 90}{460 + 60}} = \sqrt{\frac{550}{520}} = \sqrt{1.0577} = 1.028$$

$$x = 14 \times 1.028 = 14.39 \; ft.$$

Ques.—What horsepower would an engine exert when yielding 60 per cent. of duty, to move 100,000 cu.ft. of air per minute, the water gage standing at 1 in.?

Ans.—The effective horsepower or the horsepower on the air, in this case, is

$$H = \frac{Qp}{33{,}000} = \frac{100{,}000 \; (1 \times 5.2)}{33{,}000} = 15.757 \; hp.$$

The gross horsepower of the engine is then 15.757 ÷ 0.60 = 26.26 hp.

Ques.—We have a tank full of water in the morning when commencing work and no more water in sight, as the well is dry. The tank is a circular one 12 ft. in diameter at the top, 14 ft. at the bottom and 18 ft. deep. How long will we be able to run, using 1200 hp.?

Ans.—This tank being a frustum of a cone, its volume is calculated thus:

$$vol. = 0.7854 \frac{h}{3} \frac{D^3 - d^3}{D - d} = 0.7854 \times \frac{18}{3} \times \frac{14^3 - 12^3}{14 - 12}$$

$$= 0.7854 \times 6 \times \frac{2744 - 1728}{14 - 12} = \frac{0.7854 \times 6 \times 1016}{2}$$

$$= 2394 \; cu.ft., \; nearly$$

It is usual practice to estimate the consumption of water as 35 lb. standard per horsepower per hour; which gives in this case 1200 × 35 = 42,000 lb. per hr. Taking the weight of water as 62.5 lb. per cu.ft., the quantity of water used per hour is 42,000 ÷ 62.5 = 672 cu.ft. per hr. The length of time this tank full of water will last is, then, 2394 ÷ 672 = 5.56 hr., say 5 hr. 30 min.

Ques.—What load will break a white-oak timber 8x12 in. and 15 ft. between the supports, if the load is equally distributed along the length of the beam?

Ans.—For a beam supported at both ends, and uniformly loaded, the breaking load is calculated by the formula

$$L = \frac{4}{3} \frac{fbd^2}{l}$$

the dimensions all being expressed in inches, and the breaking load estimated in pounds. Substituting values in this formula as follows: Unit stress, white oak, f = 8500 lb. per sq.in.; breadth of beam, b = 8 in.; depth of beam, d = 12 in.; length of beam, l = 15 × 12 = 180 in.; we have

$$L = \frac{4}{3} \times \frac{8500 \times 8 \times 12^2}{180} = 72{,}533 \; lb.$$

$$L = \frac{72{,}533}{2000} = say \; 36\tfrac{1}{4} \; tons$$

Coal and Coke News

Washington, D. C.

Although the Congressional investigating committee charged with the duty of reporting on the conditions of the mining strike in West Virginia has not yet made ready its report for publication. Senator William E. Borah, of Idaho has completed a statement on the subject embodying his own views which he has just made public. Senator Borah takes a strong attitude in opposition to the action of the State of West Virginia and of the coal mine owners in that region.

He finds that martial law was declared in the Paint and Cabin Creek region about Sept. 2, 1912 and continued in force except at short intervals until June 1913. During this time various individuals were arrested, tried and convicted for alleged offenses, upon orders issued by the military authorities and not by virtue of any warrant issued by the civil authorities or from established courts.

These parties were put upon trial, he asserts, without the finding of any indictment by the Grand Jury before a court martial created by the order of the Commander in Chief, while the charges made against them were in the nature of specifications drawn up and presented by the military authorities. Continuing Mr. Borah says:

In the trial of these parties and in the assessing of punishments, the court before which they were tried deemed itself bound alone by the orders of the Commander in Chief, the Governor of the State and in no respect bound to observe the Constitution of the United States or the constitution or statutes of the State of West Virginia relative to the trial and punishment of parties charged with crime.

At the time these arrests were made and the trials and convictions had, the civil courts were open, holding their terms as usual, disposing of cases and dispensing justice, in the usual and ordinary manner. In rendering judgment and assessing the punishment, the parties were punished by terms of imprisonment unknown to the statutes or in excess of the punishment provided for such offenses under the laws of the state. . . . A number of these parties were sent to jail and many to the State Penitentiary under sentence of this court martial as approved by the Government.

Most of those who were sent to the Penitentiary were given a conditional pardon before the term for which they were sentenced had expired, the pardon being conditional in a general way upon good behaviour. . . . No threats of violence or use of force was made or had against the judges or the courts at any time during the existence of the disturbance or the reign of martial law. . . . . Great feeling and interest doubtless prevailed generally throughout the country, but the existence of this feeling and its effect upon grand or petit juries were not tested by the calling of a Grand Jury, or the submitting of the charges against those persons to a Grand Jury, and no attempt was made to try them before a petit jury—the officers of the county, after the declaration of martial law proceeding upon the assumption that the feeling and prejudice were so strong as to prevent the operation of the civil authorities, together with a further belief that the declaration of martial law had the effect of suspending and nullifying all constitutional and statutory rights of the accused.

It had been expected that Senator Borah's report would be strongly critical of the mine owners and the belief is that although his report is not officially sanctioned by the committee, he being a minority member, that it will be a part of the majority's report, which however, is expected to go considerably further in direct condemnation of the mine owning interests than did the senator from Idaho.

Investigations to Be Made

The United States Committee on Industrial Relations has voted to carry on a direct investigation on the spot in the Calumet copper region and in the Colorado coal mining region, for the purpose of ascertaining the nature of the conditions prevailing in those two parts of the country where aggravated mining controversies have been in progress.

This action on the part of the Committee has been loudly called for during the past few weeks in both Houses of Congress, it being claimed that such an investigation should properly be undertaken by the Committee in question, in order that the facts as to the merits of the strike in each place may be definitely known.

It has been alleged that the action of members of Congress in thus demanding such an investigation was certainly to be regarded as a severe reflection upon the Department of Labor to which would naturally fall, as in the past, the duty of investigating such disorders and if possible offering arbitration or mediation with reference thereto.

The Department of Labor under its present head has been reluctant to do any thing of the kind and has almost refused to do anything that might seem to involve a possible criticism of or difference of opinion with organized labor in the United States.

The present head of this department has at various times announced himself as a confirmed trade unionist, asserting that his opinions on that subject remained the same as in the past—a position which has greatly tended to weaken him with employers who have regarded the arbitration function as one which was properly to be carried on by a non-partisan investigator.

The findings of the industrial commission will not be likely to be made known for a good while to come as the fieldwork is expected to occupy special agents for a considerable time.

PENNSYLVANIA

Anthracite

Wilkes-Barre—While taking measurements in the Maltby mine of the Lehigh Valley Coal Co. recently, two firebosses and a mine foreman were severely burned by an explosion of gas, and for three hours after the accident were entombed in the mine because the ropes had been taken from the cage by a force of men who were making repairs. Rescuers, by walking several miles in a roundabout way, finally reached the injured men.

Catasauqua—The Lehigh Coal & Navigation Co. recently issued a notice to the effect that part of the Lehigh Canal from Coalport to Catasauqua would be abandoned after Apr. 1. After that date coal will be carried between Coalport and Catasauqua over the new branch of the Lehigh and New England R.R.

Scranton—Offending coal companies here are being hedged about on all sides. Recently the city of Scranton again officially entered the list of the complainants against the promiscuous mining of coal in a manner that places the surface in jeopardy. The bill in question explains that the general manager of the Scranton Coal Co. recently served notice on a number of property owners explaining that the pillars will shortly be removed from under their homes.

Harrisburg—Under a ruling recently issued by Auditor General Powell, anthracite coal companies will be exempted from paying tonnage tax on the coal used in the operation of the collieries, but that dredged from rivers and streams is taxable. Every operator is required to furnish the auditor general during the month of January the number of tons mined during the preceding year. If he intentionally refuses or fails to furnish the information he can be prosecuted and, on conviction, be fined not more than $500, or imprisoned not more than one year; or fined and imprisoned in the discretion of the court.

Bituminus

Connellsville—The Connellsville and lower Connellsville coke region during the year 1913 shipped in the aggregate 20,097,901 tons of coke valued at $59,288,808, the average price of all merchant coke being $2.95 a ton. The year 1912 was beaten for quantity and quality, the cash returns being 55% in excess of that received during the previous year. In both quantity and value, however, the business in 1906 and 1907 was close to that of 1913.

Johnstown—The call for the next biennial convention of the delegates from all the locals in District No. 2 of the United Mine Workers of America was issued Jan. 7. It is understood that the convention will be held in Du Bois, on Feb. 24. The scale committee will be ready to begin work on Mar. 1, and the operators will be notified that if they propose taking part in a joint conference again they must have their committee ready for deliberation by that date.

Punxsutawney—The year just closed was one of the most prosperous in the history of Jefferson and Indiana Counties, so far as mining was concerned. The mines have worked throughout the year and allied industries have been correspondingly busy. Except for an occasional strike the miners have worked almost without interruption since Jan. 1, 1913, and the prospects for a continuance of excellent business are good.

Pittsburgh—The annual report of mine inspectors will indicate an increased output during 1913 in almost all local districts. More accidents have occurred, however. In spite of safety and first-aid work, more miners were killed than in 1912, but more were employed than for many years, although this number was insufficient. The coal markets were lively, due in part to floods in the early spring.

WEST VIRGINIA

Charleston—It is believed that all the contracts in the $50,000,000 New River coal deal will have been printed, properly signed and sealed, and copies filed with one of the Charleston banks in a short time. The representatives of the London syndicate will then sail with copies for England, with the purpose of arranging for the first payment of $1,500,000 in February.

Wheeling—The coal mines of this state and the Ohio subdistricts are averaging at present about two days' work per week. Many of the operations are shut down entirely and most of those working are on only about half time. This apathy is explained by the lack of orders, which is an annual affair occurring about this time of year.

Fairmont—The Consolidation Coal Co. completed the past year with a production of about 11,000,000 tons, or 800,000 tons more than was secured in 1912. Every ton of this fuel was marketed at prices higher than those received a year ago. It is estimated that the production would have been at least one million tons greater had it not been for the floods in the Central West last spring, which paralyzed railroad traffic for nearly a month and prevented shipment to that territory.

Bluefield—The shop and drum house of the Borderland Coal Co. were totally destroyed by fire recently. In addition to the buildings, all tools, electric motors, and other valuable equipment were destroyed and considerable damage done to tracks leading to the mine. The origin of the fire is unknown.

KENTUCKY

Lexington—The Kentucky Utilities Co., which is said to be controlled by the Insull interests of Chicago, and which has acquired a large number of electric plants in central and southeastern Kentucky during the past year, recently took over a plant at Harlan, Ky., in the heart of the Harlan County coal-field. The plant is a small one at present, but is destined to form one of a chain of power plants operated by the company in the coal field referred to. The company is now constructing a trunk line for the distribution of current from its central plant at Pocket, Va., and the Harlan, Varilla, Pineville and other plants now owned by the company will form important factors in the development of the coal fields in that section, in connection with the power from the Virginia plant.

Middlesboro—The Low Ash Coal Co., a West Virginia corporation which a few months ago purchased the old Mary Moore mines near Middlesboro, has completed the installation of new machinery at the mine and begun the shipment of coal. The Barner seam is mined on the property. The company has a capital stock of $20,000, and was recently incorporated.

OHIO

Columbus—Arch Grossman, who represented the New York Coal Company, of Columbus, Ohio in Indiana territory for a number of years has resigned to open a jobbing business in Indianapolis under the name of the Cedar Creek Coal Co.

New Lexington—The Blue Rock Run Coal Co. has started work on a new mine on the Olden Farm in Harrison Township in Perry County. The seam is 5 ft. thick.

INDIANA

Carlisle—The Carlisle coal mine and the Bellevue mine, near here, which have been idle two years, have been reopened.

Terre Haute—The Indiana Coal Operators Association has decided to stand back of the Queen Coal Mining Co. in its dispute at two of its mines near Jasonville over a technical construction of provisions in the contract as to certain working conditions. The Association protects its members in strikes on such occasions by providing coal to fill contracts depending on the output of the mines in trouble.

Illinois and Indiana miners will endeavor to get a uniform wage contract to succeed the two-year agreement that will expire Mar. 31. They are pleased with their individual contracts so far as they go but each state has some conditions the other one wishes and neither do the miners wish, they say, to give operators in one state any advantage in working conditions in mines over the operators of the other state, which affect the cost of production and enable one to undersell the other. William Houston, president of the Indiana United Mine Workers and vice-president Lord of the Illinois Mine Workers are drafting the contract that will be submitted for the approval first of the miners and then of the joint conference of miners and operators.

Bicknell—Aliceville is the name selected for a new coal town being promoted on coal lands owned by the Zeller & McClellan Coal Co. about three miles west of here, H. R. McClellan, Clinton, Ind., being manager of the company. The company has 6000 acres. One mine is being opened and others will be sunk.

ILLINOIS

Springfield—The United Mine Workers in Illinois are going to prevent their members from getting beat out of their wages on account of mine failures in the future if, according to rumor, the Mine Workers succeed in putting through one of the propositions that will come up as an issue in the new settlement on Apr. 1. This proposition is that every operator must put up a bond, protecting the maximum number of employees employed at each mine for twice the maximum pay roll, or something along those lines, with possibly some modifications. If they succeed in getting this proposition through, it will put a large percentage of the mines out of commission.

New Baden—A fire at the New Baden mines, twenty miles east of Belleville, recently destroyed the blacksmith, machine and storage shops and partly burnt the boiler house. The damage is estimated at $5000, and 600 men will be out of employment until repairs can be made.

Harrisburg—George F. Wilson, who absconded with $11,000 belonging to the Seventh subdistrict of District 12, United Mine Workers, has been arrested in Spokane, Wash. Officers from Herrin have gone after him. Wilson was secretary-treasurer of the district at the time of his disappearance. He deserted his wife, who is now living in East St. Louis.

SOUTH DAKOTA

Woonsocket—While boring an artesian well upon the farm of Joseph Dodd at a depth of 430 ft., a bed of soft coal, 20 ft. thick, was encountered. This was accompanied with traces of oil. As lignite coal exists in vast quantities in the northwestern part of the state, it is believed that it will also be found in paying quantities here. This discovery on the Dodd farm has caused considerable excitement throughout this section.

COLORADO

New Castle—The Coroner's jury, which has been investigating the recent explosion at the Vulcan mine rendered a verdict recently declaring that the operators did not sprinkle the mine properly, permitted the use of open lights, did not forbid smoking by the miners, and frequently fired shots while men were working in the pits. The Coryell Leasing Co. operates this mine.

Steamboat Springs—Seven members of the United Mine Workers of America charged with rioting in the miners' strike were sent out of town Jan. 3 by the Routt County Taxpayers' League. The League issued a notice that every miner in the county must find work or leave.

MONTANA

Red Lodge—Operations were recently resumed at the Brophy coal mines in the Bearcreek field following a shutdown caused by the miners going on strike because of the discharge of one of their number. The decision to return to work was reached by the local union after several fruitless conferences with the mine management in an effort to secure the reinstatement of the discharged miner.

FOREIGN NEWS

Vladivostok, Siberia—A dangerous fire recently broke out in a local mine, and was supposed to be due to incendiarism. Two hundred men were employed in the mine, and when the fire broke out 50 were underground.

Nagasaki, Japan—Recent surveys made at Iojima (an island in Nagasaki Harbor) confirmed the opinion of exports that a valuable deposit of coal exists there. Its quality is said to be the same as that of the Takashima coal and in quantity it is thought to be equal to the Nakanoshima field near Nagasaki. If this deposit proves as valuable as it is supposed to be Nagasaki will be fortunate in having an abundant supply of good coal near the entrance of its Harbor, and local business circles anticipate a revival of prosperity as the result of opening a mine.

TRADE CATALOGS

The Ingersoll Rand Co., 11 Broadway, New York. "Calix Bore Holes," 15 pages 3½x5½ in. illustrated, describing calix core drills.

Buff & Buff Mfg. Co., Jamaica Plain, Boston, Mass. "Buff," a 30-page, 4x6-in. booklet describing the construction of Buff precise transits.

The Sullivan Machinery Co., 122 South Michigan Ave., Chicago. Bulletin 66-H, "Sullivan Rock Drills." Fifty-six pages, 6x9 in.; illustrated.

The Ingersoll-Rand Co., 11 Broadway, New York City. "The Story of the Imperial." Pamphlet of 20 pages, 6x9 in., describing the manufacture of air compressors.

The Draeger Oxygen Apparatus Co., 422 First Ave., Pittsburgh, Penn., "Draeger Pulmotor." Pamphlet of 32 pages, 6x9 in., illustrating and describing the pulmotor and its uses.

The Eveland Engineering & Manufacturing Co., 2324-2328 Market St., Philadelphia, Penn., "Eveland Electric Riveter." Folder of 10 pages, 8½x11 in., describing the Eveland electric riveter.

Alberger Pump & Condenser Co., New York. Bulletin No. 18. "Alberger Spiroflo Surface Condensers." Pamphlet of 32 pages, 6x9 in., illustrating and describing Alberger condenser apparatus.

The Armstrong Cork Co., Pittsburgh, Penn. "Nonpareil Insulating Brick," 31 pages, 5x7 in., illustrating and describing an insulating brick which transmits about one-tenth as much heat as ordinary fire brick.

Coppus Engineering and Equipment Co., Worcester, Mass. "Coppus Turbo Biower." A pamphlet of 36 pages, 4x9 in. copiously illustrating and describing the details and application of the Coppus blower for increasing the draft of furnaces.

Arthur G. McKee, Contracting Engineer, Cleveland, Ohio. "Storage Bins." Pamphlet of 26 pages, illustrating and describing the Baker patent suspension type of storage bins, and the many and various uses to which these structures may be put.

The Ingersoll-Rand Co., 11 Broadway, New York, pamphlet form 8011, "Little David Riveters." Eight pages 6x9 in. illustrated; describing Little David riveting hammers with capacity for driving rivets up to from ¾ in. to 1¼ in. in diameter.

The Pneumelectric Machine Co., Syracuse, N. Y. "Pneumelectric Room Hoists," 15 pages, 6x9 in., illustrating and describing the construction and application of machines especially designed to easily and quickly handle cars over local dips, grades, etc., and make easier and more effective the work of both men and mules.

PERSONALS

George Wales, civil and mining engineer, has been appointed city engineer of Central City, Ky.

John M. Roan, member of the recent Ohio State Mining Commission, has been appointed to take charge of the safety and accident prevention bureau of the mining department.

John Sanderson, of Red Lodge, Carbon County, Mont., succeeded J. B. McDermott as state coal mine inspector of Montana on Jan. 1. Mr. McDermott held this position long and creditably.

"Mother" Jones, prominent labor leader, was recently deported from Trinidad, Colo. She was met at the train and ordered to get back on board and continue traveling until out of the strike district.

E. J. Pietzcker formerly Southwestern Sales Manager for the Standard Underground Cable Co., has been made Western and Southwestern Manager for the same firm, in charge of the offices in both Chicago and St. Louis.

Thomas M. Jenkins, of St. Louis, has been appointed general manager of the St. Louis & O'Fallon Coal Co. The mines of the company are located in the vicinity of O'Fallon, Ill., and last year produced 7,000,000 tons of coal.

Neal Robertson, of Charleston, W. Va., recently appointed receiver of the La Folette Coal, Iron & Ry. Co., of La Folette, Tenn., after spending a week at the operation left on Jan. 3 for New York, on business connected with the receivership.

Clarence Hall having acted in the capacity of expert in charge of the explosive section of the U. S. Bureau of Mines for seven years, has tendered his resignation in order to establish an industrial laboratory in the city of Pittsburgh. Analyses and tests of explosives will be made a specialty.

William Haggerty, recently underground superintendent of the Red Lodge coal mines of the Northwestern Improvement Co., has been raised to the position of superintendent of the whole works. C. C. Anderson, who held this position prior to Mr. Haggerty's elevation, is now general manager of the company and all the coal properties of the Northern Pacific System.

OBITUARY

James Lackey, a prominent member of the Philadelphia Coal Exchange, died in that city recently after a slight illness. He began business in Philadelphia about 35 years ago.

John Skeath, mining expert, recently died at the state hospital at Mahanoy City, following a stroke of paralysis, at the age of 70 years. Mr. Skeath began life as a slate picker, became chute boss, foreman, superintendent and finally general manager for the Reading Coal Co. in this district.

CONSTRUCTION NEWS

Cannonsburg, Penn.—The Pittsburgh Coal Co. is digging a shaft on what was formerly the Hopper farm about half a mile from Hill's station.

Brownsville, Penn.—The Denbeau Coke Co. plans to erect 64 ovens next spring, which will make its plant one of 300 ovens of the rectangular type. It is also planned to erect a $50,000 washer.

Cumberland, Md.—Work will begin shortly on the new nine-mile railroad branch of the Federal Clay, Coal and Lumber Co. from Cooksville Mills, Penn., to Confluence tapping a rich coal and timber country.

Roscoe, Penn.—Work has begun upon the building of the new tipple for the Eclipse mine above Wood Run station. This structure is to cost about $70,000. Work of erection is in charge of the Bravo Construction Co.

Connellsville, Penn.—The Snowden Coke Co., of Pittsburgh, has recently bought the plant of the Mt. Hope Coke Co. and about 1050 acres of coal adjoining from other owners. It is planned to increase the present plant from 150 rectangular ovens to 400.

Kingwood, W. Va.—The North American Coal Co., of W. Va., has closed an agreement with James A. Comley, of Morgantown, for the development of a tract of 100 acres of coal on the Monongahela River and along the Buckhannon & Northern R.R.

Clarksburg, W. Va.—The Clarksburg Northern R.R. has been completed to the corporate limit of Middlebourne, and but one bridge prevents entrance to the town. The last rail before crossing the creek will soon be laid, and the completion of the road will be made an important event by the people of Tyler and Wetzel Counties.

Huntington, W. Va.—In order to furnish power to about 12 coal operations that are located upon its holdings, the firm of Montgomery Clothier & Tyler, of Philadelphia, has installed a plant at Sharples, W. Va., on Coal River, at a cost of about $75,000. This plant will furnish power to operations for miles around, having a capacity of 1000 kw.

Youngstown, Ohio—Work is progressing rapidly on the byproduct coke plant being built by the Republic Iron & Steel Co. It will contain 68 byproduct ovens of the Koppers type and will have a daily capacity of 800 to 1000 tons. It is expected that this plant will make enough coke to supply the company's blast furnaces in the Youngstown district.

Connellsville, Penn.—The Pennsylvania R.R. has completed the extension of the Monongahela & Southern from Rice's Landing to the Crucible Coal Works, and passenger trains are being operated daily over the additional trackage. It is understood that eventually this road will be extended up the Monongahela River to Queensboro, where it will connect with the Monongahela R.R.

Morgantown, W. Va.—About 25 men have been put to work on the siding for the mine to be opened on the Comley property, about half a mile above Maidsville, by the North Ameri-

can Coal Co. While the siding is being put in by one gang, another force is at work opening up the mine, which is to be operated as a drift. Work on the tipple will be started as soon as the siding is in.

Woodward, Ala.—Between $700,000 and $1,000,000 will be expended by the Woodward Iron Co. and allied interests in the construction of new plants during the present year. This is the beginning of a series of additions to be made at Woodward. It is announced that 30 by-product coke ovens will be started within the next 30 days. In addition to this a creosoting plant will be erected by the American Creosoting Co., which will be one of the most modern in the South.

NEW INCORPORATIONS

Lynchburg, Va.—The Black Wolf Coal & Coke Co. has increased its capital stock from $150,000 to $225,000.

Sheboygan, Wis.—The C. Reiss Coal Co. of Sheboygan has filed an ammendment increasing its capital from $800,000 to $2,000,000.

Shinnston, W. Va.—The Bridgeport Gas Coal Co. has been incorporated here with a capital stock of $50,000 to develop coal mines.

Frankfort, Ky.—The Bank Coal Co., of Williamsburg, recently filed amended articles of incorporation, increasing the capital stock from $6000 to $8100.

Sullivan, Ind.—The Vance Coal Co. has been organized with a capital stock of $10,000. The directors are O. P. Smith, B. W. Lovett, W. H. Vance and others.

Cleveland, Ohio—Notice has been filed by the Kea Coal Co., of Cleveland, of an increase in its capital stock from $10,000 to $150,000 and of a change of name to the Indian Hill Coal Co.

Chicago, Ill.—A certificate of increase in capital stock of the Southern Illinois Coal & Coke Co. with headquarters in Chicago, was recently filed at Dover, Del. The increase is from $1,000,000 to $1,200,000.

Wheeling, W. Va.—The James H. Emblem Co. has been incorporated with a capital stock of $100,000 to manufacture coke and sell coal and gas. The incorporators are James H., Robert, Albert, George, Sarah and Rosella Emblem.

Charlestown, W. Va.—The Gassaway Coal Oil and Gas Co. of Gassaway has been organized for the purpose of operating oil, gas and coal. The capital stock is $25,000 of which amount $500 has been subscribed and $50 paid. The incorporators are: Grace Jacob, C. J., L. G. and A. L. Schearer.

Great Falls, Mont.—The National Coal Co. has been recently incorporated to carry on a general coal and fuel business. The capitalization is $100,000, and it is declared by the organizers that the new concern is one of the largest fuel companies in the Northwest.

Charlestown, W. Va.—The Extrapoca Coal Co. has been organized at Bramwell, Mercer Co. for the purpose of operating coal mines in McDowell Co. The capital stock is $10,000 of which amount $500 has been subscribed and $50 paid. The incorporators are: J. F. Biggs, H. S. Brown, B. W. Freeman, J. E. Jones, and Hattie Brown.

Logan, W. Va.—The Reece Coal Co. has been organized with a capital stock of $25,000 for the purpose of mining coal and manufacturing coke. The incorporators are J. C. Alderson, F. B. Robertson, R. L. Shrewsbury, of Logan, W. Va., L. E. Browning, Reece Browning, of Chancey, W. Va., and T. O. Deaumer, of Huntington, W. Va.

INDUSTRIAL NEWS

Pittsburgh, Penn.—Pittsburgh officials of the Pennsylvania R.R. predict an increase in the coal traffic in January which will continue until after Mar. 1.

Harrisburg, Ill.—The Guaranty Trust Co., of Chicago, has sold to the Chicago Harrisburg Coal Co. about 20,000 acres of coal land in the western section of Saline County.

Berlin, Germany—A mining engineer at Bochum is said to have invented a successful wireless apparatus for signalling the imminence of perilous conditions inside a coal mine to the station at the pit mouth.

Morgantown, W. Va.—The first shipment of coal over the Buckhannon & Northern R.R. was recently made from the newly opened mine of the Sterling Co., on the west side of the Monongahela river opposite Point Marion.

Washington, D. C.—J. G. Wright, commissioner to the five civilized tribes of Oklahoma has been authorized to make new leases for the surface of the segregated coal and asphalt lands of the Choctaw and Chickasaw indians for another year.

Punxsutawney, Penn.—Deeds for 17 tracts aggregating 1700 acres of coal land in East and West Wheatfield townships have been recorded by attorney Frank P. Barnhart for the Operators' Coal Co.

Brownwood, Texas—What is believed to be a large field of lignite has been discovered in the eastern portion of Brown Co. and more than a 1000 acres have been leased to Wright Stewart and G. F. Wilson.

Berlin, Penn.—About 1000 acres of coal land belonging to the Johnson estate adjoining the holdings of the Brothers Valley Coal Co. have been recently sold to the Brothers Valley interests for what is said to be $100 per acre.

Marion, Ill.—The Black Diamond R.R. recently sold at auction and was bid in by E. M. Stotlar for $28,200. A coal mine was included with the road which is graded 12 miles east of Marion and is in operation as far as Pittsburg which is six miles distant.

Huntington, W. Va.—Fifteen of the 70 steel hopper-bottom cars ordered from a Butler, Penn., firm by the Chesapeake & Ohio R.R., have arrived and were taken to the coal fields. It is said that these cars will be used principally for the shipment of coal to tidewater.

West Newton, Penn.—Jacob F. Paterson, of Waynesburg has purchased from David M. Comstock and J. D. Loughman, of Morris Township their interests amounting to 50 acres in what is known as the Frederick Loughman tract of land near Deer Lick in Greene Co. for $260 per acre.

Franklin, Penn.—The Pennsylvania Southern, Pennsylvania Northern & Pittsburgh, and Clarion and Northern railroads have been merged into the Lake Erie, Franklin & Clarion R.R. The roads in the merger are in Venango and Clarion counties and traverse important coal lands.

Eaton Rapids, Mich.—Coal in paying quantities has been unearthed by the digging of a well on a 600-acre tract of land between this city and Albion. A mine has been in operation upon this tract for some time, but the drilling of this well revealed the presence of another deposit of coal which is said to be 4 ft. in thickness.

Washington, D. C.—The beehive type of coke oven which does not admit of the recovery of by-products from the distillation, according to the Department of Agriculture is responsible for an annual waste in the United States of $22,000,000. About $4,000,000 worth of ammonia is obtained annually as a by-product of coke making, while more than five times that amount is allowed to go to waste.

Washington, Penn.—As the result of a coal deal recently closed it is expected that Owen Murphy a coal operator of Latrobe will shortly open a coal mine in Coon Island in southwestern Washington Co. It is alleged that Mr. Murphy has come into possesion of approximately 400 acres of coal and has options on two pieces of surface just outside the town, on one of which the shaft is to be sunk.

Seattle, Wash.—Eight hundred and forty miners employed in the Black Diamond mines of the Pacific Coast Coal Co. refused to work recently alleging that they were not properly safeguarded in the mines. The District Executive Board of the United Mine Workers of America upheld the action of the miners. If the allegations of the men are found to be correct, they will remain out until proper safeguards are installed.

Chicago, Ill.—A newly patented electrical primary battery, said to have been invented by a man in Washington, D. C., is being heralded in Chicago and other Illinois cities as "coming within 5 per cent. of perpetual motion." The salesmen openly affirm that when the invention is spread throughout the country, "the coal mines may as well shut up or down," for heat, light and power will be dispensed to stockholders at one-tenth the present cost.

Philadelphia, Penn.—The year 1913 proved one of the most prosperous in the general business of the port of Philadelphia, although the figures recently issued by collector Berry show a decline which, obtained on a limited number of products only. Bituminous coal one of the principal exports showed a substantial increase in volume and valuation over the year of 1912. During this time the exports amounted to $2,378,299 as compared with $2,590,954 for 1913.

Coal Trade Reviews

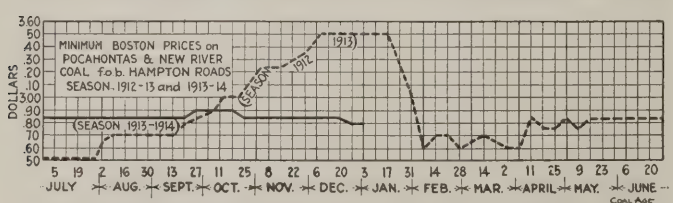
General Review

Hard coal still dull; colder weather and labor difficulty in New York Harbor have a stimulating local effect. Congestion of bituminous general at most of the distributing centers. Prices soft under adverse conditions, but showing a stubborn resistance on the decline.

Even under the combined influence of severe weather conditions, and an almost complete tie-up of water transportation in New York Harbor, the anthracite market has still failed to show the customary winter buoyancy. Tidewater demand is light at the best, and all companies are heavily stocked. The restricted production over the holidays has not relieved the situation, and unless there is a long continued spell of moderately severe weather, it may ultimately prove necessary to effect a further curtailment in the output.

Biuminous consumers are still carrying full stocks, and the congestion is noticeable everywhere. It is more difficult to negotiate business now than during last summer, but sellers are not, as a rule, attempting to force the market, appreciating the futility of adopting any such policy. The strike in New York Harbor has interfered with water deliveries and caused a congestion at some of the loading ports, but the situation has not developed to serious proportions as yet, and the rail movement continues in good volume. There has been an excess accumulation at the Hampton Road piers, and as a consequence, there is a superabundance of the Southern fuels in the New England markets, which has caused a sharp break in the Pennsylvania grades.

The long continued mild weather in Ohio, together with the slowing down in manufacturing over the halidays, resulted in a further slump in the market there; stocks are heavy, and consumers are loath to place further orders until these can be moved. Business at Hampton Roads is only fair, few spot sales being negotiated; the bunker prices for 1914 were announced Jan. 1 on the same basis as last year. Colder weather in the South has created a more active situation there, and stocks are somewhat reduced. Steam coal is quiet, but with an excellent undertone; car situation much improved. A deficiency in the supplies of fuel oil at New Orleans has caused an unusual activity in the coal markets.



A more optimistic tone pervades the Middle Western market as a result of the colder weather. There is an increased demand, and while prices have not advanced as yet, there is a strong inclination toward higher levels. The manufacturing demand is getting under way again after the holiday cessation, and there is greater activity in retail circles, though this has not been felt in the wholesale end as yet.

EASTERN MARKET

BOSTON, MASS.

Bituminous market shows no material change. Still a large accumulation of New River and Pocahontas at Hampton Roads.. Pennsylvania are largely affected by the abundance of Southern coals. Anthracite has yet to show the brisker movement expected on account of the present cold snap.

Bituminous—The market continues generally inactive. There is still an accumulation of coal at Hampton Roads in excess of chartered tonnage and though as yet the circular f.o.b. price of $2.85 for New River and Pocahontas has been

fairly well maintained, several instances of shading have been reported. The New England market is so well stocked that it will probably be several weeks before this present cold weather has any effect. Pennsylvanias for tidewater shipments have become considerably weaker owing to the superabundance of Southern coals. Georges Creek remains in good supply with a firm price. Contract demand in all quarters is slight.

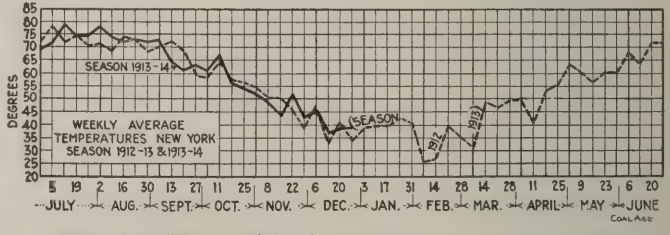
The market continues quotable as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$1.00@1.55	$1.25@1.60	$1.67@1.77	
Philadelphia*	2.25@2.75	2.50@2.85	2.92@3.02	
New York*	2.55@3.05	2.80@3.15	3.22@3.32	
Baltimore*			2.80@2.90	
Hampton Roads*				$2.80@2.90
Boston†				3.72@3.82
Providence†				3.72@3.87

*F.o.b. †On cars.

Anthracite—This market remains listless, its only feature being the scarcity of stove coal. It is hoped that the present cold weather will soon produce a brisker demand but as yet the effect has been negligible. Freight rates are still 70@75c., Hampton Roads to Boston, but a strike of the captains in New York Harbor is bound to have an early effect.

NEW YORK



Strike of the barge captains in New York Harbor the feature of the local market. Conditions easy as yet due to large stocks of all kinds. Colder weather having a stimulating effect.

Bituminous—The strike of the boat captains has held up deliveries of coal to a considerable extent, and to prevent a congestion at South Amboy Piers, the Pennsylvania Railroad placed an embargo, the latter part of last week, on shipments to that point. Should the strike continue for any length of time, the other roads will undoubtedly find it necessary to take similar action. Ordinarily, such a situation at New York might force the coal into other channels, but mining operations have been somewhat curtailed this week by the severe weather conditions in the several regions. With the exception of those plants which have little or no storage capacity, the interruption to deliveries in New York Harbor is not likely to be serious.

Coal continues to move freely to consumers reached via all-rail, and a prolonged suspension of deliveries by rail and water would undoubtedly compel some water consignees to take their coal in via the rail routes.

The market continues quotable as follows:

West Virginia steam, $2.60@2.75; fair grades of Pennsylvania, $2.70@2.80 good grades of Pennsylvania, $2.80@2.90; best Miller Pennsylvania, $3.10@3.20; George's Creek, $3.15@3.25.

Anthracite—Even with the suspension of mining due to the holiday season, there has been little noticeable improvement in the demand for prepared sizes. Most of the cheap egg coal which has been offering in the market for the past month or so has practically dissappeared; this size seems to be moving along fairly well now with the stove and chestnut at, or about, circular prices. During the past week, however, pea coal was quite short in the local market as well as the better grades of buckwheat, while the poorer grades are still offering at a discount.

The strike of the boat captains, Jan. 2, has not up to this writing seriously handicapped the movement of coal since the stocks in the hands of the retailers were good. The shipments to tidewater have been light for the past week and the failure to move boats on account of the strike has not seriously effected the docks. It is not generally thought that the strike will be of long duration. The captains, of course, live on the boats and in striking they deprive themselves of a home. This together with the fact that they have in most cases very little money to carry themselves along during this inclement weather should lead to a speedy settlement.

We quote the New York market on the following basis:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.00	.....	$5.05	.....
Egg	5.25	$5.15@5.25	5.30	$5.10@5.20
Stove	5.25	5.25	5.30	5.20
Chestnut	5.50	5.50	5.55	5.35@5.45
Pea	3.50	3.50	3.50	3.35@3.45
Buckwheat	2.75	3.50	2.70@3.45	2.25@2.70
Rice	2.25	2.25	1.95@2.20	1.75@2.20
Barley	1.75	1.70@1.75	1.70	1.40@1.70

PHILADELPHIA

General restriction of production continues and market remains apathetic. New year holds little promise for operator and retailer. Demand exceedingly light.

The year 1913 closed with the lightest demand for hard coal in months, and little hope is entertained for relief. The new year was eagerly looked forward to by operators and dealers, but at the present time it hardly seems probable that the market will harden until seasonable weather arrives.

Business has sagged and everyone is anxiously waiting for it to recover. A general restriction of production continues, and it has been a long time since the local market was so dead. Two years ago the trade had a similar experience, and it was late in February before it started to show its real form. Reports from the mines state that individual operators are mining full time, but that they are compelled to make concessions in prices on every size in order to move their product. It is evident that the anthracite supplies are fully adequate, but the demand cannot be found as yet.

The bituminous market remains unsatisfactory. Prices for good coals continue to show resistance against any further decline, and persistently hold around the same level. Some poorer grades have eased off since the holidays. The production is being sharply curtailed partly by voluntary action on the part of the operators and partly as a result of the holidays.

BALTIMORE, MD.

The year is started with more winter-like weather, but with the trade still rather flat. Plenty of fuel on hand despite the holiday period. Anthracite conditions brisker. Coal exports break record.

Wintry weather conditions have marked the first week of the New Year, and while a continuance is likely to result in a stiffening of the coal trade as a whole, business just now is flat. The bituminous call remains remarkably poor for the season, most consumers reporting that they are loaded up to such an extent that they can take no more coal for a time. In West Virginia the steam coals of medium grade are still commanding around 90c., while gas coals range from 65c. for slack to around 85c. for three-quarter. The Pennsylvania coals show no marked change, first grades still calling for about $1.25 and other classes selling down to 90 cents.

There is plenty of fuel on hand despite the holiday period. Nearly all mining interests were making reasonable offerings to the trade to keep fuel moving and to prevent congestion at the loading points.

Anthracite conditions showed an improvement. Much interest is being taken in the trade in a move under way to consolidate about twenty of the largest retail concerns here, much on the plan pursued some time ago in both Philadelphia and New York.

The coal exports from Baltimore for 1913 broke the record. In 1912 the total exports was 628,522 tons, while the past year saw a foreign movement from this port of 870,751 tons.

CENTRAL STATES

PITTSBURGH, PENN.

Production greatly curtailed in past fortnight. Demand light and weather unseasonable. Prices being cut somewhat. Connellsville coke market less active. Rumors of dissensions among leading operators.

Bituminous—There has been only about one week of operation in the fortnight, on account of the holidays, and as some mines were closed altogether before the holidays, production has been light. Consumption has also been small and prospects are not good in this respect, manufacturing demand being poor while the weather on the whole is unseasonably warm. Not much prompt coal is moving and there has been little contracting for the three months, while annual contracts are few as they would extend over the wage settlement and on account of the uncertainties such contracts are avoided equally by buyers and sellers. Relatively little prompt coal is moving, and there is some cutting. Regular prices, which are usually quoted, remain as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—Contracting for furnace coke for the new year has not been pursued with any avidity in the past few days, or since contracts for 125,000 to 150,000 tons a month were made about a week ago, at from $1.85 to $1.95. It is claimed that the regular asking price of $2 has been paid in two or three instances, but chiefly for January tonnages only. Rumors are numerous that there is trouble among the companies which have been selling, or perhaps more accurately speaking holding their product for sale, through the Producers Coke Co. One rumor has it that several companies are withdrawing while another is to the effect that the company will reduce its asking price. This might avail little, seeing that there is not much more coke to be covered.

Prompt furnace coke is quiet, but unquestionably higher. Corrigan, McKinney & Co. have blown out two of their five stacks and have bought 8000 tons of prompt coke at $1.75, intending to run their three furnaces a short time longer. We quote: Prompt furnace, $1.90@1.95; contract furnace, $1.85@2; prompt foundry, $2.40@2.65; contract foundry, $2.40@2.65, per ton at ovens.

The "Courier" reports productions in the Connellsville and lower Connellsville region in the week ending Dec. 27 at 236,085 tons, a decrease of 48,851 tons, and shipments at 233,581 tons, a decrease of 44,774 tons.

BUFFALO, N. Y.

Still a quiet market. Dealers do not look for much recovery this month. Coal on track and business in retail centers heavy. Preparations for the spring suspension.

Bituminous—There is still much difficulty in getting the surplus supply out of the way. Jobbers are holding back the production as much as possible, and the result is a lot of cars standing on track on demurrage. It is the good salesman and careful manager who is making money out of the business now.

Coal will not sell half as readily now as it would last July. The retailer and the consumer are so loaded up with stock, that neither of them is able to take any more while actual consumption has gone off somewhat and the congestion is noticeable everywhere. Even if the consumption increases it is estimated that a month will be needed to make any headway against the oversupply and it may even take a big spring suspension of the mines to wipe out the surplus. The spring suspension is fully expected to take place, though it may not be long. The miners are well supplied with funds so that it may turn on how soon the operators wish to get back to business or on the effort of some district attempting to get started ahead of another. Such has been the situation in former years. Coal sellers are not trying to push the market very hard appreciating the futility of such an action. The consumer is not afraid of running out of stock and treats the talk of a spring strike with contempt. Bituminous prices are unsteady and do not rule above $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.25 for mine-run and $2.15 for slack, with slack doing a little better than sizes. Allegheny Valley coal follows Pittsburgh closely, but on account of the lower freight rate in this market it sells for about 25c. less.

Coke—The demand for coke is still light and the small promise last week of a firmer market soon does not appear to have been realized. Dealers do not agree as to the outlook; some believe a generally better state of trade will compel a revival of the iron trade. Coke quotations remain weak at $4.60 for best Connellsville foundry.

Anthracite—The late winter snow has not brought about any larger demand as yet. In fact many of the mines, including the independents, are running on only part time and with coal on demurrage at various points, the anthracite trade is not without its difficulties. There begins to be fear that the big supply shipped West by Lake will not all be required this winter.

One company has a large amount of coal on hand here and is loading into lake vessels. The amount put afloat so far is more than 40,000 tons, with prospects of a continuation. As a rule the other companies do not appear to be anxious to tie up their coal in that way and there are certainly two sides to the question. A long spring suspension of mining tied up the anthracite trade West very badly two years ago, which a good amount afloat here would have prevented.

TORONTO, CAN.

Colder weather created some activity in anthracite. A projected municipal coal yard.

Trade showed considerable improvement during the past

week owing to the setting in of cold weather; anthracite for domestic purposes is moving freely, many having allowed their supplies to become low so long as mild weather lasted. An active business for January is anticipated. Quotations remain unchanged.

The City Council of Toronto, in pursuance of a project for the establishment of municipal coal yards, which has been advocated from time to time, has applied to the Provincial Legislature for an amendment to the civic charter to enable them to engage in the coal business. The dealers do not consider that there is much likelihood of its adoption.

COLUMBUS, OHIO

Combination of adverse factors in the local trade. Continuation of mild weather and the closing down of many manufacturing plants caused very quiet trade. Movement small in every line and prices again slumped in spite of the efforts of the larger operators and jobbers to maintain the circular.

Production was at a low point during last week. Because of the holiday, which always means a cessation of work and little demand for steam and domestic grades, the output in the various mining districts was small. In the Hocking Valley the production was about 35 per cent. of the average and the same is true of eastern Ohio and Pomeroy Bend. In the domestic fields of Jackson, Massillon and Cambridge the output was even less.

Domestic trade is dead in every way. Dealers stocks are large and they are loath to place orders until they are able to move what they have. The larger householders have laid in their supply for the winter and the domestic trade is now largely a weather proposition. Orders placed for delivery in January have either been canceled or deferred. Collections are bad as a result of the inability of dealers to move their stocks.

There is more doing in steam lines but even this department is feeling the effects of the holiday vacation and the business depression. Many plants which have shut down temporarily have not yet started while others are on part time. Their fuel consumption is not at all large. The movement on the part of some steam users to stock up against a possible suspension after Apr. 1, has not caused much effect on the trade. Contracts are being renewed on the same basis that prevailed during the past year. There is practically nothing doing in retail circles. Dealers are not busy and many of their wagons have not been out for several days.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.75 @ 1.70	.....	$1.90 @ 1.80	$1.70 @ 1.60
3-4 inch	1.50 @ 1.45	$1.20 @ 1.15	1.60 @ 1.40	1.50 @ 1.45
Nut	1.30 @ 1.25	.....	1.50 @ 1.40	1.30 @ 1.25
Mine-run	1.30 @ 1.25	1.10 @ 1.05	1.30 @ 1.25	1.30 @ 1.25
Nut, pea and slack	0.80 @ 0.75	.....	0.90 @ 0.85	0.80 @ 0.75
Coarse slack	0.70 @ 0.65	0.90 @ 0.85	0.80 @ 0.75	0.70 @ 0.65

DETROIT, MICH.

The long period of mild weather has caused a general heaviness in the market. Railroad yards congested with coal.

Bituminous—The unusually mild weather has caused a falling off in the local trade and it is now entirely a weather market. The railroad yards are crowded with coal, and with shipments still coming in there is considerable forced selling to avoid demurrage. The domestic business is suffering the worst as would be expected. Stocks generally appear to be large, and with consumption light there is little or no excuse for any business.

Steam trade is adversely affected by the slowing down in business. Cancellations and hold-over orders are reported on all sides. Railroads are giving an almost perfect service. Operators have exhausted practically every effort to maintain prices which are now weak. Domestic lump is quoted at $1.35, the regular circular being $1.75@1.85. While three-quarter lump is quoted at $1.60 the mines, it can be obtained apparently in any quantities at $1.10 in Detroit.

The market is quotable on the following basis:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump	$1.45	....	$1.50	....	....	$2.40	$2.25
Egg	1.45	....	1.50	....	....	2.40	2.25
Nut	1.20	....	1.10	....	....	....	....
Steam lump	1.20	....	....	....	....	....	....
¾-in. lump	1.10	$1.10	1.10	$1.10	$1.10	....	....
Mine-run	1.00	1.00	1.00	1.00	1.00	1.25	....
Slack	0.75	0.80	0.60	0.65	0.65	....	....

Anthracite—Hard coal is in light demand, business negotiated being about the same as occurs in a normal summer market. The circular is being freely shaded as much as 50c. in some instances, and there is considerable coal unsold.

Coke—Coke is in practically no demand at all. Connersville is quoted at $1.75, with Semet Solvay at $2.85 and gas house $2.65 f.o.b. ovens. Local ovens have suspended operations indefinitely.

HAMPTON ROADS, VA.

Dumpings for the week fair. About normal accumulation at tidewater, total shipments for December over one million tons.

The movement from Hampton Roads during the past week has been only fair. The demand has not been so heavy owing no doubt to the holiday season and such shipments as have moved were mostly on contract business. Very little spot coal was sold during the week, and those made covered only small parcels. Bunker prices for 1914 went into effect on the first, the contract figures being the same as for 1913. In addition to coastwise shipments, principally to New England, coal has moved during the week to Coronel, Vera Cruz, Naples, St. Louis and Cristobal.

During the month of December the Norfolk & Western dumped over their piers at Lamberts Point 514,020 tons, The Virginian Ry. at Sewalls Point 267,632 tons and the Chesapeake & Ohio Ry. at Newport News, 274,734 tons. These figures show a considerable falling off in the Virginian Ry. tonnage as compared with their previous month's dumpings. The total dumpings over the three Hampton Roads terminals for 1913 amounted to 11,993,658 tons. This is the greatest amount of coal ever shipped in any one year from Virginian Tidewater, the dumpings for 1912 being a close second with 11,437,987 tons.

LOUISVILLE, KY.

Advent of winter weather stimulated buying. Curtailment over holidays created a mild shortage. Prices more buoyant.

The most disagreeable weather of the year resulted in an immediate improvement of the coal market in this section, the increased demand with the retailers being reflected at once in orders upon the wholesalers and operators. This improved demand, coupled with the usual holiday lay-off resulted in something like a shortage. Most of the available fuel on tracks was eagerly snapped up in the early part of the week, at increased prices, as compared with those prevailing a short time ago. It is apparent that stocks laid in early in the season are about exhausted and with a heavy consumption an equally steady demand is certain.

The steam market is in equally good shape; as yet the short supply available last week has not been considerably improved, owing largely to the same conditions as prevail in the domestic market. In consequence almost anything in the shape of screenings has sold readily, the lower grades being freely placed where usually only first-class Eastern Kentucky coals have been acceptable. This will probably ease up considerably with the increased production of the prepared grades, but there should be a good demand, sufficient to take care of a large and steady supply, for the remainder of the winter. The car supply has been adequate for the comparatively slight output at the mines during the holiday season; whether it will continue so when full operations are resumed is a question with the mine owners.

Prices for delivery this month are quoted at $2.15 for the better grades of Eastern Kentucky block, $1.85 for block and lump, and $1.55 for round, with nut and slack in active demand at 85 to 95c. Western Kentucky is in fairly good call at $1.25 for block, with some sales a little higher, and 65 to 75c. a ton for nut and slack.

SOUTHERN AND MIDDLE-WESTERN

BIRMINGHAM, ALA.

Cold weather for the last few days has had a stimulating effect on lump coal. Steam grades quiet. Blacksmith coal in satisfactory condition. Furnace and foundry coke dull. Pig iron more active.

For the past few days freezing weather has had rather a stimulating effect on lump coal, and while the operators have not yet reaped any benefit, the accumulated stocks in dealers hands and in railroad yards have been greatly depleted. A week more of cold weather will bring about a decided change for the better in lump coal; the present market is still quiet, but with a more cheerful outlook.

Steam coal shows little change over last week. The output is really in excess of the demand, as all of the mines have resumed operations since the Christmas holidays. The operators are feeling more optimistic, however, over the prospects for a good business. Blacksmith coal is normal, the

tonnage handled being about the average for this season.

Both furnace and foundry coke are still quiet, with no immediate prospects of improvement. Pig iron was considerably more active this week, a good tonnage being booked by the Birmingham manufacturers. Buying for the first quarter and half of 1914 has started, and the furnaces are expecting a most favorable year. Prices are firm at $11 f.o.b. Birmingham for 2 Foundry. The car situation has improved within the last week or ten days, due partly to the mines being closed down over the holidays.

NEW ORLEANS

Parcel shipments to Mexico and Central American points heavy. Honduras principal buyer. East Texas and west Louisiana taking more than usual. Alabama coal reaches New Orleans by water route.

Heavy parcel shipments of coal to Mexico and Central American points was the only feature in the coal market here last week. Honduras was the largest buyer. Numerous shipments were made to Costa Rica and Guatemala. Colder weather made the city demand heavy although total sales in the city are fully 30% under normal, thus far this winter.

Shipment of coal to points along the Southern Pacific Railroad and Louisiana and east Texas are much heavier than usual at this time of the year. This is due entirely to the fact that the strike six weeks ago has cut off fuel oil shipments. The dealers are buying now in a hand-to-mouth manner, so as to be able to supply their trade, but without stocking up for more than their requirements.

Two barge loads of coal have arrived from Alabama fields. These trips have not been satisfactory owing to the low stage of the Warrior and Tombigbee rivers. It is probable that no future attempts to bring coal on barges will be made until the government locks in the upper rivers have been completed. This means that the prevailing prices will continue in effect for at least a year. Introduction of water transported coal threatens to lop 50c. off the prevailing quotations.

INDIANAPOLIS

No change in trade conditions or prices. Some operators, tired of waiting for winter weather, are reported making concessions. Signs of improvement in factory demand.

January is usually a good month for the coal business but so far it gives no evidence of living up to its past reputation. However there is a light mantle of snow over most of the state and this has been a stimulant. As stocks are ample, the increased demand has not yet reached operators and mines continue to work on short schedule where they are not entirely closed down. This condition is not likely to last as retailers will soon be in the market again, unless the winter breaks the record for mildness. The less optimistic producers are reported to be shading prices, to catch such emergency orders as are available and to induce those who have made holes in their stocks to fill them up again at a bargain.

While it has been comparatively easy to get $1.90 to $2 for domestic lump, orders are now being booked mostly below these figures, perhaps around $1.80, while some sales are even reported 20 to 30c. below this. Operators point out, however, that there is considerable difference in the quality, and that the best domestic lump is still worth $1.90 to $2; and further that it is being sold at that figure. Mine-run has a range of $1.10 to $1.20 and screenings 60 to 75c. The factory demand shows signs of improvement as there is considerable preparation for getting operations back to normal again. Car shortage has been eliminated by the general slacking of operations.

Retail prices in this city still stand at the only advance made since spring, which went in effect Sept. 20. Fortunately for the yards, this raise was almost to the usual high mark for winter and was caused by the fear of not being able to get a sufficient supply of coal on account of the car shortage in September and October. Anthracite sells at $7.75@8.50, according to grade; Pocahontas at $5@6.50; Eastern bituminous, $4.75@5.50; Indiana lump, $3.50; Brazil block, $4.25 and coke, $6.50.

ST. LOUIS, MO.

Colder weather has appeared and there is a generally more optimistic tone. Steam coal in good demand.

Colder weather has brought about somewhat better conditions, and the trade seems to have an optimistic view of future conditions. While the weather has brought some demand, it has not been sufficient to make much change in prices, although there is an inclination that way.

Steam coal is in good demand, and the price of screenings is getting back to where it was last spring and summer. Carterville and Franklin County are hovering around 80c. at the mines, while Standard screenings are in good demand at 55@60c. The smaller sizes of washed coal are hard to get at any price, while the domestic grades are not moving. The better coals from the high grade field are still holding up at good prices, but there is always some tonnage of inferior coal that is under demurrage and taking whatever the market will bring. There is some demand for anthracite and a little call for smokeless, but the coke market is heavy.

The prevailing market is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump	.....	.....	.....	$0.90@1.00
3-in. lump	.....	.....	$1.40	.....

No. 4 washed nut	1.05	.....	.....	.....
No. 5 washed nut	0.50	.....	.....	.....

KANSAS CITY, MO.

Outlook much improved with the colder weather. Stocks being diminished and orders are more plentiful. Production increased.

The coldest weather of the season has prevailed in Kansas and Missouri during the past two weeks, and coal operators are more optimistic than for some time past. While dealers are not yet ordering heavily, their stocks are being diminished rapidly and the prospects are considered excellent. Many business houses which ordered as lightly as possible before their annual inventories, are now anticipating their requirements thirty or forty days.

The market, which has been weak for some time past, is showing more strength, and operators are more inclined to stand by their quotations. Most of the mines in Kansas and Missouri have taken a brace, as far as output is concerned, and are now working from one-half to two-thirds time. If the weather continues favorable, many of the mines will be worked to capacity during the next week.

PRODUCTION AND TRANSPORTATION STATISTICS

NORFOLK & WESTERN

The following is a statement of the tonnage shipped over this road during November, 1913, and the first eleven months, as compared with corresponding periods of 1912 in short tons:

	November		Eleven Months	
Coal	1912	1913	1912	1913
Tidewater, foreign	83,877	50,154	1,259,228	1,392,064

Financial Department

Virginia Iron, Coal & Coke Co.

President John B. Newton reports in part, for the year ending June 30, 1913, as follows:

Results—Although the year 1912-13 started out full of encouragement, the demand for iron had by Dec. 31 fallen off, prices dropping until in May 1913 the low level of 1911 was reached. The market remained through June and July; today, while it is by no means strong, there is a better feeling and indications point to more demand and better prices. During the few months of active market we booked sales of 230,000 tons of iron, at fairly remunerative prices.

The blast furnaces at Radford and Roanoke were operated continuously and the Pulaski furnace for six months of the year, producing a total of 130,435 tons of coke iron, while the charcoal furnace at Foster Falls turned out 2912 tons of cold-blast charcoal iron. On June 30, 1912, we had 163,826 tons of pig iron on hand; on June 30, 1913, only 60,000 tons, we having shipped from current make and out of stock a total of 237,608.

Our coal business has continued to grow, both in volume and profit. The mines produced 1,840,213 tons, at a profit of $353,655, as against 1,563,284 tons at a profit of $309,419 the preceding year. At Toms Creek (your largest operation) the most modern all-steel tipple obtainable should be completed by Oct. 1 of this year, substantially increasing production.

Exchange of Coal Lands—We have concluded negotiations with the Clinchfield Coal Corporation for the exchange of certain interlocking coal lands in Wise County, Va., making it practicable to mine the maximum amount of coal with the least possible waste.

Bonds—We have retired by purchase $21,000 additional of our first M, bonds, costing $19,959, and 21 Carter Co. bonds, costing $22,143.

Financial—We have been able, through the reduction in our stock of pig iron, to reduce bills payable $764,000 and increase our sales ledger balances $398,589 and our bills receivable $57,000, and in addition to purchase from the Inter-State Coal & Iron Co. for $187,500 the coal property, in fee simple, formerly covered by our Inman lease, and known as Inman mines. We purchased during the year new equipment amounting to $60,000 and real estate amounting to $30,000.

Purchase—The Inman purchase was of especial importance to us since during the lease we had expended over $200,000 in the construction of 175 coke ovens, 179 dwelling houses for miners, storehouses, etc., all of which would have had to be removed or disposed of on the expiration of the lease. The property still contains from 3,000,000 to 4,000,000 tons of minable coal, upon which, under the lease, we would have had to pay 10c. per ton royalty as same was mined. Now that we own this property, we confidently expect to save enough royalty on coal mined to pay the interest and principal on the purchase price, leaving the improvements available for use at our adjoining Linden mines.

Depreciation—The plants and equipment have been fully maintained, there having been charged against operating expenses for depreciation of plants, equipment, ore lands and coal lands, a total of $318,292, while additions and permanent improvements aggregated $149,503.

DIVIDENDS

Central R.R. of New Jersey—Regular quarterly dividend of 2% payable Feb. 2 to holders of record Jan. 23, also an extra of 2% payable Dec. 30 to holders of record Dec. 24.

Delaware, Lackawanna & Western Coal—Regular quarterly dividend of 2½% payable Jan. 15 to holders of record Dec. 31.

The Bond County Coal Co. (Illinois)—This company has recently offered $120,000 first mortgage, serial, 6% sinking fund, gold bonds. The total authorized issue is $500,000, the balance above that now offered being reserved for the acquisition of additional coal lands at a rate not to exceed $10 per acre.

After the Day's Work in an Anthracite Mine

18 Fifty-Ton Railroad Cars Loaded In a Day With One Baldwin-Westinghouse BARSTEEL Electric Mine Locomotive

understood the business
ground up.

MOTORMAN ESTABLISHES RECORD AT SCALP LEVEL

SPECIAL TO JOHNSTOWN DEMOCRAT.

SCALP LEVEL, Sept. 19—What is believed to be the highest record ever made in any section was made today in No. 1 mine of the Scalp Level Coal Mining company, one of the John Lochrie operations, when 18 steel cars were loaded by one motorman. The motorman who made the record output was Victor Gustasson. The foreman at No. 1 is William B. Wilson.

Eighteen steel cars of coal loaded in a single day with but one motorman is the highest run that has ever been made in this vicinity and it is believed that it has never been equalled anywhere.

Pure ... stamps needed ...

On this particular day they worked exactly nine hours and forty-five minutes. The only haulage equipment used was an eight-ton Baldwin-Westinghouse **Barsteel** Electric Locomotive, equipped with commutating-pole motors.

This locomotive, except for a few mine cars hauled from a dip from a point in the heading by a mule, did all the work, gathering the coal cars and hauling the same to the tipple.

When they stopped work in the evening the locomotive was inspected and found to be in first-class condition, in spite of the heavy work it performed. The motors were nearly as cool as when started in the morning.

Twelve mine cars, each loaded with two tons of coal, were hauled on each trip. The longest haul was made about 2500 feet from the face of first left to tipple and about the same distance from face of main heading to tipple. At two points in the mine for a distance of 400 feet the grades are 1½% against the loads.

Thirty-six trips were hauled, and it is estimated that at least two minutes were lost on each trip on account of the motor man waiting for empty cars outside.

There was no extra effort made this day to make a record. It was only an ordinary day's work, and it is believed that if they would make an extra effort, for any one day, this Baldwin-Westinghouse **BARSTEEL** Locomotive could gather and haul sufficient coal to at least load twenty-four steel cars.

Full information about Baldwin-Westinghouse BARSTEEL Electric Mine Locomotives can be obtained by addressing either company.

Advertising Keeps Prices Down

The Weekly Ad-Talk Page

"Go 'long"—you say, "prices haven't been doing anything but going up since the original Wise Dutchman bought Manhattan Island for $24 with a bottle of 'schnaps' thrown in for good will."

Right—but they haven't been going up as fast as they might, or as they would have gone had it not been for certain restraining factors.

When everybody lived on a farm, churned his own butter, smoked his own hams and, in between times, the women folks made home-spun, selling cost and cost of distribution didn't cut much figure. But today these two latter are big factors in determining the price you pay for your goods.

Anything that reduces selling cost and cost of distribution reduces selling price. *Advertising reduces selling costs—and you get the benefit.*

A page ad in Coal Age costs anywhere from forty to sixty-five dollars. It goes into every nook and corner of the coal mining world—into the hands of thousands of men who influence the purchase of mining equipment and supplies, just how many more than the actual circulation of the paper it is impossible to figure.

How much would the manufacturer have to pay to send his story to the same places via two-legged salesmen? No—how much would *you* have to pay?

Then, too, advertising has been, and still is, the very heart and life of competition. And, invariably, competition spells low prices, monopoly, high.

Read the ads and reap the benefits!

COAL AGE

Vol. 5 NEW YORK, JANUARY 17, 1914 No. 3

The Coal Miner

By Berton Braley

Written Expressly for Coal Age.

I

The engineer lays out the mine
An' tells just where the workin's goes,
An' when it comes to rule an' line
I guess he knows, I guess he knows,
The super'ntendent runs it all,
He's boss of every part an' whole,
But just the same I gets the call,
For I'm the guy who digs the coal!

II

The breaker boys, they does their share,
The pumpman does his duty, too,
An' then there's them that gives us air
An' hoists us up when we are through,
An' them that hauls the coal away,
An' them that keeps the workin' roll,
But don't forget ME, partner, say,
For I'm the guy who digs the coal!

III

It's me that drills where roofs is low,
Often lyin' on my side,
Until my body's achin' so
That nothin' keeps me there but pride,
It's me that takes the chance of damp
Or pickin' in a loaded hole,
It's me that wears the miner's lamp,
For I'm the guy who digs the coal!

IV

It's coal that makes the engines run,
It's coal that drives the ships at sea,
That gets the great world's labor done
An' warms the homes of you an' me,
It's coal that gives the strength to steam
An' I'm the grimy human mole,
That brings it out of vein an' seam,
Yes, I'm the guy that digs the coal!

V

They pats me on my sweatin' back
An' tells me I'm a high-class guy,
Although my face with dirt is black
An' I got coal dust in my eye,
But though they smile an' grin an' smirk
An' tell me I'm a "noble soul,"
I know my job is damn hard work,
For I'm the guy who digs the coal!

Trade Unions and the Law

By Henry R. Seager

SYNOPSIS—The suggestion is made that regulation of combinations is far better than prohibition of such bodies. An anti-combination law against wage earners would be unjust.

An incident of the present Colorado strike—the indictment of officials of the United Mine Workers by a Federal Grand Jury in Pueblo—again brings to the fore the relation of unions to the Sherman anti-trust law.

No single action of President Wilson has called forth more criticism than his approval, last June, of the sundry civic bill. This provided, among other things, that no part of the $300,000 appropriated for the enforcement of the anti-trust law should be used for the prosecution of labor organizations.

That such a method of limiting the activities of the Department of Justice was highly objectionable, few will deny. It does not appear, however, that the President was responsible either for the inception or for the execution of the plan. To avoid the necessity of changing—perhaps with serious consequences—a carefully prepared legislative program, he signed the bill in the exact form in which it had been passed by the previous Congress. He took pains, however, to qualify his approval by declaring that if it were possible for him to veto the "proviso," without vetoing the whole measure, he should unhesitatingly do so. Also, he pointed out that other funds at the disposal of the government made the limitation as regards this particular appropriation of no practical importance.

More important than the proper apportionment of praise and blame between the President and Congress for the legislation criticized, is the question whether the exemption of labor organizations from the operation of the anti-trust act is itself justifiable or desirable. Congress seems clearly disposed to accord such exemption. In the daily press the only intelligible reason given for this determination is the growing influence of the labor vote. If this were in truth the only motive behind the proposed policy, Colonel Harvey's declaration that the country seems destined soon to "face a determined struggle for class domination whose outcome every patriotic citizen must contemplate with the gravest foreboding" would seem fully warranted. But are there not better reasons for excepting labor organizations from the condemnation of the Sherman law than the fact that labor leaders in and out of Congress desire it?

Sherman Law Should Not Be Applied to All Combinations in Restraint of Trade

That the anti-trust act should not be applied indiscriminately to all combinations in restraint of trade is now generally agreed. After a good deal of hesitation, the Supreme Court of the United States has itself come to that conclusion, although it has not yet clearly indicated what the basis of discrimination, beyond the vague "rule of reason," is to be. Combinations of producers, using unfair methods to build up monopolies and then using their monopoly powers to extort unreasonably high profits from scattered and unorganized consumers, must certainly continue to fall under the condemnation of the law. From this class of clearly obnoxious and unlawful combinations there is a gradual gradation of combinations, like those of Western fruit growers attempting to maintain fair prices for their products in Eastern markets, which all would approve.

Shall we wait for the Supreme Court to work out a satisfactory classification of combinations, condemning the objectionable and upholding the "reasonable" or are there certain principles of condemnation which Congress may itself advantageously apply? I believe that there is one such principle that may at once be applied and that justifies the proposal to accord special treatment to labor organizations—a principle that has been embodied in English law since 1875 and that seems to have operated there in a way that has given general satisfaction.

Amid the complexities of the combination movement two distinct sets of economic relations are clearly separable. One concerns the dealing between the producers and consumers, or the sellers and buyers, of commodities; the other the dealings between employers and employees. Referring to the latter the British Conspiracy and Protection of Property Act of 1875 declared that in connection with trade disputes no agreement or combination to do, or to procure to be done, any act "shall be indictable as a conspiracy if such act committed by one person would not be punishable as a crime." In other words, combinations of wage-earners or of employers concerned with the questions of wages, hours, etc. that arise between them were expressly relieved from the condemnation which the common law applied to "combinations in restraint of trade."

British View Was That Combination Was Beneficial

It was believed that in this field combination instead of being an evil was on the whole beneficial. Wage-earners should be encouraged to combine—"trade union acts" were passed by the same Parliament—since combination was necessary to the protection of their interests. By combining on their side, employers could easily protect themselves from excessive demands on the part of the labor combinations. They should be allowed to combine with equal freedom. The interest of the public would, it was thought, be sufficiently safe-guarded if individuals were held to strict responsibility for their individual acts, the added penalties applying to conspiracies becoming operative only when the acts committed by combinations were in themselves criminal.

This cannot fairly be characterized as class legislation. The exemption applies as well to combinations of employers in connection with trade disputes as to combinations of employees. It is merely a recognition of the fact that the relations between employers and employees present one phase of the combination movement; the relations between producers and consumers, sellers and buyers, a different phase.

The proposal to exempt labor organizations from the operation of the anti-trust act is an application of this same principle. In its practical operation the anti-trust

Note—From "The Survey," Jan. 10, 1914.

act has frequently been applied to labor organizations; never, so far as I am aware, to employers' associations. Because it has never been turned against employers' associations, it has been assumed, perhaps too hastily, that they do not now come under the law. Those who advocate the exemption of labor organizations may easily clear their proposal of the charge of involving class legislation by following the example of the British parliament and causing the exemption to apply alike to employers' associations and labor organizations in respect to their mutual relations. This is what is really aimed at. The exclusion of employers' associations, which has been tacitly assumed, should be expressly added if labor organizations are to be excluded.

There are several arguments that may be urged in favor of this change. The anti-trust law has been held to prohibit the use of the boycott. There seems no reason, so far as the argument runs, why it should not also be held to prohibit the strike. Strikes certainly present combinations engaged in restraining trade as clearly as boycotts. But such an extension would bring our federal law back to the stage of development in which state laws were in the first quarter of the last century. Strikes and boycotts are to be deplored, no doubt; but does not the path of progress lie through developing combinations on both sides and arrangements for collective bargaining, conciliation and arbitration, that will make a resort to these weapons unnecessary? This is the well-nigh unanimous view of economists.

Capitalistic Combinations and Labor Organizations Are Quite Different

The normal procedure under the anti-trust act is a dissolution suit carried on at the instance of the government. Does anyone seriously advocate the dissolution, through judicial order, of our larger labor organizations? The American Federation of Labor has often been the target of attack for embittered employers, but, so far as I know, no one has gone so far as to petition the government to dissolve it, and for obvious reasons. This fact alone shows how different is the problem presented by the great capitalistic combinations and by labor organizations. The remedy that is applied as a matter of course to the one is not even thought of in connection with the other.

Finally, there is good ground for urging that the present law operates unfairly. The fact that it has not yet been invoked against a single employers' association, though frequently applied to labor organizations, is indirect evidence of this. Without any special machinery or publicity employers may readily come together, with business management concentrated as it now is, to agree on common policies with reference to employees. The political activities of the National Association of Manufacturers, revealed through the recent congressional inquiry, shows how far such associations may sometimes go without arousing suspicion of their purposes or methods. Thus effective combinations in restraint of trade may be maintained on the employers' side without attracting attention or giving rise to evidence that might later be utilized in legal actions.

The same is not true of wage-earners. Combined action for them means coming together in public meetings, publishing information in labor papers that may be widely read; in short, advertising as widely as possible what they propose to do and the means they propose to use in doing it. It is easy to prove the existence of the combination, if it amounts to anything. The consequence is that an anti-combination law may be enforced with little effort against wage-earners, scarcely at all against their employers. Feeling the injustice of this situation and their helplessness, the more hot-headed and ill-balanced among wage-earners are only too apt to turn to secret and lawless methods that are socially much more deplorable than any number of strikes and boycotts conducted openly and with proper regard for the public peace.

In this situation, not prohibition of combinations in connection with trade disputes, but regulation applied impartially to both sides by competent administrative officers would seem to be what is needed. If this should prove a first step toward the substitution of regulation for indiscriminate prohibition for combinations of all sorts, so much the better.

Progress of Coal Briquetting

By R. Schorr*

The increase in the world's coal output since 1900 amounts to over 62.4 per cent., which has been due mainly to the United States and to Germany, while the gain of Great Britain is but 14 per cent.

The production of coal briquettes has risen from 4¾ million tons in 1885 to 33 million tons in 1913 (36,366,000 sh. tons), equal to an increase of about 595 per cent. The rapid growth of the German lignite- (brown coal) briquetting industry has been mainly responsible for this, having furnished in 1912 over 19,050,000 metric tons. The total production of Germany in that year was 25.7 million metric or about 28.3 million short tons, equal to almost 78 per cent. of the world's output.

Belgium, France and England combined, manufactured 5.5 million metric tons, leaving for the balance of the world approximately 1.8 million metric tons.

Incomplete returns for 1913 indicate that the "official" briquette production of the German empire will be over 26.7 million metric tons, and allowing, conservatively, 1.3 million tons for the unlisted plants, which are operated by coal dealers, a total of 28 million metric tons (30,856,000 short tons) can be safely expected. England and France will also show gains, so that the briquette output of the world will probably reach 35.5 million metric tons, or 39,120,000 short tons in 1913.

There are about 600 briquetting plants in the world, employing close to 600 presses on bituminous coal and anthracite, and between 1400 and 1500 presses on lignite. Over 80 per cent. of the installations are in Germany.

The history of briquetting in the United States forms a marked contrast with the development of most of our other industries. Over 40 plants have been built, but less than half of this number is still in existence. The reported output was 218,443 short tons in 1911, and 230,064 short tons = 199,597 metric tons in 1912. There will be, however, a very material increase in 1913, due to the new plant at Berwind.

*San Francisco, Calif.

Underground Concrete Protective Work in Illinois Mines

By G. E. Lyman*

SYNOPSIS—Detailed description of an unusually elaborate undertaking in mine concreting on the part of the Madison Coal Corporation. Steel I-beams, reinforced concrete and concrete blocks were used according to varying conditions and loads. The application of concrete to underground conditions has not become sufficiently general yet to evolve the customary rules and formulas. The work here described is of particular interest in view of the fact it has stood the test of time.

Some few years ago the Madison Coal Corporation came in possession of the mine at present known as its No. 9 operation, its acquisition being incidental to an extensive coal land deal in Williamson and Franklin Counties, Ill. The property had been opened up by a local company whose limited capital, and mistaken ideas of economy, prevented their incurring the small additional expense necessary to obtain competent engineering supervision at that critical stage of development. The result was that the shaft pillars were robbed to such an extent, and so many openings made immediately around the bottom, that most energetic measures on the part of the new owners were required to save it.

The mine operates in the No. 6 seam, according to the Illinois Geological Survey's most recent nomenclature. The coal has an average thickness of 9 ft., the upper 18 in. of which is ordinarily left in during mining for roof protection; it is recovered as each working place is finished. Above is a shale and soft limestone roof, which disintegrates rapidly on exposure to the air and above this is the clay and soil, the total depth of cover being about 110 ft. Below the coal is from 6 to 18 in. of fireclay, resting on limestone. The presence of this limestone bottom so near the base of the coal, alone made it possible for the present owners to save the property from the destruction which would otherwise inevitably have followed as the result of the methods used in the original development.

*Mining engineer, the Madison Coal Corporation, Glen Carbon, Ill.

The Inadequate Pillars

As will be noted on the accompanying illustration the pillars between the main bottom and the north run-around range from 10 to 17 ft. in thickness. About 60 ft. east of the hoisting shaft on each side of the run-off for the empties, these pillars feathered out to narrow points, and were beginning to take weight so rapidly that the crushing of the coal could be readily observed. At the narrow edges of the pillars immediately north of and adjoining the hoisting shaft, the same crushing commenced, and the roof fell to such a height immediately adjoining the shaft as to endanger the timbering. Crushing of the coal also occurred near the pump room, where considerable gouging of the pillar had been done in an apparently aimless attempt to connect the two shafts below.

Iron Form for Blocks of Concrete Arch. Finished Blocks in the Background

Both run-arounds, where the empty trips are made up, had been depressed to give gravity operation for the empties, and the clay thus exposed to the air had crumbled away rapidly, leaving the face of the rib unsupported. In consequence of this, serious rashing of the coal occurred, although normally this coal will stand any length of time, and carry any weight below its crushing load without signs of rashing. I have observed workings abandoned twenty years in this field, where the pick marks of the original entry driving were plainly visible. The result of this serious rashing had been to widen the openings, allow the top coal to break, and by exposing the roof to the action of the air, had caused destructive and dangerous falls.

It will be apparent from foregoing that there were three distinct conditions to be provided for, each with its own individual remedy, as follows:

First—Protection of the base of the ribs where the fireclay had been eaten out from beneath.

Second—Protection of the roof at high falls.

Third—Most difficult and important of all, the reinforcement and strengthening of the pillars where the coal had commenced to crush through excessive roof pressure.

The first item was a comparatively simple matter to handle, and was effected in the manner indicated in the accompanying drawing. The loose and decomposed clay was removed, the excavation carried down to rock, and concrete placed as shown in the sketch, being carried up over the base of coal about one foot, and given a crown of 8 in., with a batter of one in four. The further disintegration of the fireclay thus being effectively stopped, and that already lost being replaced with a material

FIG.4 Detail of Concrete-Block Arch

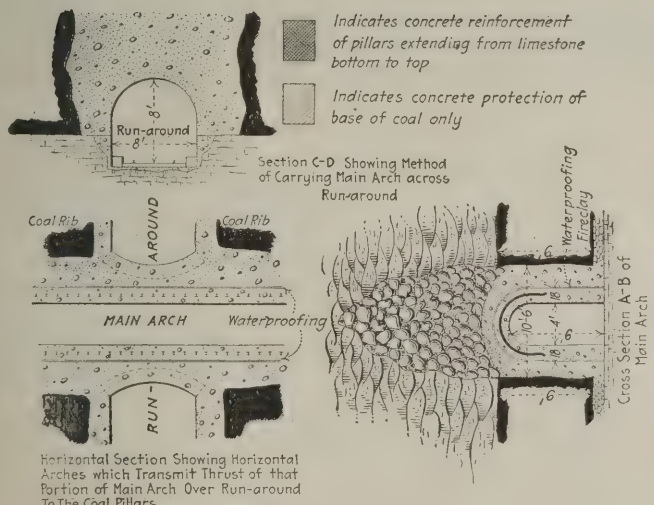

FIG.5 Sectional Views of Concrete Arch at Bottom Alongside Hoisting Shaft.

Details of Construction Used

strong enough to carry the weight, no further trouble from that source was experienced.

Steel I-Beam Roof Supports

The second item, roof protection, was handled in ordinary instances by using steel I-beams, of size and weight varying with the span, spacing them on 3-ft. centers. Where the ribs were in good shape the beams were mounted in hitches, which were then filled with concrete, giving them a solid bearing and effectually preventing them from turning. The beams were covered with 3-in. creosoted oak lagging, and the space between the lagging and roof filled with rock and clay, tamped tight. Experience has demonstrated that by thus shutting the air off the roof, there is little likelihood of further falling, and an excessive weight seldom comes on the beams. In cases where the rib was shattered, or out of line, concrete walls resting on the rock were resorted to. Fig. 3 illustrates the general construction employed.

The exact computation of the load eventually coming on beams under such conditions is manifestly an impossibility. It was decided to use beams which possess about a third more strength than that of an oak timber of the size which experience under similar conditions would lead to be selected for the same service. This strength of beam was figured as being based on the standard section, and in placing the order for the steel, beams of the same depth, but with a somewhat heavier web, were specified. The employment of this extra metal in the web (the critical part for this service) has the practical result of increasing the factor of safety and providing to some extent for unforeseen overloads, and the extra cost may be regarded as insurance against undue weakening through corrosion, a certain amount of which cannot be avoided during a long-lived mine, despite regular painting.

Where necessary to cross openings, such as other haulage ways, girders made of two or more heavy I-beams bolted together were employed. These girders were calculated for a strength sufficient to allow of doubling the number of I-beams carrying the roof, if ever such an emergency should arise, without exceeding the safe load on the girders.

Concrete Blocks

The entire empty side of the shaft bottom was treated in this manner, as well as the passage way between the two shafts, and a considerable portion of both run-a-rounds. No trouble has been experienced with any of this work, and it gives every indication of having permanently remedied conditions.

The roof of the west split for a distance of 200 ft.

from the bottom of the air shaft had fallen so high, and conditions indicated the probability of such an excessive load coming on whatever protection might be installed, that it was decided to use a concrete-block arch. Fig. 4 shows the dimensions of the arch and its individual blocks, and the manner of placing same in the entry. Forms were made of iron, accurately shaped according to plan, and the blocks made on the surface, where they were allowed to set thoroughly before taking below. A

I-Beams and Creosoted Oak Lagging during Erection

concrete consisting of one part portland cement, two parts sand, and four parts limestone, crushed to from ¼-in. to ¾-in. size, was used. The partitions in the form were so arranged as to allow of breaking joints as the successive rings of the arch were put in place below. As the blocks came from the forms, those in each set were numbered, so they might be erected again in the same order. Inasmuch as the perfection of the arch depends so greatly on the nicety of finish of the radial joints, great care was taken to have the planes leave the forms with a true and smooth surface.

The erection below was comparatively simple, though at times surrounding conditions made the work difficult, as well as dangerous. Where possible, continuous hitches were cut in the solid rib for the abutment blocks, and where necessary, concrete walls and foundations were employed. Portable wood centers were erected, and the numbered blocks laid in order on them. When four to six rings had been laid, the joints were grouted from above with cement mortar and pointed on the lower side, the centers moved ahead and operation repeated. Experience has shown, however, that the arch would stand apparently as well without grouting the joints as with it. The space above the arch was packed in tightly with rock and dirt to the roof.

The entire thrust of the arch being resisted by the solid pillars, its only chance of failure would be through crushing, which contingency, with a well prepared 1:2:4 mixture, is extremely remote. Before applying this method in coal that has any tendency to rash, concrete walls would have to be built along the rib to carry the load.

The accompanying halftones show a set of blocks in the form, which has been stood up to secure a better view, as well as several sets of finished blocks piled up to season before taking below. Another view shows the method of placing the blocks on the portable wood centers, and the method of filling in above, while a third shows a section of the finished work*.

*Some of these photos have already been published in previous articles (see "Coal Age," Vol. 4, pp. 619 and 640) on the Madison Corporation and also in "snap shots" (see Vol. 4, p. 813) and so have been omitted here.—Editor.

Renewing Pillars and Miscellaneous Details

The third item, strengthening the pillars where the coal had commenced to crush and break, was handled by filling in with solid concrete wherever possible. Concrete walls were run along the ribs, ranging in thickness from 18 in. to as much as 6 ft. in some extreme cases. The shaded portions of the bottom plat, Fig. 1, indicate the extent of this work, and will give a fair idea of the general conditions which had necessitated such an amount of this protection. One, two and four concrete, on account of its great crushing strength, was used in all this work. It was placed on the limestone bottom, and carried to the roof, at the same time furnishing support for the I-beams.

The especially bad place immediately north of the

Concrete Block Arch and Portable Wood Centers

hoisting shaft presented unusual difficulties, as it could not be filled in solid on account of being an indispensable passage way, while crossing it at right angles was the north run-around. It was decided to use here a solid concrete arch, of massive proportions, sufficient in strength to carry the dead weight of the entire strata above, if necessary; at this particular place the weight of cover over the coal is estimated at approximately six tons per square foot.

In Fig. 5 are sections of this piece of work, which really consists of three separate and distinct arch-elements. The main arch, with a clear passage way of 4 ft., begins at the north edge of the shaft, and extends across the run-around, and about 10 ft. on the other side to a firm anchorage in the pillar. Two secondary arches, with a span of 8 ft., carry the main arch across the run-around, while a third set of arches, placed horizontally, carry back to the solid pillar, the thrust of that portion of the main arch over the run-around.

Considerable water being present, and the space for working extremely limited, the main arch was built in two operations. The inner shell, 18 in. thick, was placed first, and then thoroughly coated with pitch; then came a layer of 2-ply Black Diamond roofing, made by the Barrett Mfg. Co., and a second coat of pitch. Another layer of roofing and a third coat of pitch were applied, and the remaining portion of the concrete laid, filling in solid to the ribs. Above, the arch was filled in to the roof.

The reinforcement consisted of 35-lb. rails, bent to shape and placed on 1-ft. centers as shown in vertical section, and rods were used lengthwise. The photographic view gives a fair idea of the appearance of the finished work, and plainly shows the arches over the run-around carrying the main arch over this space. The work has been in place over three years now, and stands today without a visible flaw. Although built in a very wet place, no sign of seepage has appeared. No further trouble has been experienced with the timbering of the hoisting shaft, and apparently the built-up ground alongside the shaft is as good as the original strata.

The work herein briefly described has resulted in saving the entire bottom development, and in adapting it fairly well to the requirements of a high-tonnage mine. Needless to say, it forms a conspicuous example of the expense and trouble often incurred, when opening a mine, through lack of carefully prepared plans and competent supervision in carrying them out.

Last Year's Anthracite Shipments

Final figures for 1913 show that the total shipments of anthracite coal from Pennsylvania last year were 69,069,628 tons. This is 5,459,050 tons more than in 1912, when the output was curtailed by a suspension in the spring, while a new agreement was being negotiated with the mine workers; but 884,669 tons less than in 1911, which was the record year for high production.

Total shipments of anthracite last month were 5,662,618 tons, as against 5,944,502 tons in December, 1912, a decrease of 281,884 tons. The amount of coal, on hand at tidewater shipping ports, decreased slightly, from 603,031 tons on Nov. 30, to 602,328 tons on Dec. 31.

The Lehigh Valley R.R. led in tonnage last month with 1,062,578 tons; the Philadelphia & Reading Ry. was second, with 1,058,723 tons; the Lackawanna was third with 839,384 tons; the Erie carried 709,431 tons; the Central Railroad of New Jersey, 663,395 tons; the Delaware & Hudson, 590,158 tons; the Pennsylvania, 546,976 tons; and the New York, Ontario & Western, 191,973 tons.

The examination of a mine to detect the presence of gas should be made by a competent man carrying only an approved safety lamp, within three hours of the time when the men enter the mine. Every working place should be visited and some mark left to indicate that the place has been examined. The condition of each working place should be noted in a special book which should be accessible to every underground employee.

Pennsylvania Bituminous Operators Hold Stormy Session

The Association of Bituminous Coal Operators of Central Pennsylvania held its regular Annual Meeting in the Betz Building, Philadelphia, Penn., Jan. 8. Almost the entire membership was in attendance. The tonnage represented amounted to approximately 70,000,000 tons per annum.

The meeting was not entirely harmonious, owing to the fact that there was a strong disposition on the part of a number of members to dissolve the Association for the reason that the United Mine Workers of America, District No. 2, allowed their members to violate the present scale agreement grossly, the argument being that it was useless to make a contract with a labor organization which willfully violated its contract at its convenience and which had apparently no officials connected with it who had power to enforce the terms of the contract.

Union Fails to Answer Association

This situation was considerably aggravated when the executive committee reported to the meeting that on Dec. 12, 1913, at a meeting held in Philadelphia, a communication was prepared and submitted to Patrick Gilday, President of District No. 2, United Mine Workers of America, calling attention to the numerous violations of the contract on the part of the miners and that the dissolution of the Association was seriously threatened by continuation of such conduct and that up to date no reply had been received by the Association other than a mere acknowledgment of the communication.

At the time the letter was addressed to President Gilday, closed-shop strikes were being enforced in the district, some of which not only still exist, but are being supported by the United Mine Workers of America, who furnish the striking miners with relief funds. The effort to smooth out the difficulty caused a motion to be made to refer the matter of dissolution to the executive board of the Association. This motion was defeated.

It was then suggested that under a recent decision of the United States courts labor organizations, such as the United Mine Workers of America, both as an organization and individually, could be held liable in damages resulting to the operators from these violations and particularly from the closing down of the mines to enforce the closed shop, which was prohibited by the terms of the contract.

One Hundred Strikes in Central Pennsylvania

It was reported to the Association that approximately one hundred strikes have occurred during the life of the contract, in violation thereof, a substantial number of which were called almost entirely to enforce the closed shop. It was only when the Association agreed to the appointment of a committee for the purpose of listing all the strikes that occurred in violation of the contract and ascertaining from each individual operator the damage suffered by reason thereof and to make report within 30 days of the result of such investigation, together with such recommendation as the committee deemed proper towards instituting actions for the recovery of damages, that the members of the Association agreed to submit the question to the executive board. This was considered quite a victory for the members who advocated the continuance of the Association, but when it came up to the executive board to take action, everybody was much surprised as a close vote resulted, seven voting against, and six for dissolution.

The meeting was in session from 10:30 a.m. until six o'clock p.m., excluding an hour's adjournment for lunch. The officers elected for the ensuing year are as follows:

President, B. M. Clark, Rochester & Pittsburg Coal & Iron Co.
Vice-president, C. H. Rowland, President Moshannon Coal Mining Co., Inc.
Secretary and Treasurer, W. R. Roberts.

Executive Committee

L. W. Robinson....	Pres. & Gen'l Mgr., The Rochester & Pittsburg Coal & Iron Co.....	Punxsutawney, Penn.

Committee on Coal and Coke

Under authority of the Board of Directors of the American Institute of Mining Engineers, President Rand has appointed a "Committee on Coal and Coke," to have charge of this branch of the Institute's activities. One of the main objects of the committee will be to secure for the Institute good papers on coal-mining subjects.

The committee is composed as follows:

H. M. Chance, Chairman, S. A. Taylor, Vice-Chairman,
S. D. Warriner, Vice-Chairman, F. W. C. Whyte, Vice-Chairman,
H. S. Fleming, Secretary, 1 Broadway, New York

Franklin Bache	Howard Eavenson	Floyd W. Parsons,
A. W. Belden,	Frank Haas,	Edward W. Parker,
S. W. Beyer,	F. A. Hill,	Edgar P. Pettebone,
William H. Blauvelt,	Charles F. Huber,	Erskine Ramsay
F. M. Chase	A. B. Jessup,	George S. Rice,
Clarence R. Claghorn,	Edwin Ludlow,	W. J. Richards,
E. H. Coxe,	W. J. Murray	Carl Scholz,
F. W. DeWolf,	R. Van A. Norris,	H. H. Stock,
Charles Enzian,	T. H. O'Brien,	Morris Williams.

Hailwood Lamp Approved by Belgian Government

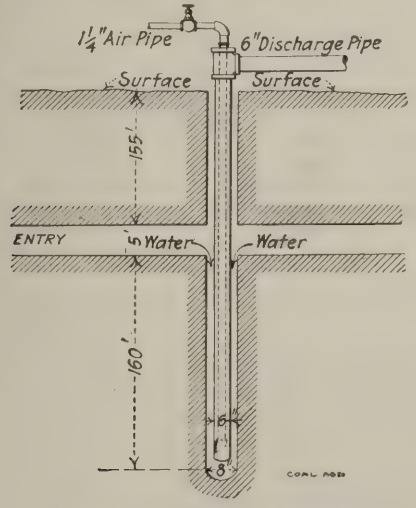
The Belgian government has this week signed the authorization approving of the use in Belgium of the Hailwood oil lamp, and also the Hailwood naphtha lamp, as manufactured by Ackroyd & Best, Ltd., of Pittsburgh, Penn.

The Belgian government tests are far more severe than those of many other governments, natural gas from the Grand Trait mines being employed in the gas tests. The lamp is subjected to the most explosive mixtures of this gas and air traveling at velocities of 5, 7, 9, 11 and 15 m. per sec.; the limiting velocities expressed in feet being 984 and 2590 ft. per min., respectively. The whole series of tests are repeated in horizontal currents, downwardly descending currents at an angle of 45 deg., upwardly ascending currents at an angle of 45 deg., vertical descending currents and vertical ascending currents so as to assure the safety of the lamp under all conditions, no matter how adverse.

Mine Drainage by Compressed Air

By A. D. Spears*

SYNOPSIS—When water broke into the mine from a "cave-in," it was removed by putting a bore hole down through a local dip in an entry and installing an air lift.



In December, 1912, water broke into the Crown Hill No. 1 mines, owned by the Clinton Coal Co., of Clinton, Ind. This was caused through the caving of an old room.

This mine is working the Indiana No. 5 bed of coal, which in this locality is about 160 ft. from the surface. This coalbed is generally dry, and in the mine in question the only pump installed was that for the sump at the bottom of the shaft. The bed has, however, several local dips, and fortunately the main west entry of the mine

THE AIR LIFT DISCHARGING MINE WATER AT THE SURFACE

starts in one of these. Since mines Nos. 1 and 2 are connected and Mine No. 3 is sunk to the No. 3 bed of coal, which is the one below that being worked by Nos. 1 and 2 mine, permanent arrangements had to be made for the removal of the incoming water.

CROSS-SECTION THROUGH MINE AND AIR LIFT

As pumps and pipe had to be ordered, the water soon caused the abandonment of the west part of the mine. It was the consensus of opinion, however, that the influx of water would soon stop, and only a 3-in. pipe line was laid for its removal, this extending for a distance of about 4000 ft. The 3-in. line proved inadequate to handle the water, and second and third 3-in. lines were subsequently laid. Rough measurements showed that the water was coming in at the rate of about 700 gal. per minute.

It was then decided to put down a drill hole, and discharge the water direct to the surface, and the air lift, as used in many city water plants, was suggested for this purpose.

A survey was made for the drill hole, as it was necessary that this should go through an entry, in order that the water might gain access to the hole. This drill hole was completed the latter part of January, 1913, and water was pumped continually 24 hours a day for four months. From the first day the air lift was started, the water was gradually lowered, but after about six weeks it was deemed advisable to put down another drill hole and install a second lift. The driller, however, had bad luck, and it took some time to finish the hole, and the water was pumped out before the job was completed. It is still necessary, however, to run one air lift 8 hours out of 24 in order to keep the water down.

The accompanying drawing illustrates this method of water removal. The system is most generally used in artesian or driven wells for raising either fresh or mineral waters from any depth. The only equipment necessary is two pipes in the hole and an air compressor. For the best results, somewhat over 50 per cent. submergence of the discharge pipe is required, but fairly good work can be done with only a 40 per cent. submersion.

*Clinton, Ind.

Recent Legal Decisions

Right to Rescind Purchase of Coal in Place—A purchase of all the coal in place in a tract of land cannot be rescinded on account of the coal area being smaller than was expected, if the land contains a substantial quantity. Nor may the purchaser rescind because of the non-existence of a particular bed. "In all cases of sale by the acre, there may be an abatement from the purchase price for deficiency in quantity * * * * Right to abatement or compensation for a deficiency in the case of a sale of land in gross stands upon the existence of a warranty of quantity or fraud and misrepresentation on the part of the vendor, respecting the quantity." (West Virginia Supreme Court of Appeals, Light vs. E. M. Grant & Co., 9 Southeastern Reporter 1011.)

Mining under 999-Year Lease as Invasion of Landowner's Rights—Measure of Damages—A lessee of the surface of land, although for 999 years, having no right to mine coal on the premises, the owner of the land is entitled to recover damages for removal of coal by the former, although the latter and his successors will not be entitled to possession of the land for several hundred years. The damages recoverable in any case for wrongful removal of coal is its value in place, if that value can be established by evidence; it being only when such proof cannot be made that the damages are measurable by the value of the coal at the pit's mouth. In computing the value of coal in place, its royalty or actual market as coal in place at the time must be considered, and not its prospective future value under changed conditions, if the coal is so located as to be marketable. (Pennsylvania Supreme Court, Trustees of Proprietors of Kingston vs. Lehigh Valley Coal Co., 88 Atlantic Reporter 763.)
COL. NOTE

Validity of Restriction on Buyer's Enjoyment of Property—Provision in a contract whereby a firm of retail coal dealers sold a teamster's outfit on condition that the buyer use the outfit exclusively in hauling coal for the sellers, is invalid, so far as it attempts to limit the buyer's title to the property, though the provision may be constued as an enforceable contract for the buyers' personal service in hauling for the sellers. (Iowa Supreme Court, Elijah & Winne vs. Mottinger, 142 Northwestern Reporter 1038.)

Discussion on Retarding Ventilation When Firing

SYNOPSIS—Explosion in a strong current of air—an incident. Reason for slowing down the fan before firing. Conditions and practice in Illinois mines discussed. History of the theory of retarding ventilation. A remarkable experiment in a Kansas mine. Effect of the supply of oxygen in mine workings. Effect of the size of mine openings. Study of the theory by the Bureau of Mines.

The president announced, in calling the meeting to order that the subject for discussion was Retarding Ventilation at Firing Time. He said, Pennsylvania does not have any retarded ventilation during firing time. I believe that Iowa, Kansas and Illinois practiced this method to some extent and I will ask Mr. Dunlop to tell us what he knows about that system.

An Incident

Mr. Dunlop (*Illinois*)—Eighteen years ago I was acting as mine manager when my attention was drawn to an explosion caused by the firing of a shot, in a new room that was in about twenty feet. There was a strong air current passing the room, on the entry. The entry was 6x8 ft. and the air was traveling with a velocity of 200 ft. per min. There were two shots fired in the room, but one did not do much work, while the other set fire to the gases, and caused the explosion. I had several explosions in the same place, and I came to the conclusion that the best thing to do was to slow down the fan during shooting time. This is a subject that an inspector must be very careful about. I would not post such a notice on the tipple. It don't apply to a mine that generates gas or has been known to generate gas.

Concluded to Slow Down Fan When Firing Shots

My conclusion after careful study was this: I felt that the reason for an explosion in a closed place of that kind was due to the gases from the explosion of the powder. I had a deal of trouble with some mine managers. Very often they said, we want more air. My experience, however, has been that the best way to avoid these explosions was to slow the fan down during shooting time, and I will say to you that, during all of my experience as inspector of mines, I have recommended this plan to all mine managers. On one occasion I recall Mr. Taylor and myself went to investigate an explosion, and I recommended this plan to the mine manager, to slow the fan down during shooting time; and they have never had any explosion since.

Now, the reason I have decided to slow the fan down is this: If you have a place just opening up, twenty feet or more, and a strong air current passing, the gases generated by the explosion of powder, do not get out of that room. The smoke is left against the wall. By retarding the ventilation these explosive gases have a better chance to expand and mix with the air; and the more they expand the less chance there is for an explosion; because they are diluted with the air, which renders the gases less explosive. Now, there is one other way, and that is to direct the air current by a curtain or brattice so as to get the gases out that are generated by the explosion of the powder. Then there will be less danger of an explosion from these generated gases. I had an explosion this year in January, nearly 600 ft. from the bottom of the downcast; and after investigation, I recommended to the superintendent to slow down his fan. All of these explosions to which I refer are in new mines and near the bottom of th downcast.

Illinois Conditions and Practice Discussed

Mr. McAllister (*Illinois*)—My theory about slowing down the fan is that if you have a slight explosion it will almost always set fire to coal dust; and for that reason, reducing the ventilation during shooting time is good; the gases become diluted with the air and are rendered less explosive.

Mr. McDermott (*Montana*)—What effect would slowing down the fan have on the coal dust that would be thrown into the air current by the shooting?

Mr. Dunlop—If you have an air current that is dusty, reducing the ventilation reduces the amount of dust in the air.

Mr. McDermott—And that is one of your reasons for advocating the reducing of the air current?

Mr. Dunlop—Yes.

Mr. Flynn (*Alabama*)—Is there any limit to the charges of powder used in the Illinois mines?

Mr. Dunlop—Yes, we have a law governing the amount of powder that may be placed in the hole.

Mr. Flynn—What is your limit?

Mr. Dunlop—Sixty inches of powder to every six feet, in thickness, of coal on a 1½-in. cartridge.

Mr. Flynn—How deep do they bore their holes?

Mr. Dunlop—Six and seven feet.

Mr. Parsons (*West Virginia*)—In the explosion that you said you had in January, you mentioned shooting rapidly two shots I think. Did you find any evidence of a blownout shot?

Mr. Dunlop—We found two holes that had been drilled there, and these holes were 6½ and 6¼ ft. One had blown out only a foot of coal and the other had just blown a little from the top. The coal was 4½ ft. in thickness.

Mr. Parsons—You say there were three shots fired in rapid succession. Now, it is impossible to have all three go off at the same time. Suppose, now, two of those shots went off first causing dust to be thrown into suspension in the air and later the third shot went off, would not this cause the dust to explode, even if you had no ventilation?

Mr. Dunlop—I think not.

Mr. Parsons—My explanation of the phenomena is that when the ventilating current is not moving the pressure is reduced and the gases are permitted to expand more freely and become diluted with the air, rendering the mixture harmless.

Mr. Muir (*West Virginia*)—Would not the same re-

Note—From the published Proceedings of the sixth annual meeting of the Mine Inspectors' Institute, U. S. A., held at Birmingham, Ala., June 10-13, 1913.

sults have been obtained if you should open up one or two breakthroughs and thus reduce the ventilation at the face?

Mr. Dunlop—That would have the same effect as slowing the fan. In reply to a question asked by Mr. Moses, Mr. Dunlop said that he had made these recommendations to a mine manager in Trenton County and had further recommended that the mine be sprinkled.

Mr. Parsons—Mr. Dunlop, what system of ventilation do you have, the blowing or the exhaust system?

Mr. Dunlop—The blowing system is generally used.

Mr. Parsons—If you were using a blower fan would not the reversing of the fan have the same effect in reducing the pressure?

Mr. Dunlop—I think not.

Mr. Pearce (*Indiana*)—In retarding the ventilation, is the idea to eliminate the initial cause of the explosion on the general explosion in the mine?

Mr. Dunlop—It is the initial explosion.

Mr. Moses (*Illinois*)—Have you known of an explosion in an Illinois mine caused by a shot that has done its work properly?

Mr. Dunlop—I remember one or two but they were local and covered very little territory.

Mr. Moses—Did you investigate the explosion at Rend City?

Mr. Dunlop—I am not sure if I did or not.

Mr. Moses—The point I am trying to make is this: You seem to give all the credit of the prevention of explosions, to retarded ventilation; and, to my mind, you do more in retarding ventilation to produce explosions.

Mr. Dunlop—I have done that for sixteen years: We have inspectors in Illinois that do not agree with the principle of retarding ventilation during firing time and I would not advocate this plan in mines in which there are explosive gases generated.

Explosions Occur Where Ventilation Is Poor

Mr. Little (*Illinois*)—Most all of the explosions we have had, in Illinois, have occurred in places where the ventilation was poor; and these explosions were caused by the excessive use of powder or misplaced holes. We have, in Illinois, what are called "shotfirers"; and we have a large number of foreign employees. The shotfirer is not supposed to know what is in the holes; he does not charge them and he fires the shots in rapid succession. In this rapid shooting, there is liberated a large quantity of gas. The shotfirer goes into a place that is beyond the last open crosscut and fires three shots, one of which may have been misplaced and the misplaced shot throws out fire and ignites the coal dust and gases that have been liberated by previous shots.

Mr. McAllister—In the explosion to which Mr. Dunlop refers there were only three shots fired that night; there was much dust; the coal was about 8 ft. thick; the three shots fired in that room all did their proper work. We traced the flame down to the mouth of the room. The force of the explosion blew the cars up into the tower of the shaft. We made a thorough examination after this explosion and did not find a trace of explosive gas. At another mine, near Springfield, at least 1500 lb. of powder is exploded in less than three hours.

Mr. Martin (*West Virginia*)—How far were these shots from the entry?

Mr. McAllister—About 200 feet.

Mr. Martin—Was the air current turned into this room?

Mr. McAllister—There was no evidence of the air being conducted up into the room; the shots were apparently fired in stagnant air.

Mr. Moses—Did that explosion occur on the first of the air or on the return current?

Mr. McAllister—On the return of the air.

The History of Retarding Ventilation

Mr. Beard (*New York*)—I would like to give a little of the history of the suggestion of closing down the fan at firing time. Our records are not complete; but the first mention of the subject, to my knowledge, and the first experiments ever made were by John Verner, a former mine inspector of Iowa, back in 1886, and a charter member of this Institute. It was after the Cedar Mine explosion, just west of Albia, Iowa. Mine Inspectors Thomas Binks and John Verner, together with Joe. Richardson, the mine boss, and myself went into that mine, after the explosion. It was found that the explosion occurred on the 15th or 16th west off the main south entry. On our way out, we had gone about half way to the shaft when John Verner stopped Richardson, the mine foreman, and said: "Joe, you want to open the shutter in this regulator, just before firing, or slow down the fan. By doing that you will short-circuit some of your air and have less circulation in the workings and there will be less risk of an explosion." I took exception to his theory and told Mr. Richardson that he did not want to interfere with his ventilation. That was the beginning of it.

Since that time Mr. Verner has continued to advocate that theory in the West. It has spread into Illinois and down into Kansas and Oklahoma; but whether they accepted and followed it in Oklahoma, I could not say. I think they did not. In Kansas it seems to have gotten a great hold; and this past winter we took the matter up in Coal Age, submitting it for discussion. There were three or four remarkable letters from a man by the name of McAllister, a mine foreman at the time, in Kansas. His statements were so remarkable that after holding his letters several weeks I thought it would be a good thing to publish them for what they were worth. He claimed that the slowing down of the fan and even sealing up the upcast shaft, which retained in the mine the products of combustion due to the explosion of the powder, reduced the oxygen in the air current and rendered those gases less explosive.

Experiment in a Kansas Mine

Mr. McAllister went so far as to state what any of us would be strongly tempted to say was an untruth. He said he took a keg of powder and went down into the mine, in company with another fireboss; and together they fired 27 shots. They had previously placed the keg of powder in a heading and covered it over with a mound of slack. They fired this immediately after the 27 shots while he and the fireboss were in the mine, and they came out alive. Such a statement is beyond belief and would be pronounced by many as not worthy of consideration. The discussion in Coal Age, however, was valuable. We don't any of us realize as we should what value there is in the arguments of the other side. Mr. Verner is right to the extent that a reduction in the velocity of the air current when firing shots reduces

the tendency to an explosion. The discussion developed this point, and I think there is some truth there, but just how far it can be applied, I would not care to say. I am convinced of one thing, however, that there can be too much air at the time of firing. At any rate, the matter was put up as a suggestion to the Bureau of Mines and we asked them to conduct experiments along those lines.

The letters and statements to which I have referred were corroborated by the mine superintendent of one of the large mines in Kansas, who stated that any time the Bureau of Mines desired to test the matter he would throw his mines open in any and every way possible. It seemed as if there must be some conditions in Mr. McAllister's experiments with which we are not thoroughly familiar; and while I would not, for a moment, advocate tampering with the ventilation of a mine, at the same time, I must admit that it has been done successfully in a great many cases. Mr. Dunlop has just given some instances. I regard it as a question to be discussed and tested out by experiment.

Effect of Oxygen Supply

Mr. Flynn—Don't you think that the supply of oxygen at the time of the explosion has a great deal to do with the intensity of the explosion?

Mr. Beard—I do most certainly.

Mr. Flynn—Then you think that if there is less oxygen in the air at the time of firing shots there will be less liability of an explosion.

Mr. Beard—Yes, but when you have reduced the oxygen content to the point where this condition would obtain, the men might not be able to live in such an atmosphere.

Mr. Flynn—Do the same conditions obtain concerning a coal-dust explosion in a mine, as obtain in the case of a fire in a stove, by reason of the supply of oxygen? Shut off the draft in a stove and the fire goes out.

Mr. Beard—No, I think not. The two cases are quite different. In the mines, under any ordinary mining conditions, we understand that there is always enough oxygen to start an explosion of gas or dust. I cannot conceive of a mining condition without sufficient oxygen to start the explosion. There is no similarity in the comparison.

Mr. Flynn—Then you think that you can have an explosion and a propagation of the explosion with a low oxygen content as with a high percentage of oxygen.

Mr. Beard—At the initial moment of an explosion, I believe there is always enough oxygen in the mine air, under working conditions, to make that explosion possible. Now, the question of a strong draft will not only bring with it much dust but also a fresh supply of oxygen that will propagate the explosion through the mine. It is in that manner that the question of draft affects the explosion. But to say that to shut off the air current entirely and then expect to fire a number of shots in the mine, without causing an explosion, I think is open to question and grave doubt.

Mr. Flynn—Is it not a fact that the effect of slowing the fan would be to reduce the oxygen supply in the mine?

Mr. Beard—Yes.

Mr. Martin—Do you believe that at the initial point of an explosion there is a high velocity of the air?

Mr. Beard—Undoubtedly.

Mr. Martin—You stated that you believe a high velocity had a tendency to cause a mine explosion?

Mr. Beard—Yes, a high velocity of the air current passing the shot.

Mr. Martin—Don't you think that if a shot was fired, the air current traveling at a high velocity would take away the gases produced by the shot?

Mr. Beard—Yes, and supply live oxygen and dust to the atmosphere at the working face.

Mr. Cartlidge (*Illinois*)—In reading over Mr. McAllister's articles I somehow got the impression that he did not stop the fan. I don't know that the article said that, but I got the impression that he sealed up the shaft and allowed the fan to continue against a dead end.

Mr. Beard—I think you are wrong there. I think he stopped the fan and sealed the shaft, at first, at least.

Mr. Cartlidge—Here is the impression that I got: In one of his articles he stated that the superintendent wanted to shut down the fan, and close the downcast and he immediately said they would have an explosion and refused to have anything to do with it. Superintendent went ahead and had an explosion.

Mr. Beard—I think your impression is wrong.

Effect of Size of Workings

Mr. Bolt (*Illinois*)—Suppose, Mr. Beard, in a mine where they have a large area, or in other words, where they drive the entry 16 ft. wide and the roms 30 ft. wide and shoot, perhaps, 250 shots at one firing, would it not be absolutely impossible to close down the fan when firing these shots and have enough oxygen to get complete combustion in every instance?

Mr. Beard—I think it would be doubtful.

Mr. Bolt—One other question: Would it not be advantageous to retard the ventilation at firing time, provided the conditions were normal in the mine?

Mr. Beard—I am inclined to think it would be in some cases; but as I said before, in other cases, I think it would be dangerous; I would say that in a thin vein with narrow openings, the danger is greater than in a wide open mine, such as you mention.

Mr. Bolt—But Mr. Beard, most of the severe explosions that have occurred, in Illinois, in the last five or six years, have been in practically new mines where there was an abundance of ventilation.

Mr. Beard—Yes, and you must remember that those new mines are rushing out a large amount of coal and have a comparatively small area working which means a high velocity of the air current and danger.

Mr. Bolt—Why would it not be a still greater advantage where the area is small and the number of shots limited, to close down the fan entirely, and have less oxygen in the mine?

Mr. Beard—In restricted workings such as you describe, I think the safer plan is to keep the air moving at a reduced velocity.

Mr. Bolt—Then you cannot always apply the same rule to all conditions. You must apply a rule that suggests itself to conditions. There is no fixed rule. It would be dangerous to say either close down the fan or decrease its speed.

Mr. Beard—I think that is correct.

Mr. Dunlop—During the month of September, 1912, Prof. Young, of Kansas, who is, perhaps well known to most of our members, wrote an article claiming that you

cannot have too much air in a mine. He was in the mine where we had an explosion, getting samples of dust for the Illinois Geological Survey. Now, as I said, in this very mine an explosion occurred in January. The superintendent was with us; and they had just been putting in a new fan and the superintendent said: "Well, John, I guess when I get that fan started I will have to reduce the speed during shooting time." I said, "I don't think so; because I knew how Mr. Young felt about it. But, the superintendent knew that I believed as Mr. Verner had said, that we must reduce the ventilation during the time of firing shots, and it rather surprised him that I made that statement; and I will say to you now, that the speed of that fan never was reduced, until the explosion occurred in January. It may be a coincidence; but that actually occurred. Since that time, the speed of the fan has been reduced, during firing time.

The Bureau of Mines Studying the Problem

Mr. Paul (*Pennsylvania*)—I have read the articles which have appeared in the public press and journals concerning the effectiveness of reducing ventilation during firing time; and particularly have I noted and studied the articles contributed, in Coal Age, by Mr. McAllister, of Kansas. Probably a year or a year and a half prior to the appearance of these articles in Coal Age, I had the opportunity to peruse the original manuscript. There were some statements made in that article that caused me to question the correctness of the facts as stated by Mr. McAllister. One thing in particular aroused my suspicion. He stated that in one of the mines in which an explosion had occurred he immediately descended the shaft, and found in the center of the entry, a current of pure air, and following that current of air he rescued some men. In all of my experiences in mines, following explosions, I have never found a column of pure air, so located, or air in the center of an entry, which varied much from the air against the roof or on the bottom.

In regard to reducing ventilation during firing time, we have had statements from Mr. Verner, of Iowa, in regard to the effect of retarding ventilation at firing time. And Mr. Rhys, one of the present mine inspectors of that state, shows there has been no prevention of explosions by reason of retarding the ventilation. In Kansas, where they practice retarding the ventilation, we have no facts available with regard to explosions occurring when they did not reduce the ventilation. We do know that Kansas has had a large number of explosions within recent years; a great many in mines where they have had retarded ventilation, resulting in a small loss of life.

The question resolves itself into one requiring the study of phenomena attending the retarding of ventilation. Some investigation is now being made by the Bureau with a view of determining whether or not there is any efficacy in retarding ventilation during firing time. A statement was recently made by a Liverpool professor, in which he advocated reducing the oxygen content of the mine air, as a means of preventing explosions. That theory has been largely criticized and I believe Coal Age has written a plausible and just criticism of it. Experiments made in the laboratory of the Bureau of Mines have not confirmed all the statements made by that professor in regard to the diminution of oxygen in the air. I speak of this since it has appeared in public print. Experiments are now under way at Pittsburgh to determine the effect of diminishing the quantity of oxygen in the air with regard to the propagation of a dust explosion, and I regret on this occasion that our Mr. Hall is not present to give you a summary of some of the preliminary tests that have been made. The statements I make in regard to those tests, are subject to his verification later; but I believe he has found by diminishing the quantity of oxygen in the air to about 2 per cent. below the normal content, a dust explosion is not propagated, owing to the lack of sufficient oxygen to furnish complete combustion.

It seems to me, therefore, that this discussion resolves itself into a technical question concerning the oxygen content of the mine atmosphere. Another feature of the question might be the agitation of the mine air. It is found in laboratory experiments on a large scale, that if you have a mixture of air and explosive gas in the proportion in which it creates the most violent explosion, the air and gas being thoroughly mixed and in a quiescent state, and ignite it, you get a low explosive force; but if you agitate the same mixture of gas and air, before igniting it, you will get a much more violent explosion.

So far as the effect of retarding the air current, in dust explosions, the mere fact that you have retarded the air current and prevented the agitation of the air may be responsible for the lack of propagation of the explosion; but this is a conjecture since it has not as yet been proven by experiments, on a large scale. Analyses taken throughout the country show that it requires an extremely poorly ventilated mine to carry an oxygen content much less than the normal amount in the atmosphere.

Commendation

The following letter comes to us from one of the assistant firebosses in a mine requiring careful inspection. It comes from one who is evidently appreciative not only of the efforts of his employers to carry out the mining law in respect to the safety of the mine; but likewise of the thorough work of the state mine inspector in that district. Coal Age congratulates both the management of the mine and the inspector on the result.

"I want to commend our mine inspector for the thorough manner in which he regularly performs his work, in seeing that the requirements of the mining law are met in respect to the safety of lives and property. Anyone who has observed Mine Inspector Elias Phillips, on his rounds of inspection in the mines, would be satisfied that he is a credit to the inspection department of the state. Unlike some inspectors I have seen, who never leave the main entries, Mr. Phillips inspects every hole and corner thoroughly, and makes his inspection like one of the assistant foremen or the mine foreman himself.

"I would say, also, to the credit of our general superintendent and our mine foreman, that they comply with every order of the inspector to the best of their ability. This mine is one of the hardest mines to handle, in the state, because of a difficult roof and much water. But, as a result of this good work and coöperation, I am proud to say only one fatal accident has occurred in this mine during the past year."

Details of Mining Methods

By W. H. Grady*

SYNOPSIS—Explains the difficulties in drawing pillars after they have been allowed to stand and details some of the precautions which should be taken to obtain safety and maximum recovery. A preliminary statement showing the defects of room-and-pillar methods as are quite frequently adopted.

No attempt will be made in this paper to outline the details of all the methods of mining coal; rather it is my desire to refer to the room-and-pillar method of mining, which, in its various modifications, may be said to be the prevailing method of extracting coal in this country. However, some longwall mining is done, especially through the Middle West, and, as the market value of coal rises, it is quite probable that the latter method will become more general in the thinner seams of coal, which cannot be mined with profit.

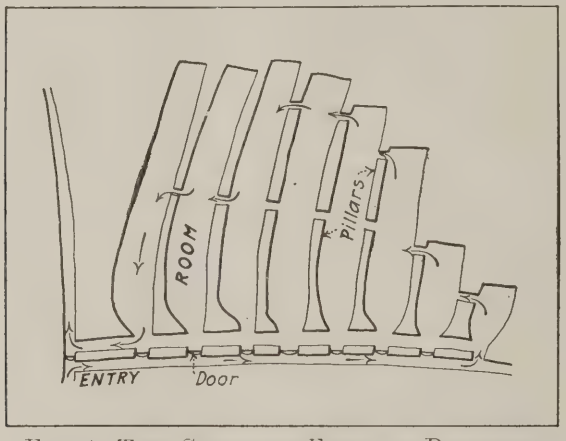


Fig. 1. The Simplest Form of Room-and-Pillar Work—Unsafe and Wasteful

First Cost Versus Final Cost

In the early days of mining in this country, that system which yielded an output at a minimum cost under conditions then existing, was adopted without any thought of how the remaining coal in the ground was to be mined, and the same influencing factor is dominating the methods of operators in some of the mines of today. Coal was little known, its uses were limited, the methods of mining were crude, so that the operators, all of whom were of limited capital, did not seek for what would be the most economical method in the long run, but for that plan by which they could mine coal cheaply and quickly at the commencement of the operation.

As a result large areas were opened and not only were the long-standing pillars subjected to the deteriorating effects of the air but they were constantly injured by the overlying weight. These methods had but one favorable feature and that was but temporary, for though the coal could under the slipshod system, then in use, be mined cheaply, there was a subsequent loss of coal from "V"-shaped robbing, much crushing of pillars, many creeps, large expense from the cleaning up of falls, increased timbering and duplicate trackwork. So that the time is approaching, in fact its advent is already announced, at many mines, when the cost of mining coal in the old workings will be much higher than it now is. In addition, much valuable coal in pillars will be entirely lost.

A Percentage Recovery of 90 Per Cent. without Materially Increased Cost

To avoid these losses operators have realized that they must use methods which make mining costs almost prohibitive or else a system by which only 60 to 65 per cent.

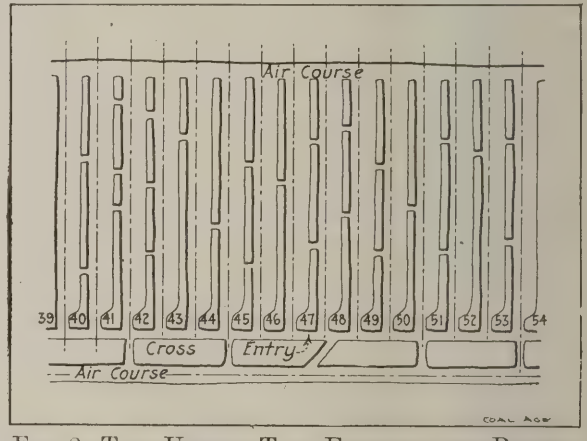

Fig. 2. The Use of Two Entries and Rooms Driven on Sights

of the coal is recovered. Facing such alternatives, they are proud to have lighted on a modification of the old method which differs from it only in detail, and yet gives them a recovery of 85 to 95 per cent., or even more.

That such a great difference in the percentage recovery has been brought about without materially increasing the cost per ton, is all the more to the credit of coal-mining men and places them among true conservationists.

The Simplest System

The simplest form of the room-and-pillar system of mining, may be said to consist entirely of rooms turned off an entry, leaving a pillar between each room turned, as in Fig. 1. This method may be said to yield the greatest number of working places per unit length of entry. Fig. 1 is a reproduction of actual mine workings which came under my observation in the last few years and represents room-and-pillar work in its most dangerous form.

A later step was to drive two entries with rooms off each. This insured somewhat better ventilation. But, as will be shown later, this method will not permit the recovery of the maximum amount of coal at a minimum mining cost.

Where much coal is to be handled, the double-entry system with rooms off both entries presents operating difficulties which are sought to be overcome by driving rooms off one entry, using it as a return airway and haulage road and reserving the other entry as an intake for

*Chief mine inspector, Pocahontas Coal & Coke Co., 133 Giles St., Bluefield, Va.

Note—First part of an article entitled "Some Details of Mining Methods with Special Reference to the Maximum of Recovery" read before the West Virginia Coal Mining Institute, Dec. 9, 1913.

air only. Fig. 2, an example of this method, is a step in the right direction and a great improvement, but for large properties where mining is done extensively, a further improvement must be made.

Leaving Pillars Till Mine Is Finished

Formerly, entries were driven and worked by one of the methods above, and the greater part of a property was developed, before the work of removing the pillars began. Robbing pillars brought on new difficulties which were sometimes calamitous. The thin pillars, became so strained, often before robbing had been attempted, that they could no longer support the mountain or overburden and they failed by crushing at the point of greatest weakness so that the mountain or overburden tottered.

Once "tottering," "squeezing," or "creeping" or all three actions together sets in, pillar after pillar is crushed, the destruction spreading, sometimes with the rapidity of a prairie fire. Until sufficient barriers or areas of solid coal are reached, capable of counteracting this now tremendous dynamic force, no available power can stop it. Sometimes such a squeeze will destroy acres

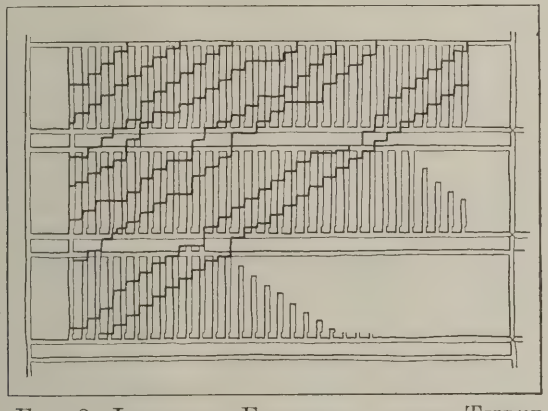

Fig. 3. Lines of Fracture across Three Headings Worked as a Unit by Room-and-Pillar Retreating Method

of pillar coal and render impossible or expensive the mining of other coal lying beyond the affected area which is only accessible through the squeezed territory.

I have in mind an instance where over 75 acres of pillars were crushed so badly, in a period of less than two weeks time, that all hope of ever recovering them was abandoned. Another example of the toll a squeeze demands is the loss of life in the Twin Shaft disaster in the Wyoming region of the Pennsylvania anthracite field, where men were buried alive, whose bodies have never been recovered.

These difficulties and the great expense, attendant on relaying track and cleaning up slate falls with which the pillars were so frequently congested, brought a further change in the room-and-pillar method of mining, whereby the pillars could be more economically extracted, and in the event of a squeeze starting it could be controlled. It developed what is known as the "panel system" of room-and-pillar work as shown in Fig. 3.

This panel system may be said to represent the better practice of today. It is pertinent, therefore, to know what size of panel, width of entries, width and depth of rooms and size of pillars will insure against squeezes and yield the maximum of recovery at a minimum of expenditure.

The overlying burden is often thought to be the determining factor in regard to room widths and size of pillars, but in general it determines the *minimum* size of pillars and the *maximum* width of room only, which may be materially different from the size of pillar-and-room width as determined by other factors.

However, a full knowledge of the manner in which the weight of the roof tends to act should be thoroughly understood in order that we may determine approximately what will happen when the coal is being worked and the pillars extracted. For an excellent analysis of this question of roof weights and action, I would refer to the papers of H. W. G. Halbaum, entitled "The Action, Influence and Control of the Roof;" and, "Great Planes of Strain in the Absolute Roof of Mines." These papers appeared in the "Transactions" of the North of England Institute of Mining and Mechanical Engineers.

Halbaum's Hypothesis

Briefly there are two forces acting which compose the total roof action, a vertical force acting downward and a horizontal force acting opposite to the direction in

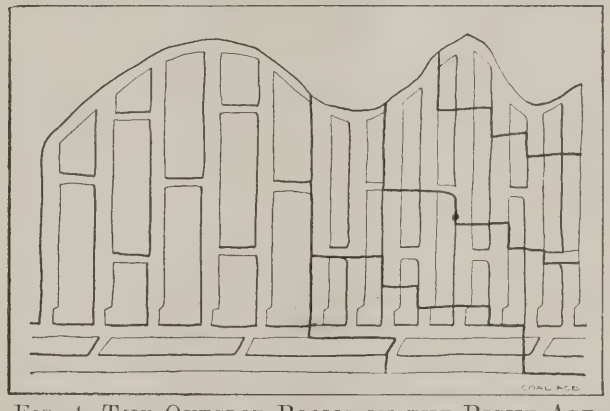

Fig. 4. The Outcrop Rooms on the Right Are Sure to Fill with Slate, and Pillars Are Too Narrow to Split or Slab

which the workings are advancing. The resultant of these two forces is in a direction from over the solid coal toward the excavated area and tends to break the roof over the pillars so that one must be constantly alert for such action.

When the pillars are not mined clean, the strata overlying the excavated area are not allowed to break and rest freely on the bottom.

The tendency often is for the roof not to break but to sag gradually until at some distant point in the gob, it reaches the bottom. This gradual subsidence of the roof often will be so severe as to crush the end of the pillars next to the gob and prevent miners from getting cars to the point where they desire to load them, thus causing more incomplete pillar extraction. Often when this stage is reached it will be found that neither the setting of props nor their removal will affect the action of the roof.

In general it may be said that so far as the weight of the roof is concerned, the pillars should be of the following dimensions:

PILLARS FOR VARIOUS DEPTHS

Depth of cover, ft.	Width of pillars, ft.	Width of rooms, ft.
300	15	20
500	20	20
700	25	20
900	30	20
1200	35	20

Why Uniform Pillars Are Used Despite Varying Cover

Ordinarily the pillars and rooms, within certain limits, are made of uniform size, in the same mine or group of mines, notwithstanding the variations in cover, which may be encountered in mining.

For example, the size of the room pillars required under a ravine where the cover is only 150 ft. thick should be 15x80 ft. and underneath the mountain top where the cover is 475 ft., the size of the pillars should be 20x 80 ft. As a matter of fact, all are somewhat larger than the maximum size required according to the table, because the pillars should not only be large enough to support the weight of the roof while the rooms are being driven, but also at the time the pillars are being robbed back.

To change room spacing would involve a further complication, conducive to losses of coal, in that the small pillars would be robbed back more quickly than the larger ones and an irregular breakline would result, with some pillars extending far back into the gob. These would be inevitably crushed.

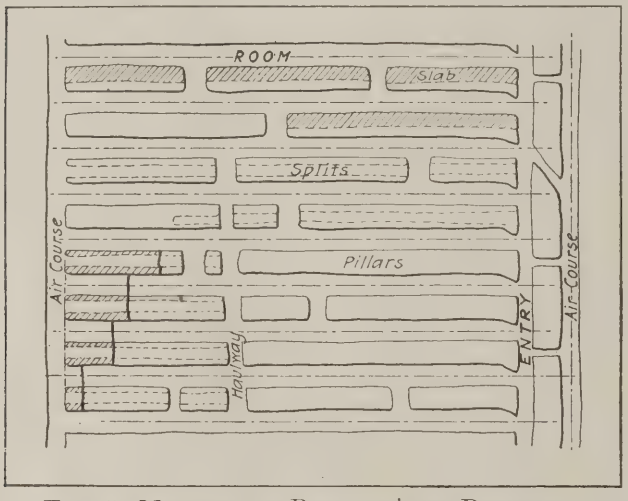

Fig. 5. Method of Recovery of Pillars by Slabbing and Splitting. In Lower Five Rooms the Splitting Is to Be Done in Two or More Lifts from Counter Haulways

Where Pressure Is Light, the Pillars and Pillar-Footings Are Usually Weak

An error that is sometimes made in drift mining is to suppose that because workings are near the outcrop and the cover light, wide rooms on narrow centers may be driven. While it is true that the cover is light, as a rule it is so badly weathered that it has little strength and before mining has proceeded very far the rooms will become congested with slate falls, and splitting of the pillars will become imperative. The dead weight resting on the wings of the pillars soon crushes them and a squeeze may result, causing large losses of coal. Fig. 4 illustrates two systems of crop working with different room spacing.

Large Pillars and Narrow Rooms Needed under Both Weak and Strong Tops

Probably no one factor contributes more to determine the working size of the pillars than the nature of the top and bottom immediately adjacent to the coal. Their behavior, especially that of the top, under the forces acting during robbing, the weathering effects of the air, the effect of temperature changes upon the top and its ability to withstand tension, compression and shear are all of prime importance.

If the roof is a material which cannot resist these agencies, it will fall very probably before the pillars are robbed, so that cleaning up slate falls becomes a daily occurence, and so great are the delays and expense occasioned, that the cost becomes prohibitive; incomplete mining is certain; a squeeze occurs and much good coal is lost.

On the other hand, if the top is a strong sandstone the impression is common that wide rooms may be driven and only small pillars are necessary. Because of the great strength of the top and the absence of slate falls, the time of starting the robbing is a matter that receives very little attention.

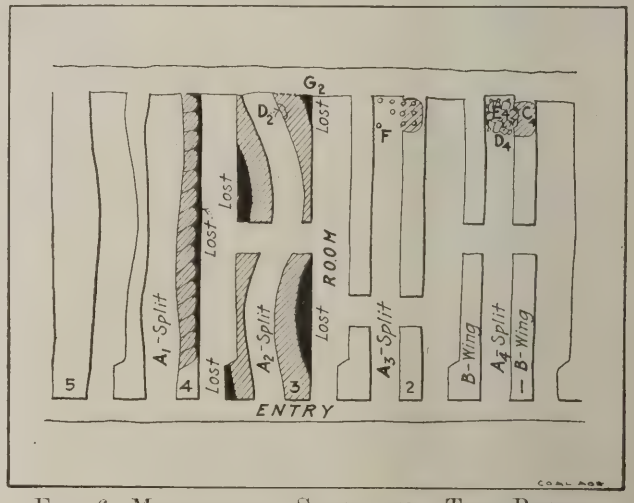

Fig. 6. Methods of Splitting. The Black Areas Show Coal Lost When Roadways Are Not Straight. When Roof Falls against Standing Ribs, the Roof Rock Mixes with the Coal

Under either strong or weak top, large pillars and narrow rooms are imperative and the robbing should follow within a reasonably short time after completion of the room.

Cleaning Out Pillars in Old Workings

Fig. 5 is an example of an honest effort to obtain the coal in the pillars, when, by reason of slate falls or crushing, the pillars cannot be drawn back in the ordinary way. Wide deep rooms were driven on narrow centers, under very weak top which was known not to stand weathering well and fell for a height of from 5 to 15 ft. and even more. The rooms were driven during the years 1898-99 and under the system then practiced at the mine, robbing did not follow. Extracting the pillars was started in the year 1907.

All the rooms were congested with slate falls and the work was started by slabbing. By this method the miner was continually retreating from his solid work and placing himself in danger from the bad roof overhead. When the miner was ready to come back with the remaining portion of the pillar, it was often found to be so badly

crushed that only a partial recovery could be obtained and frequently slate falls would close the space in.

Splitting the pillar from the entry to the aircourse above proved to be a failure because the wings could not support the load coming upon them and the timber cost of attempting to recover the pillars in this way became prohibitive. Finally in an honest effort to recover the coal, if at all possible, counter haulways were driven across the pillars and the falls met in crossing the rooms were cleaned up.

Counters and Short Splits

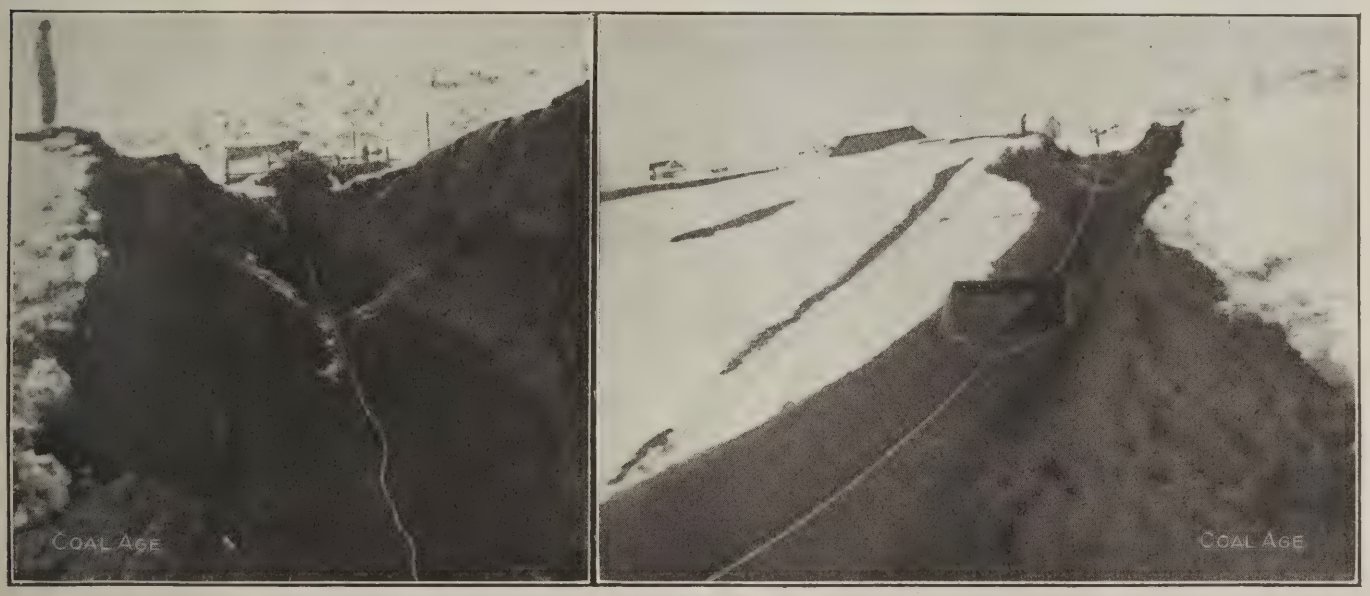
Then short splits were driven up the pillars from the counter haulway, and the wings quickly robbed back before they became so weakened that their recovery was impossible. This resulted in the maximum of recovery under the circumstances, but the expenditure for handling slate falls, relaying track, timbering, and other items made this coal more than twice as expensive as the coal produced in normal parts of the mine.

If the roof is weak so that "robbing falls" occur quickly after the removal of the coal, a maximum recovery at minimum cost can never be obtained by splitting the pillars and loading out the wings. It is easy to see that the "robbing falls" resulting from the removal of one wing, will prevent the complete mining of the other, unless a sufficient quantity of timber is used to ward off the fall. This timber later interferes with a satisfactory fall at the time such a breaking of the roof is desired.

The Pillar-Splitting Problem

Fig. 6 is a cut of several pillars which are being pulled back by splitting. A_4 shows the split in the pillar, with the wings *B-B* remaining, C_4 shows a portion of the right wing removed by attacking the pillar at the point D_4. The shaded area E_4 represents the fall which occurs, keeping the miner from the extreme inside portion of the left wing. If this fall is warded off, good sound timber will have to be used freely as shown at *F*.

What more frequently happens is that the split in the pillar is driven as at A_2 and the pillar is attacked at D_2, but all of the coal is not mined. A good sized stump of coal as at G_2 is left behind to support the roof, the quantity of good coal lost depending on the thickness of the seam. All the way back to the entry, some of the coal is left.



Sometimes it is mined as at A_1, leaving a shell of coal on both wings all the way back to the heading. The miner loading the coal from the wings is often apt to leave a larger shell than he supposes, as a result of poor alignment of the split or of the room and this large quantity of coal acts as a fulcrum or pivotal point, preventing a good clean fall of the roof.

Thus the weight which should be on the bottom is thrown onto some nearby pillar, causing it to be unduly strained, and if the number of pillars working is great and the losses of coal occur too frequently within a limited area, a squeeze may result which will cause serious losses of coal.

Loading an Old Slack Pile

By F. W. Whiteside*

The recent Colorado coal strike, which was called Sept. 23, 1913—while unable to tie up all the mines in any of the coal-mining districts—has caused suspension of operations in a sufficient number in Fremont County to curtail the output seriously. But three properties, two of which belong to the Victor-American Fuel Co., are now running.

The Loaded Scoop Nearing Discharge Point and Returning after Being Dumped

In this district are located the Ideal and Concrete Portland Cement plants; two of the power plants of the Arkansas Valley Ry. Light & Power Co., the United Oil Co.'s refinery, and a number of smaller concerns, all of which consume a large quantity of slack coal.

To meet the shortage of production, a contract was let to the firm of Fox and Smith to load coal from some of the old slack storage or better waste piles at Coal Creek and Magnet mines, upon railroad cars for shipment to the plants above enumerated.

The contractors who have undertaken to load this coal, have a somewhat unique plant consisting of a 50-hp. a.c. electric motor, a double drum drag-line hoist and a large

*Chief engineer, Victor-American Fuel Co., Denver, Colo.

scraper or scoop. The operation can best be likened to a main and tail rope mine-haulage system in which the scraper takes the place of the coal trip. The scraper presents an advantage, in that it dumps without being detached from the ropes.

The electric motor and hoist are mounted upon the same floor system, which is provided with lateral skids, enabling it to be moved upon rollers as a unit whenever a change in position becomes necessary.

By changing the location of the tail-rope sheave directly behind the drag scraper, an immediate adjustment in the course of travel of the latter is effected, so that by this means and by a slight altering of the head sheave just in front of it, a wide range of territory can be covered without moving the hoist.

The best day's run loaded twelve 100,000 lb. capacity steel gondolas to their fullest capacity. An average of nine cars in eight hours, including moving and delays, is easily obtained. The operation of loading can be han-

THE SCOOP JUST AFTER DUMPING

dled by two men, although more are required when it becomes necessary to move the hoist.

The power is charged to the contractors at a flat price per month, but as it is less than the cost of a single laborer, it is readily seen that the expense of loading per ton is very light, and the speed of operation reasonably great.

It is quite possible that a much higher capacity could be maintained, but in the case before us the actual demand had to be considered, and the supply regulated accordingly.

From the above it will readily be seen that by this method slack can be loaded both cheaply and effectively; much more so than with a dipper, as the speed of operation of the drag is considerably greater.

By mixing this material with new slack direct from the mines, good results are obtained, excepting in the case of the cement kilns, where it is necessary to use undiluted fresh slack.

Coal Mining Institute of America

An executive meeting of the directors of the Coal Mining Institute of America, was held Jan. 8, at 2 p.m. in the offices of W. E. Fohl, Farmers Bank Building, Pittsburgh, Penn.; Jesse K. Johnston, I. G. Roby, A. P. Cameron, Joseph Knapper, W. Seddon, and C. L. Fay being in attendance, also S. B. Smith by invitation of the president.

Mr. Johnston reported that inquiries made from 50 members, revealed a desire to make the papers and discussion follow lines interesting to the general run of mining men avoiding the more technical subjects. It was suggested that the secretary should urge on operators the advantage of having their fire bosses and foremen present at the semiannual meetings.

MEETING TO BE HELD IN BIRTHPLACE OF INSTITUTE

The summer meeting was arranged to take place at Monongahela, Penn., that being the birthplace of the Institute. The date was left for later determination, but it will be in June and so arranged as to avoid conflict with the Mine Inspectors Institute of the United States, which is held on the second Tuesday in June and this year occurs on the 9th.

A local committee was named to make arrangements at Monongahela, with Alexander McCanch, state mine inspector, chairman.

The other committeemen are Henry Loutitt, the first president and former mine inspector, William Bird, H. T. Booker and W. A. Luce.

It is too early to give the program in detail, but a paper will be read on the Lake Erie and Ohio River Ship Canal. Timbering methods will be discussed by J. M. Armstrong and William Seddon. Possible substitutes for mine posts will also be discussed and correct methods of timbering will be illustrated by stereoptican views. A. P. Cameron will discuss "Accidents Caused by Machine Mining As Against Pick Mining" and a paper is expected on efficiency methods in mining as exemplified in actual practice.

Mine Explosion in Alabama

BY SPECIAL CORRESPONDENCE

A local gas explosion occurred in the Rock Castle mines of the Davis Creek Coal Co., 30 miles southwest of Birmingham, Ala., on Saturday morning, Jan. 10, killing twelve men. Gas had been reported that morning by a fireboss, in three rooms on the seventh right entry.

After the miners went to work, a mine foreman and a brattice man went down in the mine to investigate the presence of the gas. The explosion followed soon after their entrance, killing them and all the others in that entry; the balance of the mine was not affected. The bodies were recovered by 7 p.m. They were all horribly burned and the men had in all probability been killed instantly. Ninety men were in the mine at the time of the explosion.

Engineers Society of Northeastern Pennsylvania

The Seventeenth Annual Dinner of the Engineers Society of Northeastern Pennsylvania will be held at Hotel Jermyn, Scranton, Thursday evening, Feb. 5, at six-thirty o'clock. The cost per plate will be $3.50. As in the past, members will have the privilege of bringing guests, provided one week's notice is given. Tickets for guests may be procured from the Ticket Committee.

Editorials

Looking Ahead

At no time in recent years has the business outlook in coal mining appeared brighter. We are gradually reaching a point in the fuel industries where producers pay more regard to the demands of the markets. It is no longer easy to open a mine by simply building a railroad dump and driving a drift into the seams. Desirable coal lands near good markets are not available in quantity except at a stiff price. It is also true that recent legislation to safeguard miners has shouldered the owner with an expense for equipment and operation that cannot be borne by the small individual.

All this means that the consumer will have to pay more for his coal, but he will not complain when it is made clear to him that the additional cost is utilized to conserve both men and mineral. Coal mining is the one great industry of the nation where there is no margin of profit for lawmakers to lay a tax upon. The cost of improved conditions must be added to the market price of the fuel we burn in our homes and factories.

And there is no sincere regret to be expressed at the passing of the small operator. His methods were the most disturbing influence in the industry. He found it practically impossible to make money himself, and prevented the larger corporations from doing a satisfactory business.

That conditions in the bituminous industry are tending toward greater stability is the belief of all those who are well informed in coal matters. We have in this country practically inexhaustable supplies of natural fuel, but it is likely that the coming revival in general business will find our mines none too big to satisfy the demands that will be made upon them.

Of course, we have all heard it said that we could immediately double our annual output with the mines now operating, but the statement lacks truth. At the present time, it is a fact that most of the days and hours when our collieries are not working, are given over to necessary repairs to machinery, to the placing of timbers, and to cleaning the underground workings generally. It is fallacious to say that because a shaft will produce 1500 tons in 8 hours, the same shaft and mine by working double shifts, can be made to produce 3000 tons for each of the possible 300 working days of the year.

We hazard the suggestion that American coal operators would have difficulty this year in adding 25 per cent. to the coal production of the United States if called upon to do so. And when we consider that in case of a nation-wide improvement in business, the present railroad equipment of the country would be inadequate, it becomes evident that a few outside influences must be reckoned with.

We sincerely hope that transportation facilities and mine capacity will be the only determining factors in 1914, however, it is a stretch of optimism to believe that "wage scales" this spring will be renewed without some trying moments. It is to be hoped, however, that arrangements will be satisfactorily concluded whereby the mines can continue in operation even though new contracts are not signed by Mar. 31, when present agreements expire.

The year 1914 in coal mining can be made a period of record prosperity for operator and miner alike if each will exercise great forbearance in his dealings these next few weeks. Every evil cannot be remedied in a day, and some sore spots still remain in the coal business; however, general conditions in our mines and camps are so far improved beyond what they were a few years ago, that a look backward can leave no doubt concerning the rapid progress that has been made.

Of course, if we manufactured automobiles instead of mining coal, our labor disputes would be at an end, for we would only have to hand out a few millions of profits and strikes would be matters of ancient history. But there! that is idle conjecture, for automobiles are luxuries while coal, like food, is a necessity. According to common parlance, a necessity is something we *ought* to have, but a luxury, such as our motor car, ah! that's different, that's something we *must* have.

Kincaid, Illinois

Our readers will find in the Sociological Department a description of Kincaid, but we think that most will find the principal interest not in the village as such, but in the light the article throws on the attempt of the operator to avoid the fierce competition of the coal market and work his way into the power-selling industry.

There are altogether too many artificial conditions in the life in which we live and some arise from the attempt of some people to get just what they want, regardless of the expense it may take to get it. When the producer and the buyer are one, there is immediately an endeavor to modify the demands of the latter to meet the producer's ability to supply those requirements.

If the miners get the right to shoot coal out of the solid, there are several ways to avoid the loss which results from this provision. They can be made to undermine their coal by hand, by a contract which expressly requires it; they can be supplied and required to use undercutting machines, or the market can be brought to accept slack. Eventually we believe that small coal will be the general demand of the market and the only question remains whether we shall use slack or pulverized coal. But for the present, the operator can only keep the slack for his own use and sell the large coal to the manufacturer or railroad if he would make a profit.

The requirements of low sulphur and ash are largely removed when power is generated at the mine. When he consumes all or the bulk of the coal he mines, the coal operator is enabled to make the boiler equipment suit his coal and thus get better satisfaction from it than it would give in the general market.

So long as the operator uses his large coal to run his plant, so long it will be hard for him to force fine coal on

an unwilling market. When he is using the slack himself, both he and his force of salesmen can with justice urge the installation of slack-burning furnaces. When all the coal is shipped in that form, there will be less pilfering from the cars and it will no longer be true that slack is lower in thermal units than the larger product and has, in many cases, a greater readiness to clinker.

Moreover, many coals which in the market are not meeting with success, we shall find a way to burn when there is a demand for power at the mine. The outward appearance or the analysis or a low clinkering temperature will not suffice to condemn a coal if a method can be found of burning the fuel with efficiency. The more will this be true because the impurity will not have to be hauled a hundred or more miles with the coal with resultant increased cost for pure fuel substance at the point of delivery. Nor will the ash have to be carted several miles into the country or loaded in railroad cars when coal is burned at the colliery power plant.

Fortunately the Christian County coal is of remarkable purity and probably the Peabody operation is in no need of any or all the advantages described, but there are many plants where a central station for power sale would make all the difference between bankruptcy and success.

Certain it is that combinations which follow a product all through its modifications as iron ore to finished steel, or coal to delivered power, conserve our natural resources and our labor even more than those trusts which working as it were horizontally, combine all those who are engaged in promoting a single process in the whole chain development.

These vertical trusts are those which should be fostered for the good of the public for they do not restrain the freedom of business unless the products or some of the products they deliver are sold by them in such large proportion of those from all sources as to restrict competition in them.

The Labor Union

The labor union is a menace to the country but so are the combinations of operators. We sincerely hope that the nation will never tie its hands in dealing with either when the time for action arrives. If either tries to obtain a strangle hold on the public, let there still be a power in the courts to declare that the laws of the game of life are being violated.

We believe that the Sherman bill, if its true meaning be taken without any "light of reason," condemns all labor unions as combinations in restraint of trade and declares the interstate agreement a violation of law. But like Mr. Seager, in his remarks on p. 114, we believe that if workingmen cannot form a union legally, they should receive that power, but the purposes of their association should be strictly limited and accurately defined.

Perhaps the British law of 1875 that what is right for one man is not wrong for an association, would apply without harm to trades unions, but we cannot be satisfied with its applications to combinations of producers and manufacturers. One man can, without wrong, place his prices as high as he pleases, but it does not seem well to permit a combination of men to conspire to raise prices 100 or 1000 per cent. with legislative approval and consent. Try as we will, we find it hard to bind the laborer with the same cords as his employer without making labor unionism completely illegal or placing trusts largely under the protection of the law. This the British law and Mr. Seager do not fail to recognize.

But between making the confession that we cannot restrain trades unionism altogether and permitting it to go utterly wild to the destruction of the country, there are many intermediate stages. We are convinced that the closed shop and the button strike, with or without an agreement, are as clearly infringements on the rights of the workingman as was the old "iron-clad" agreement which operators made employees sign in the earlier days of mining history. We are convinced that sympathy strikes and those which are continued against operators who are willing to concede the wage scale are opposed not only to the Sherman law but to every reasonable moral code.

Stampeding the body politic is tantamount to treason and fortunately it has not been common in this country. We hope it may never be, but we would as soon fail to provide against it by law as blot out Art. 3, Sec. 3 of the United States Constitution against treason, because the practice of such perfidy has become infrequent.

We have a difficult problem in this country. Those whose wrongs most appeal to us abroad are the very persons who, admitted to citizenship or to the country, make the most dangerous people. They may not have sufficient knowledge of our language or customs to be leaders, but they are always ready to follow. Centuries of oppression have given them a readiness to resist and a power of believing anything of those to whom they are opposed. The Finn and the Pole are often far from being grateful for what they receive and are more confident than any others that they are being wronged. Knowing full well the greed with which they would be animated were they in the ascendant, they cannot credit anyone with even a passing interest in their welfare.

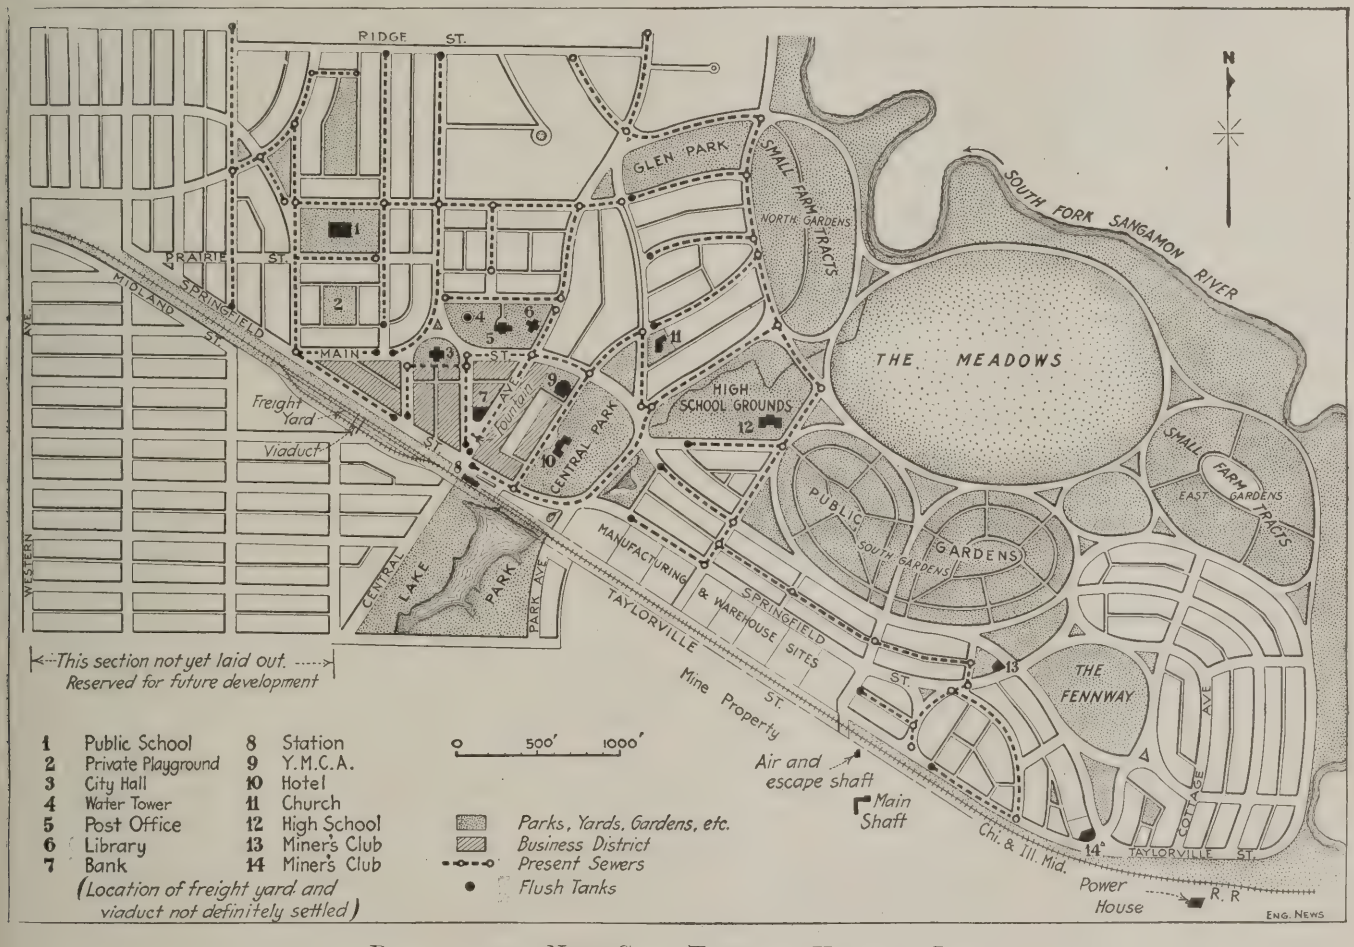
It speaks well for the American heart but not for the American brain that the public of this country is willing always to assume that the foreigner is right whenever his protest takes a riotous aspect. Perhaps the citizens of Routt County, Colorado, and Houghton, Mich., have a right understanding of the difficulties at issue. Like Mrs. Pankhurst, many of the disturbers of the peace thank providence that they live in times of oppression, for they do so dearly like a fight.

Uniformity in Annual Reports of State Mine Inspectors

In compiling the data for our annual statistical number, which appeared last week, considerable trouble was experienced through the lack of a common basis of calculation on the part of the various state mine inspectors. Several states make their coal report for the fiscal year ending June 30. Others report for the year ending Sept. 30, and one state report covers the twelve months ending Oct. 31. And this is not the only point of difference. Several inspectors made their estimates on a basis of gross tons, which basis of calculating output is sure to be highly misleading.

Why can't we all get together on common ground and make an annual report of the coal business in short tons for the regular calendar year ending Dec. 31?

Sociological Department



Peabody's New Coal Town in Illinois

SYNOPSIS—F. S. Peabody and S. Insull are building a model town for coal miners and others, at Kincaid, Ill. The builders planned their town with the help of John Mitchell, formerly president of the United Mine Workers of America.

A new town now under construction in Illinois is of special interest in that it is located in open farming country at some distance from any center of population, and that its design has been unhampered by any considerations or conditions of existing utilities. The distinct and interesting feature of this enterprise is the application of practical town-planning ideas for an average population in a coal-mining district.

The town is being established by F. S. Peabody and Samuel Insull, of Chicago, mainly as a place of residence for the miners of a coal-mining property recently placed in operation near the townsite and for the operatives of a large electric power station. They represent the Peabody Coal Co. and the Central Illinois Public Service Co.

While the purpose of the enterprise is commercial, it is being carried out on modern lines in regard to planning, public utilities, housing and sociological conditions. At the same time care has been taken to avoid mere beautification and to keep the practical purposes and limitations of the project strictly in mind. For this purpose the owners had frequent consultations with John Mitchell, formerly president of the United Mine Workers of America.

PLAN OF THE NEW COAL TOWN OF KINCAID, ILL.

THE TOWNSITE

This new town, which has been named Kincaid, is almost in the center of the state, about 20 miles south of Springfield (or 200 miles south of Chicago) and 100 miles north of St. Louis, Mo. It is on a short railway line running west from Taylorville, where it connects with the Wabash R.R. and Baltimore & Ohio Southwestern R.R. The line crosses the Illinois Central R.R. at Pawnee Junction, and extends to Auburn, where it connects with the Chicago & Alton R.R., a total distance of 26 miles.

This railway, the Chicago & Illinois Midland R.R., is

Note—Reprint from "Engineering News" of Jan. 8.

owned by the same interests which own the mines and the new city, and affords a connection with the four large railway systems noted above. At present, the miners live mainly at Taylorville, 8 miles distant, and go to and from work by trains on the local railway.

The area of the site is about one square mile. It is located on the south fork of the Sangamon River, partly on low-lying and partly on undulating land, the maximum difference in elevation being about 40 ft. The soil is black loam to a depth of 2 ft., underlaid by compact clay, with the first coal measure at about 35 ft. below the surface. The plan for the city includes a business district, two residence districts for buildings of the cheaper and better classes, respectively, and an extensive area of park and garden lands. The bank will be owned by Mr. Peabody. The miners' clubs will be operated under control, in order that the liquor problem may be regulated. The design provides for a present and ultimate population of 3000 and 5000.

Paved Streets and a Sewer System

The width of the main streets in the business district is 80 ft., with a 40-ft. roadway and 20-ft. sidewalks. In the residence districts the width is 60 to 66 ft., with a 24-ft. roadway and 18- to 21-ft. parking, the latter including 5-ft. sidewalks 1 ft. back from the property line. The sidewalks and parking have a slope of 6 in. in 20 ft. The paving for the business district will be of brick on a concrete base, while in the residence districts it will be macadam. The alleys are 18 ft. wide.

The sources of water-supply are now being investigated by the engineers. It is planned to put meters on all the services, in order to control the proper use of the water while providing an ample supply.

The sewerage system includes separate storm and sanitary-sewer systems in the business district, and a sanitary system in the residence district. Flush tanks are provided at all the dead ends. The manholes and flush-tanks are of concrete. Sewage purification is essential, the effluent to be discharged into the river, and as there is very little water (sometimes none) in dry seasons, all chance of nuisance must be provided against. Complete purification will be adopted.

All the sanitary sewers are of vitrified pipe, 8 to 15 in. diameter. The sewers are laid in the middle of the streets, with the water mains about 10 ft. from them. An exception to this is at the east end, where the slope of the ground makes it necessary to put the sewers in the alley. Electricity for street and interior lighting will be furnished from the neighboring power plant. This also will supply power for domestic use.

A Third of the Land for Public Purposes

A special feature of the design is the large amount of land reserved for park purposes, this representing 25 to 30 per cent. of the total area. A large public park, called "The Meadows," is laid out along the river and two sections of public gardens in the bottom lands have been reserved for the use of the miners. These are laid out in lots, to be rented by householders, and used for growing vegetables, etc. These garden lots are approximately 100x 100 ft. As the bottom lands are subject to overflow, a dike or levee is being built to protect the lower part of the residence district from flood waters. Rows of trees and shrubs will be planted along the streets.

There will be 10 to 12 miles of streets and water mains, and all streets will be provided with sewers. At present, work is in progress on 7 miles of sewers and an equal length of street grading. No contracts for street paving have been let, but the work of building 200,000 sq.ft. of concrete sidewalk has been commenced by a contractor.

The size of the lots ranges from 30x125 ft. for the miners' houses to 50x125 ft. (or more) in the better residence section. The company will have designs made for dwellings of different styles and costs, and purchasers of lots will be allowed a selection from these. The plans will be drawn to provide for modern conditions of good housing, and sanitation, and all buildings will be erected under the supervision of the company's architect. The company will aid in the erection of the city hall, school, high school, postoffice, public library, hotel, and Y. M. C. A. building. A temporary four-room school has been erected already, for the use of the children of farmers in the vicinity. The railway will build a new station. The first stores and prominent buildings of the business district will be designed and built by the company. A number of residences, three store and office buildings and the railway station are under construction, and occupation of the new city will commence within a short time.

The municipal engineers are Alvord & Burdick, of Chicago, who have designed the street, water and sewerage systems and have supervision of the construction. The architect is George W. Maher, and the landscape architect is O. C. Simonds, both of Chicago. All construction work is being done by the Pawnee Construction Co., whose engineer is W. H. Leland. About $100,000 have been spent this year on municipal improvements.

Planning Methods

The office methods of the engineers in preparing the design of the city were as follows: in the first place, a topographical map was made of the entire area, with 1-ft. contours, to a scale of 1 in. to 100 ft. The streets were then located to fit the topography, and profiles and cross-sections drawn. Then the grades were adopted, together with the widths and forms of cross-section of the streets. Next the sewers were laid out, and sewer profiles drawn. Profiles were then made for the grading, these showing the profiles for the center line and both property lines, with cross-sections for each 100-ft. station. A record map or plat was then made, showing all dimensions. Each lot can be located from $\frac{1}{16}$ corners, which are marked with concrete posts 8 in. square and 4 ft. long, each having a $\frac{3}{4}$-in. brass plug or bolt in the top, with a crosscut in the center of the head.

Mines and Power Plant under Same Control

Reference has been made to the large power station built recently in the vicinity. This is about a $\frac{1}{2}$ mile from the southeastern corner of the town, being located near the mines and thus assured of a cheap and ready supply of coal for power development. It is designed for an ultimate capacity of 10,000 kw., and will distribute current within a radius of 25 or 30 miles. The plant was designed by Sargent & Lundy, consulting engineers, of Chicago. It is operated by the Central Illinois Public Service Co., which owns a series of power plants and transmission lines.

Discussion By Readers

Results in Discussion

Letter No. 1—Referring to the question of the adoption of some definite plan or policy that would determine conclusively the safest and most successful measures to employ, as suggested in the inquiry, COAL AGE, Nov. 22, p. 786, it is clearly apparent that this is a difficult matter.

The roads to success are many. To bring the discussion of a question to a successful and practical climax is not always an easy matter. Many of the letters written on the subjects discussed in COAL AGE come from men prominent in the mining industry in this country, men of acknowledged ability. Their letters are, in most instances, expressions of actual experience.

It goes without saying that when a practical man has found that a certain method brings good results, he is bound to advocate its adoption, under conditions that appear to be similar to his own. These conditions may or may not be fully explained and understood by all and to this fact may be attributed the success or failure of the plan when adopted by others.

We are often prejudiced in favor of methods with which we have become familiar. To illustrate this point, permit me to give an incident in my own experience. While engaged in my first work in surveying, I was taught to use a tape 300 ft. in length and employ the method of vertical angles for reducing the measurement on the pitch to horizontal distance.

Being employed, later, in another section, I was forced to use a tape only 50 ft. in length. The practice in that locality was to take all measurements on the horizontal. I did not hesitate to condemn this method, but found, after all, that just as accurate results were obtained by the horizontal measurement.

Argument rarely convinces men of prejudiced ideas. The old Scotch adage, "A man convinced against his will is of the same opinion still," aptly applies to a large number of mining men. Every practical mining man, however, will freely admit that the publication of letters relating the experience of others, is of infinite value to the mining industry. By this means, ideas are brought out that would never find expression in print but for this method of discussion. Without a doubt, many of the ideas expressed in the letters are acted upon by others and their merits proved or disproved as the conditions permit. There is always a wrong and a right way to mine coal, but there are many varieties of the right way.

G. M. SHOEMAKER.

Pennington Gap, Va.

Letter No. 2—Mine Superintendent, COAL AGE, Oct. 11, p. 555, and Charter Subscriber, Nov. 22, p. 786, seem to think that COAL AGE or someone should determine the superiority of the proposed methods of safety in mining; and that it should be possible to point out certain definite conclusions in regard to methods that seem to recommend themselves as being superior to all others in handling the dangerous problems that confront mining men today.

I have wondered if the above mentioned parties fully realize the magnitude of the requests they make. To ask for the best plans and methods to be adopted and definite conclusions relative to unsettled questions is one thing; to produce such plans, methods and definite conclusions, under all conditions in mining, is quite another thing. Almost everyone will acknowledge that it is a difficult proposition to lay down plans and methods of safety in mining that will be universal in their application. We all realize that local conditions have much to do in determining the safest methods to pursue. What might be done with a reasonable degree of safety in one mine would, perhaps, be dangerous practice in another mine, although, perhaps, the conditions are almost identical in the two mines.

We may ask: What are the elements that give rise to dangerous conditions in coal mines today; and the answer will be, in most cases, "gas and dust." However, the danger does not consist so much in the presence of gas and dust as in the carelessness, lack of knowledge and discipline of mine officials and the unsafe methods adopted by them, in dealing with these recognized dangers.

The discussions in COAL AGE have resulted in bringing forward many essential points in respect to safety in coal mining, by men of broad experience. It may be true that each writer has written, more or less, from the standpoint of his own experience and with respect to conditions with which he is most familiar. Nevertheless, any reader who has given careful attention to the arguments advanced has surely reached conclusions that will enable him to adopt better and safer methods of mining. It is true that opinions may differ even among men of like experience, but the preponderance of opinion will generally control and point the way to safety.

As a concrete example of this, out of the 19 letters submitted in the discussion of Mixed Lights in Mining, there were but six in favor of the use of mixed lights in mines generating gas, as compared with 13 that were unalterably opposed to the practice. It is reasonable, therefore, to conclude from this discussion that: *In respect to safety, all mines generating gas, in a single section only, should be operated exclusively with an approved type of safety lamp.*

Again, in the discussion on the Effect of the Safety Lamp on the Eyesight, the statement that the continued use of the safety lamp affected the eyesight of the miner and reduced his producing power was not proven to satisfaction, since it was not shown to affect all miners alike. Attention was drawn to this in a brief editorial note, COAL AGE, Oct. 18, p. 585. In the same discussion, it was not shown fully that the use of the safety lamp in mining reduced the producing power of the miner, as was claimed by some. The one argument advanced against the use of the safety lamp, to which all agreed, was its inconvenience in handling.

The eight letters, thus far submitted, discussing the question of Starting a Fan after an Explosion, in a mine, failed to deal specifically with this subject and to make it clear whether or not it is advisable as a means of safety to life and property, to start a fan that has been temporarily disabled by an explosion, before the work of rescue and exploration is undertaken. The failure, in this case, to arrive at a definite conclusion, is probably due to the fact that local conditions have much to do with determining the answer to this question. It must be admitted, however, that the opinion was pretty generally expressed that the condition of the mine workings should be ascertained, in respect to the existence of fires that may have been started in different parts of the mine by the flame of the explosion; and that this knowledge should be obtained by the use of helmets, or other breathing apparatus that would enable rescuers and explorers to enter the mine workings before again starting the fan. A valuable suggestion was also made in several letters to the effect that the work of exploring the mine and restoring the ventilation therein should be performed in sections, which would greatly simplify the task and reduce to a minimum the danger of a second explosion.

The weight of sentiment expressed in the 10 letters submitted in the discussion of Collapsible Stoppings is unquestionably in favor of building substantial stoppings on all main entries and air courses. There have been, thus far, but six letters submitted in the discussion of the Education and Training of Mining Men; but the sentiment expressed in these letters is in accord with that of the editorial, COAL AGE, Oct. 18, p. 585, which makes such education and training *"the recognized cornerstone of all effort for improving conditions in coal mining."* The unanimous verdict in this discussion was that safety in mining will be achieved only in that direction. Since local conditions must largely control and determine the means and methods to be adopted, the greatest responsibility devolves upon the mine foreman, who must use his best judgment in the selection of plans and methods of working. It is this fact that makes it absolutely essential that the mine foreman, more than anyone else, have this education and training.

JOHN ROSE,
Dayton, Tenn. District Mine Inspector.

Collapsible Stoppings

Letter No. 11—I read with much interest the several letters that discussed the question of the practical use of collapsible stoppings to stay an explosive wave in its course through the mine entries by allowing an expansion at the point of origin. I feel that one point, at least, has not been brought out in that discussion and believe that attention should be drawn to that particular point, which applies with equal importance to air bridges or overcasts, as to entry stoppings.

Personally, I believe that all entry stoppings should be built in such a manner as to permit of their being hermetically sealed to prevent any leakage of air, and strong enough to withstand any ordinary shock due to blasting or concussion of the air due to a fall of roof. On the other hand, I do not think entry stoppings should be constructed so strong (if it were possible) as to resist the shattering effects of a violent gas or dust explosion.

Assuming that a small local explosion of gas or dust occurs at some point midway in the mine, the argument is pertinent that the destruction thereby of one or more entry stoppings will not only allow a further expansion of the air and gases of the explosion; but what is of more importance, perhaps, will short-circuit the air current at that point; and, as a result, the gases of the explosion will pass out of the mine by the main return instead of being carried inby and made to traverse the mine workings where many would be suffocated by the afterdamp of the explosion.

The readers of COAL AGE will undoubtedly recall cases in their own experience where the circulation of the air having been destroyed by the displacement or destruction of an overcast, brattice or stopping, the men inby from that point who remained at their places were rescued later when the circulation in the main entries was established. It will be remembered that, in some cases, men who attempted to escape by the main entries were quickly overcome by the afterdamp, at points outby from the explosion.

Such instances were very notable at the Bellevue disaster, Alberta, Canada, Dec., 1910. The stoppings in that mine, which were built of 2x12-in. plank, readily yielded to the pressure of the explosion, thus permitting a rapid expansion of the air and gases, with the result that the concussion was barely perceptible in the inner workings of the mine. In this case, 21 men lost their lives in trying to escape by the main entry, as the afterdamp of the explosion filled both the intake and return airways outby from the point of explosion. The eight men who had retreated to the face of the entry were rescued 10 hr. later.

The mistake of attempting to escape by the main entries, after an explosion in the mine, has been demonstrated repeatedly by the finding of dead bodies scattered along the main entry, at long distances from the working face. In some cases, it has been possible to observe that the victims of the disaster had discovered their mistake too late and attempted to retreat inby, as shown by the footprints in the soft floor.

J. W. POWELL, Sup't.,
Windham, Mont. Cottonwood Coal Co.

Letter No. 12—All stoppings are "collapsible" when considered in reference to the force of an explosion. The Roslyn, Comax or Cumberland, B. C., the Black Diamond or Western Washington, and, in fact, all the coalfields of the Northwest build their stoppings in practically the same manner.

The general method of construction is as follows: Two props are stood, one on each side of the crosscut, close to the rib, and a third prop in the center, in line with the other two. A double thickness of 1x12-in. rough boards is then nailed to the props in a horizontal position to avoid fitting, which would be necessary if one thickness was laid diagonally. The boards, however, are made to break joints; and, to further prevent the leakage of air, the cracks between the boards and the ribs and roof of the crosscuts are caulked with strips of brattice cloth secured by cleats nailed to the boards.

A heavy blownout shot or a few blows of a sledge will knock down these stoppings so that there can be no question but that they are collapsible. In some mines, the room stoppings are made even more flimsy. In many cases but one board is nailed to the top and another to

the bottom of the props, and brattice cloth stretched across them, with long cleats nailed on the two sides close to the ribs of the breakthrough to hold the edges of the cloth.

But few concrete stoppings are built in these fields, and they are seldom more than 4 to 6 in. thick. The mines of the Northwest, however, as a rule, are carefully managed and thoroughly inspected, the British Columbia mining law being particularly strict in this regard; yet explosions have occurred in them. Comax mine No. 6, Cumberland, B. C.; Lawson mine, Black Diamond, Wash.; and No. 4 shaft, Roslyn, Wash., each have had their explosions, and while the stoppings were all blown out, it would be difficult indeed to say that this fact had any appreciable effect on the force of the explosion.

When an explosion traverses a long entry, having rooms turned off every 50 or 60 ft., making available acres and acres of open space for the expansion of the gases of the explosion, and this fact does not arrest its progress, it does not appear reasonable to suppose that the limited area of the airway made available by the blowing down of the stoppings in the entries would have the desired effect even at the initial point of the explosion. The crosscuts between two airways are generally farther apart than the mouths of the rooms turned off the airways; and, even assuming that the entry stoppings were blown out, the entry space thus made available for the expansion of the gases would not be one-hundredth of the space already open to their expansion in the rooms.

The building of so called "collapsible stoppings" in these fields is the general practice; but this is done for reasons of economy and not for the purpose of limiting the force of an explosion, should one occur.

RALPH W. MAYER.

Roslyn, Wash.

[The above rather sweeping description of the method of building stoppings in mines in the Northwest, submitted to the chief inspector of mines, B. C., Canada, brought the following comment in response.—Ed.]

Your correspondent's description of the methods of erecting stoppings in the mines in this region, I believe, must carry him back many years. The system as described by him is still used in crosscuts between stalls or rooms, in a panel district or when building a temporary stopping to carry forward the air in a pair of headings, pending the erection of a more permanent stopping.

There are quite a few mines in British Columbia equipped with modern high-speed fans, delivering from 120,000 to 225,000 cu.ft. of air per minute, against water gages varying from 4 to 5½ in. It would seem practically impossible to obtain these results in a mine where the main stoppings were built in the manner described. You may recall having observed, at the time of your visit to the Crow's Nest Pass Coal Co.'s mines, in 1904, that the type of entry stoppings, in use in those mines was cedar logs flattened to not less than a 12-in. face, the log being set in concrete and faced with the same.

The general principle adopted by the Crow's Nest Pass Coal Co. today is the four-entry system, consisting of a double pair of entries separated by a pillar of coal 150 ft. thick. This central pillar is crosscut only every 100 yd. Eventually, one pair of entries is made the intake and the other pair the return for the mine, which plan greatly reduces the number of stoppings necessary to control the ventilation.

The statement of correspondent that concrete is not used much in building stoppings in the Northwest is wide of the mark. To my knowledge, one mine alone, on Vancouver Island, used in one year, no less than 10,000 sacks of cement in erecting stoppings and overcasts These stoppings varied in thickness according to the area of the crosscut, from 12 to 24 in. In some mines, timber blocks are laid in fine refuse with cement facings; in others, the crosscuts are gobbed tight with refuse, in the usual manner; and the walls thus laid at either end of the crosscut are faced with concrete. My remarks are intended to refer only to the mines in British Columbia.

THOMAS GRAHAM,
Chief Inspector of Mines.

Victoria, B. C., Canada.

Starting a Fan after Explosion

Letter No. 9—Referring to the interesting discussion, a short time ago, in Coal Age, on the question of starting a fan that is assumed to have been disabled by an explosion in the mine, I thought it would be of interest to call attention to one or two incidents where lives were saved by the immediate or continuous operation of the fan.

Because of the varying conditions not only in different coalfields, but in different mines in the same field and often in different seams in the same mine, this is a difficult question to answer directly. To say that the fan, after being repaired, should be started at once in order to restore the circulation in the mine, would not be safe, in all cases. While some mines are free from gas and dust, others are troubled with one or both of these dangers. I have found this true in the Cahaba coalfield, in this state.

I have noticed that some writers treat this subject from a purely theoretical standpoint and others from a wholly practical basis. Most men will agree, however, that the practical knowledge of mining affords the stronger hope of rescue for the unfortunate survivors in the mine. The letters thus far submitted have proved of much value, in showing the different conditions that may exist and in the caution they suggest. In discussing the question, some assume certain conditions that do not exist in all mines, as, for example, that each crossheading has its own separate air split; and conclude that an explosion occurring in one of these headings would not affect the other parts of the mine or would not at least, result in a general explosion.

The Acton Mine Explosion

The explosion that occurred at Acton, Ala., Mine No. 2, Nov. 18, illustrates the value of maintaining the circulation in the mine entries, immediately following an explosion, at least under many conditions common in mining. The Acton mine was opened by a slope pitching about 24 deg. and cross-entries had been driven to the right and left of the slope, as far as the ninth level. The mine was ventilated on the split system. The fan was but slightly jarred by the explosion and was soon running again, as usual.

Two rescue parties were organized; and, while one was engaged in restoring the ventilation, the other party was searching the cross-entries and succeeded in bringing

out five men who were found alive. Of the 29 men in the mine at the time of the explosion, the remaining 24 were killed, 16 of these being killed by afterdamp and 8 by the immediate force of the explosion, which was of great violence. The explosion started on the eighth left heading and was caused by a blownout shot. Little gas had been found in the mine, which was considered one of the safest in that district.

This explosion traveled out the slope and destroyed every overcast and stopping along its path. In this case, the split system of ventilation did not save the mine from a general explosion, as some have claimed it would. However, it may be stated that the natural conditions in this mine favored the plan of restoring the ventilation at once, as the coal was hard and would not take fire easily.

Explosion in Another Mine

Another explosion occurred some two years ago, in a mine in the same county, in the Wadsworth seam, which was about 3 ft. thick. This mine also was ventilated on the split system. Undercasts were used instead of overcasts and these were driven through the solid rock, so that the circulation in the splits was not affected by the destruction of the air crossing. The mine was dry and dusty, and previous to the explosion I had watered every heading in the mine. The seam pitched 30 deg. Here, also, the cross-headings were driven off the main slope and rooms turned to the rise of these headings were worked on the chute system.

The immediate cause of this explosion, which started at the face of the fourth heading, was the ignition of a keg of powder that the entryman had left there when charging the holes. In this case also, the flames came out of the heading and traveled up the slope. Fortunately, most of the men were below this heading, and no one was on the slope. In a short time, about 2 min., however, these men began to feel the effects of the afterdamp which would have proved fatal but for the sudden restoration of the air current, due to the action of the fan, which had not stopped. Had the fan stopped, all would have been lost in 10 minutes' time. In my opinion, what saved these men was the fact that all the slope stoppings were built of heavy concrete and brick, and the undercasts, as before stated, were driven through the solid strata.

If this condition existed in other mines, it would often result in the saving of many lives that would otherwise be lost. It is important, also, that the fan be set so that it will not be damaged by the explosion.

Robert Gibson.

Helena, Ala.

Study Course in Coal Mining

By J. T. Beard

The Coal Age Pocket Book

Estimation of Air Columns in Practice—In the ventilation of shaft or slope mines or rise and dip workings in inclined seams, the weight of each respective downcast and upcast column is sometimes calculated separately, by multiplying the weight of 1 cu.ft. of air, at a barometric pressure B and a temperature t equal to the average temperature of the column, by the height or depth D of the same column, as expressed by the formula

$$w = D\frac{1.3273\,B}{460 + t}$$

All air columns are of unit cross-section (1 sq.ft.) and the calculated weight of the column, therefore, gives the corresponding pressure in pounds per square foot.

Positive and Negative Air Columns—An air column that acts to assist the circulation in the mine or airway is called a "positive" column; while one that acts to oppose the circulation is turned a "negative" column. In fan ventilation, a negative air column may exist in the downcast shaft by reason of its temperature being greater than that of the upcast, which frequently happens in the summer season.

Conditions—The height or depth D of air column, in any particular case, can only be determined by carefully consider-

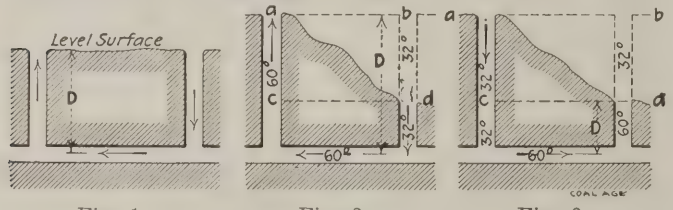


Fig. 1 Fig. 2 Fig. 3

Fig. 1. Level Surface, and Level Seam. Fig. 2. Upcast Deeper than Downcast. Fig. 3. Downcast Deeper than Upcast.

ing the conditions. It is important to remember that, with few exceptions, the temperature of a downcast-shaft column will closely approximate that of the outer air with which this shaft is constantly filled; while the temperature of the upcast column is practically determined by that of the mine or, in furnace ventilation, by the furnace.

When two shafts, upcast and downcast (Fig. 1), are sunk from a level surface or, in other words, have the same surface elevation it is evident that this level marks the upper limit of both columns.

When, however, the two shafts are sunk on a hillside and have different surface elevations, two cases may arise, as illustrated in Figs. 2 and 3, where, for sake of clearness, the outside temperature is assumed as 32 deg. F. and that of the mine as 60 deg. F.

The Coal Age Pocket Book

The cases are as follows:

1. When the shaft having the higher surface elevation is made the upcast, as is usually done, that elevation marks the upper limit of both shaft columns; because the downcast shaft has practically the same temperature as the outer air.
2. When the shaft having the lower surface elevation is made the upcast this elevation marks the upper limit of both shaft columns; because the air in the other (downcast) shaft above this level is balanced by the corresponding column of outside air.

These two conditions, therefore, are simply expressed by the statement that, in either case, the upper limit of both shaft columns is the surface level of the upcast shaft.

In the same manner it can be shown that the lower limit of both shaft columns is the bottom of the downcast shaft when the seam has a general inclination. Hence, the length (D) of both shaft columns is measured, in any case, from the top of the upcast to the bottom of the downcast shaft. This rule does not apply to slopes.

Ventilating Pressure and Shaft Columns—Since the weight of an air column, in pounds, expresses the corresponding pressure, in pounds per square foot; and since ventilating pressure (lb. per sq.ft.) is the difference of pressure between the intake and return; the ventilating pressure, in any given case, is found by subtracting the weight of the upcast-shaft column from that of the downcast column; thus,

Downcast-shaft column, $w_d = \frac{1.3273\,B}{460 + t}D$

Upcast-shaft column, $w_u = \frac{1.3273\,B}{460 + T}D$

$$p = 1.3273\,B\left(\frac{1}{460 + t} - \frac{1}{460 + T}\right)D$$

which can be written

$$p = \frac{1.3273\,B\,(T - t)\,D}{(460 + T)(460 + t)}$$

Calculation of Air Column—The air column corresponding to the above unit ventilating pressure can be expressed in terms of either the downcast or upcast air. The air in the downcast being heavier than that in the upcast, gives a shorter air column for the same pressure.

To find the air column (h_d) in terms of the **downcast air,** divide the above expression for unit ventilating pressure by the weight (w) of 1 cu.ft. of downcast air (temp. = t), which gives

$$h_d = \frac{p}{w} = \frac{(T - t)\,D}{460 + T}$$

To find the corresponding air column in terms of the **upcast air,** divide the same expression for unit ventilating pressure by the weight of 1 cu.ft. of upcast air (temp. = T), which gives

$$h_u = \frac{p}{w} = \frac{(T - t)\,D}{460 + t}$$

Inquiries of General Interest

Organic Sulphur in Coal

I have a question that relates to the analytical chemistry of coal; and, while I know that it is not a simple determination and one that is not often called for, I would like to ask for such information as some of the readers of COAL AGE may be able to give from their experience or knowledge of the subject. I refer to the determination of the organic sulphur that may be contained in coal.

J. V. FREEMAN, Chief Chemist,
Central Laboratory.

Joliet, Ill.

The most common occurrence of sulphur in coal is in the form of pyrites. This occurs either as nodular masses scattered in the coal, or as thin partings interlaminated with the coal, or as finely divided particles disseminated in the mass. What is known as "organic sulphur" is that form in which the sulphur in the coal is combined with carbon or carbon and hydrogen.

In reference to the determination of the organic sulphur in coal, if any of our readers know of a practical method that will separate and determine the sulphur associated in this form, we shall be glad to publish the same.

In this connection, we would draw attention to the editorial that appeared recently in COAL AGE, Aug. 23, 1913, p. 273, relating to the presence of sulphur in the original ingredients that entered into the composition of the coal, and certain erroneous speculations in reference thereto. Also, the short article entitled, Why Sulphur is Found in Coal, Jan. 4, 1913, p. 15.

Rope Lubrication

Can COAL AGE readers give the records or results of scientific investigation or those obtained practically by a reliable party or company, relative to the lubrication of both hoisting and haulage ropes, under wet and dry conditions, in mining practice? This is a question of the greatest practical importance in coal-mining economy and one that deserves attention. What is the best dope and its method of application, and what results have been obtained by its use, in the prolongation of the life of the rope?

A. H. POLLINS, Supt.,
H. C. Frick Coke Co.

Southwest, Penn.

Steel-wire hoisting ropes should be treated periodically with boiled oil (linseed), which is commonly applied by allowing the hoisting rope to run slowly through a wad or bundle of waste on which the oil is poured in quantity sufficient for the thorough lubrication of the rope. This process is repeated at regular intervals, from time to time, as often as the conditions may require. The frequency of the lubrication can only be determined by closely observing the condition of the rope.

In wet shafts, especially where the water has a corrosive action, some standard preparation of crude petroleum and graphite can be used to advantage. Many lubricating firms furnish a good weather-proof graphite grease that gives excellent results.

Haulage ropes require for their protection a dope of greater substance, as, for example, a mixture of pine tar with, say one-tenth raw oil. This mixture is boiled together at a low heat and applied warm. Care is required not to burn the tar, which would destroy its protective quality. It is also important to ascertain that the tar contains no acid; or, if it does, to neutralize it by the addition of slaked lime to the tar. It is recommended that a peck of lime should be used to one barrel of tar, for this purpose. We should be glad to receive figures showing the effect of lubrication to prolong the life of ropes used in hoisting and haulage, in mining practice.

The Mining Expert

I have noticed, in reading various articles, that some writers style themselves "Coal Expert." As I have not a clear understanding of the full meaning that attaches to this title, I would like to ask what education, experience or capability qualifies one for such characterization.

I. S. C.

Indianapolis, Ind.

The term "expert" has been applied by courts to special witnesses supposed to be capable of giving valuable testimony in relation to the technical or industrial details of questions before the court. The person thus designated is assumed to have a knowledge and experience that fits him to speak with authority on the questions concerning which he is called.

Among reputable engineers, the term "expert" has largely fallen into disrepute, owing to its misuse by men of little or no engineering knowledge or experience; but who assume to have a more or less intimate acquaintance with the conditions involved and to be competent judges of matters in question. The self-styled expert generally has no other stock in trade than the title he appends to his name.

Nothwithstanding the stigma that is thus associated with the term, the true mining expert has a standing that gives weight to his conclusions both in court and in consulting engineering practice. This, of course, is dependent on and determined by his reputation as an engineer. All engineers are not experts, just as all so called experts are not engineers, or even good practical men of sufficient experience to warrant the use of the term.

The essential qualities involved in the rightful use of the word or title, are a thorough and complete technical knowledge, the practical application of which has been taught by a long and varied experience in the field, mine, shop, or laboratory; and, even this dual qualification must be cemented by a sound judgment that commands respect and confidence.

Examination Questions

Miscellaneous Questions

(*Selected Questions*)

Ques.—What is the pressure per square inch in a boiler when the entire length of the lever is 32 in.; the distance between the fulcrum and valve stem being 4 in. and the diameter of the valve 2½ in., if a weight of 30⅝ lb. is hung at the end of the lever?

Ans.—The question is assumed to refer to the lever of a safety valve of a boiler, although this is not stated; neither are the weight of the lever, valve and valve stem and the center gravity of the same mentioned; though they are important for the correct solution of the question. However, neglecting the weight of the lever, valve and valve stem, the solution is as follows: According to the principle of moments, the moment of the weight at the end of the lever is equal to the moment of the entire pressure exerted on the valve through the valve stem. Calling this total pressure P, we have

$$P \times 4 = 30\tfrac{5}{8} \times 32 = 980$$

$$P = 980 \div 4 = 245 \text{ } lb.$$

The sectional area of a 2½-in. valve is $0.7854 \times 2.5^2 = 4.9$ sq.in. The unit pressure on the valve is then

$$p = 245 \div 4.9 = 50 \text{ } lb. \text{ } per \text{ } sq.in.$$

Ques.—What thickness of pillar would you leave around the bottom of a shaft 450 ft. deep, the coal being 7 ft. thick and underlaid with 4 ft. of fireclay; above the coal is 10 ft. of soapstone, the balance of the cover being shale, sandstone, clay and soil?

Ans.—Owing to the fireclay floor and the soft soapstone roof of this seam, the safest rule to adopt is that known as Hughes rule for the least diameter of circular pillar or side of a square pillar. This rule allows 1 yd. in pillar thickness for each yard of depth, which makes the minimum diameter of a circular pillar or the minimum side of a square pillar, 450 ft.

Ques.—The indicated horsepower of a pumping engine, raising 1000 gal. of water per min. 500 ft., in a vertical shaft, is 200 hp.; what is the efficiency of the pump?

Ans.—Since no data are given for calculating the friction of the pipe line, in this case, it is only possible to estimate the efficiency of the system, including both the pump and the pipe-line resistances. Estimating the weight of the water as 12 gal. per 100 lb., the total weight of water pumped per minute is $1000 \times 100 \div 12 = 8333+$ lb. The foot-pounds of effective work performed is then $8333 \times 500 = 4{,}166{,}666+$ ft.-lb. per min. The indicated work is $200 \times 33{,}000 = 6{,}600{,}000$ ft.-lb. per min. The efficiency of the system is then

$$\frac{4{,}166{,}666 \times 100}{6{,}600{,}000} = 63.13 \text{ } per \text{ } cent.$$

Ques.—What percentage of marsh gas in the air makes itself apparent in the safety lamp?

Ans.—The answer to this question depends wholly on the kind of lamp used, the oil burned, the ability of the observer to detect the flame cap and the presence or absence of other gases in the mine air. While the presence of fine coal dust floating in the air or a small percentage of carbon monoxide, assists the formation of the flame cap and makes it visible for a less percentage of marsh gas, the presence of carbon dioxide or a depletion of the oxygen of the air retards the formation of the flame cap. Assuming, however, a pure air and using an unbonneted Davy lamp burning a good quality of sperm, lard, or cottonseed oil, a good fireboss can usually detect about 2 per cent. of marsh gas on the flame of his lamp.

Ques.—Find the breaking strain of a ⅞-in. six-strand, 19-wire, crucible-steel hoisting rope; also the safe working load of this rope.

Ans.—The breaking strain of a 1-in. crucible-steel, six-strand, 19-wire hoisting rope being 39 tons, and the strength of the rope being proportional to the square of the diameter, the breaking strain of a ⅞-in. rope of the same kind is

$$L = 39 \text{ } d^2 = 39 \text{ } (\tfrac{7}{8})^2 = 29.86, \text{ } say \text{ } 30 \text{ } tons.$$

In ordinary hoisting practice, for moderately deep shafts, it is customary to use a factor of safety of 5, which makes the safe working load, in this case, $30 \div 5 = 6$ tons.

Ques.—If 20,000 cu.ft. of air is circulated in a mine, under a 1-in. water gage, what water gage will be required to circulate 60,000 cu.ft. per min. in the same mine under the same conditions?

Ans.—For the same conditions in the airway, the pressure or water gage varies as the square of the quantity of air in circulation. In other words, the water-gage ratio is equal to the square of the quantity ratio, which gives, in this case,

$$\frac{x}{1} = \left(\frac{60{,}000}{20{,}000}\right)^2 = 3^2 = 9$$

$$x = 1 \times 9 = 9 \text{ } in.$$

Ques.—If it is desired to double the quantity of air in a mine or airway, how much must the ventilating pressure be increased?

Ans.—For the same mine or airway, the ventilating pressure varies as the square of the quantity. Then, to double the quantity, the ventilating pressure must be increased $2^2 = 4$ times.

Ques.—If a 40-hp. fan gives 120,000 cu.ft. of air per minute, what quantity of air will a fan of 32 hp. give?

Ans.—For the same conditions in the airway and assuming the efficiency of the fan is the same in each case, the quantity of air in circulation varies with the cube root of the power; or, in other words, the quantity ratio is equal to the cube root of the power ratio. Hence, calling the required quantity x,

$$\frac{x}{120{,}000} = \sqrt[3]{\frac{32}{40}} = \sqrt[3]{\frac{4}{5}} = \sqrt[3]{0.8} = 0.9283$$

$$x = 120{,}000 \times 0.9283 = 111{,}400 \text{ } cu.ft. \text{ } per \text{ } min.$$

Coal and Coke News

Washington, D. C.

A final decision in the important case of the Wisconsin Coal Co. vs. The Pere Marquette R.R. Co., and in several other cases grouped together under the same heading, has been handed down by the Interstate Commerce Commission, and is now just made public.

In this case it was contended by the complainants that they were entitled to free reconsignment of coal at Milwaukee, and asked reparation on account of damage suffered as the result of alleged unjustifiable holding of cars at Ludington, including reconsignment and demurrage charges paid on cars detained, as well as damages. The complaint also embraced a charge of discrimination and alleged that the new tariff effective last February was unreasonable. The commission now holds that the complainants were not entitled to free reconsignment at Milwaukee, but were entitled to such reconsignment at a charge of $2 per car. It is held that the detention of cars at Ludington was unjustifiable, and that demurrage charges were improperly assessed and must be refunded. With respect to cars which arrived at Ludington before the receipt of passing notice and proper time for giving disposition orders, the charges were improperly assessed and should be refunded.

Reconsignment Involving Extra Service Must Be Paid For

There is no evidence upon which to measure damage to cars upon which the notice was insufficient. Generally speaking, it is held that the commission has power in its discretion to require the establishment of reconsignment and diversion on the basis of the through rate from the point of origin to new destination with a fair charge for extra sevice. Further, it is held that a carrier may, as a matter of convenience when its terminal tracks are congested, hold cars at some point short of destination, provided that such a course involves no disadvantage to the public. There are several other interesting points in the case that cannot be briefly treated.

The case in question grew out of a controversy concerning the service of reconsignment to be afforded bituminous coal shipped by the complainants to Milwaukee and diverted to destinations beyond. The complainants were coal brokers at Milwaukee. They had no storage facilities. Their practice is to ship coal from the mines in Ohio, Pennsylvania, and West Virginia to Milwaukee under what is known as a "blind billing." The destination given is, for example, "Milwaukee, or beyond," or "Elm Grove," the latter being a station a short distance outside of Milwaukee on the line of the Chicago, Milwaukee & St. Paul.

Reconsignment Is Due to Carriers' Own Default

Some of this coal is ordered and sold by the complainants under contract. The larger portion of it, however, is "free coal," and is sold during transit. In the case of the free coal, reconsignment during transit is, of course, the practice. It is alleged by the complaints that reconsignment is further required because the unusual delays in the movement and carrier's failure to deliver coal in the order in which it is shipped from the mines makes it necessary for the coal brokers to supply their contract and order demands from time to time with substitutions of free coal.

The coal moves to Milwaukee on a proportional rate. Coal actually delivered in Milwaukee for local consumption paid, at the time of the complaint, from the Kanawha fields a rate of $2.50 a ton. Coal going through Milwaukee for delivery to destinations beyond was charged a proportional rate of $1.90 per ton. This rate has since been increased to $2 per ton. Beyond Milwaukee it pays the full local rates of the delivering carriers. The defendant, the Pere Marquette R.R., has engaged extensively in this transportation. It receives the coal from Eastern carriers at Toledo, Ohio, and moves it thence to Ludington, Mich., a distance of about 273 miles. From Ludington the traffic is carried on the Pere Marquette's car ferries across Lake Michigan, a distance of 97 miles to Milwaukee, where the Pere Marquette makes connection with the Chicago, Milwaukee & St. Paul. It is also ferried to Manitowoc, Wis., where connection is made with the Chicago & North Western and the Soo Line.

At Milwaukee, the Pere Marquette has no extensive terminal, but only an interchange track connecting the car ferry with the tracks of the Chicago, Milwaukee & St. Paul road. This track accommodates about 200 cars. The Pere Marquette maintains no motive power in Milwaukee, and the service of switching the cars from the car ferries to the interchange track and subsequently, in the case of outbound movements, to the tracks of the St. Paul road is done by the locomotives and employees of the latter road under a contract for this service with the Pere Marquette.

Reconsignment Must Precede Arrival of Cars at Reasonable Distance from First Destination

In speaking of one of the main points at issue, the commission makes another interesting ruling and says:

We . . . held that it would be unreasonable and an unjust burden on traffic for carriers to exact the reconsigning charge without undertaking the duty of giving notice to consignees, thus affording them an opportunity of giving disposition orders before the arrival of the cars at their destination. We stated on the other hand that if the coal dealers, having such notice, were not able to give their reconsigning orders before the cars reached Detroit, it was entirely just and reasonable that they should pay the charge for the reconsignment service. We believe that this rule properly may be applied in the present case."

The Railroads are Asked to Show Whether Coal Rates Are Reasonable

Request has been made of the Interstate Commerce Commission by counsel for the Pittsburg Coal Co. that it shall require of all railroads involved in the advanced-rate cases a definite statement of the actual cost of transportation of coal (bituminous) from mine to point of delivery, differentiating the different elements of cost, such as haulage charges, terminal expense, etc. It has not yet been definitely decided how far the commission will require carriers to go in this matter, as it is recognized that an attempt to provide, in good faith, the data mentioned by the Pittsburg Coal Co. would involve a large statistical expense. Carriers regard the matter with some anxiety, believing that the granting of the request would establish a serious precedent. Besides the request demands of them data which they hardly believe they can secure with exactitude.

HARRISBURG, PENN.

A strike of all the miners in the bituminous District No. 2 on April 1, or the shutting down of all the mines by the operators, or both, may be the outcome of a meeting held on Jan. 9, of the Association of Bituminous Coal Operators of Central Penn.

The subject of dissolving the association was thoroughly discussed.

This was advocated by many members because of the alleged unfairness of the miners in reference to the agreement between the operators and the men which expires on Mar. 31. However, it was decided finally not to disband.

On the other hand, it is understood that, a change will be made in existing wage rates and the operators, it is said will ask the men to submit to a reduction of wages. Such a step undoubtedly would lead to a strike or a total suspension.

During the last year the proceeds have fallen off considerably in this district, due to the numerous petty strikes, which the operators assert were based almost wholly on the "closed shop" proposition and were in violation of the existing contract.

Many members of the association allege it is useless to make a contract with a labor organization that violates it at its convenience and with apparently no officials with power to enforce the terms of the contract. When the motion for dissolution was finally put up to the executive board, six of the members voted to disband and seven members voted to continue.

It is alleged that the mine workers are scheming to circumvent the clause in the existing agreement that provides there shall be no cessation of work for 30 days, pending a failure to reach an agreement.

It is reported a call has been issued for a convention of the mine workers delegates from all locals of District 2 to be held on Feb. 24 fully a month earlier than has been the custom. It is also alleged that the miners are forcing a meeting of the Scale Committee of both sides late in February, so that 30 days shall have expired by midnight Mch. 31, the date when the existing scale goes out.

PENNSYLVANIA

Anthracite

Wilkes-Barre—One of the most important lawsuits to be tried in years, and which is expected to determine for the first time the rights and liabilities of a coal company to mine under public streets, was called before Judge O'Boyle on Jan. 8. It is the equity suit filed by Plymouth Borough against the Plymouth Coal Co., to restrain the latter from mining coal under the borough streets.

This is said to be the first case of its kind to be tried in the anthracite region and the result will have considerable bearing on the mine cave question and the rights of municipalities as against the mining rights of the coal companies and their liability for surface support.

Harrisburg—Charters issued by Secretary of State McAfee, on Dec. 31, for the incorporation of eleven electric companies, to operate in Bucks County are thought to be a forerunner of an important plant which may eventually supply light, heat and power to the city of Philadelphia. The incorporators of the new company are S. D. Warriner, president of the Lehigh Coal & Navigation Co., Rollin H. Wilbur, S. Davids, and P. F. Baker, Germantown.

A few years ago the Lehigh Coal & Navigation Co. began the construction of an electric plant at Hauto in Carbon County, and the fuel is obtained from culm banks controlled by the company. With this advantage over competitors in not having to purchase fuel, the company can manufacture and dispose of electricity at cheaper rates than other companies.

Bituminous

Uniontown — Two large acreages of the Freeport vein of coal in West Virginia were purchased by J. O. Clark. The coal purchased is in two tracts of 510 acres, one being of 245 acres and the other of 265 acres. The coal was purchased from D. E. Runnion, of Strange Creek, W. Va. The tracts are located on Elk River and Birch River, and are near the tracts owned by the Colonial Coal Co., the Farmers' Coal Co., and the Strange Creek Coal and Coke Co., all owned by Uniontown capitalists.

Charleroi — River shipping coal mines in the Monongahela Valley are threatened with forced suspension by the strike of tow boat engineers. All but three towboats have stopped operations. This means that no coal can be shipped by river and as soon as the barges at the different mines are filled the mines will have to stop work until the strike is settled or the boats start to operate.

WEST VIRGINIA

Moundsville—Four men were burned in an explosion of gas which occurred in room 12 of the First St. mine of the Mound Coal Co. on Jan. 9. None of the men was seriously injured. The accident was the result of a pocket of gas accumulating and becoming ignited. The four men who were burned were working in the room at the time the explosion occurred. Between 75 and 150 men are employed in the mine. The explosion was confined entirely to room 12 and caused very little damage to the mine.

TENNESSEE

Knoxville — The Knoxville Iron Co. has sold its Cross Mountain coal mine, near Briceville, to the Cross Mountain Coal Co., which has been organized with a capital stock of $200,000. The price given for the property has not been announced. It is understood that the two companies are in no way connected. The mine involved is that at which the disaster occurred two years ago, resulting in the death of 80 miners.

Chattanooga—It is said that plans are on foot for the amicable settlement of the litigation in which the Dayton Coal & Iron Co. became involved some time ago following the suicide of Peter Donaldson, principal owner, in Scotland. The receivership will be wound up and the company may be reorganized and put on its feet again.

KENTUCKY

Louisville—Formal announcement was made in Louisville last week of the acquisition and merger by the Pittsburgh Coal Co. of six concerns which have handled Pittsburgh coal for a number of years. The consolidation was practically consummated about six months ago, but several details were not completed until recently. The companies included in the merger are Joseph Walton & Co., the O'Neill Coal & Coke Co., O'Donnell & Co., Rabb & Bohmer, Eclipse Coal Co. and the Camden Coal Co. The offices of the company are to be maintained at 121 South Third Street, where Joseph Walton & Co. have done business for a number of years.

Middlesboro—The construction of an electric railway line to connect Middlesboro and Pineville, eastern Kentucky coal centers, as well as a city railway line for Middlesboro, is again being projected, and definite plans may be formed by spring. Mayor J. L. Manring, of Middlesboro, is much interested.

OHIO

Zanesville—The property of the Saltillo Coal Co., consisting of three separate tracts of land and mining rights, was sold at trusetts' sale in Zanesville to attorney E. F. O'Neal for $17,000. It includes a tract located near Cannellville in Muskingum County which is in operation, a tract near Saltillo in Perry County and a tract near Rehoboth in Perry County. A company will be organized to operate the property.

Columbus — A movement for the regulation of coal mines in Ohio, as recommended by the Ohio Mining Commission in its report to Governor Cox, has recently received support from many sides. It is the first attempt on the part of the state government to regulate private enterprises. Coal mines when owned by individuals or corporations have always been classed as private property. The claim is made that when the private enterprise takes on a public interest that overshadows its private rights, the state has the right to say how it may be handled. Lawyers are interested in the proposed measure and the legal problems it will bring with it.

INDIANA

Terre Haute — The executive board of the Indiana Coal Operators Association has adopted a resolution asking the Interstate Commerce Commission to grant a 5 per cent. increase in freight rates asked by the railroads. The resolution calls attention to the advances in wages and other increased costs of operating the roads.

Indianapolis — The Supreme Court of Indiana affirms a judgment of the Greene County Circuit Court for $8000 damages against the Shirley Hill Coal Co. for causing the death of Frank Miller, by failing to keep the roof of a mine in safe condition. The company's appeal was on the ground that the verdict was excessive.

ILLINOIS

Harrisburg—The City Council recently passed an ordinance that no liquor shall be delivered by the express companies, unless the purchaser shall sign an affidavit that the liquor is to be used for medical purposes, and any person who invites a friend to his home or place of business and gives him a drink, is subject to a heavy fine. All clubs are prohibited from keeping liquors in their rooms. Harrisburg is a dry town and is the center of some seventeen or eighteen mines, which produce practically all of the coal in Saline County.

MISSOURI

St. Louis—A general protest has been made by Kansas City business men against an enforcement of the ouster order, recently rendered against lumber companies operating in Missouri, including the Central Coal & Coke Co. Commercial organizations of Kansas City are planning to enter a formal request for a withdrawal of this feature of the decision. If the ouster is enforced, 1075 miners employed in Missouri by the Central Coal & Coke Company will be thrown out of employment. The operating company, would, of course, have the alternative of selling its mining property, or inducing another company to operate it.

OKLAHOMA

McAlester—An explosion occurred in Mine No. 40 of the Rock Island Coal Co. at Gowen on Jan. 2, killing John Cronis, shot-firer. Another shot-firer in another part of the mine escaped unhurt and was rescued the next day by the party which found Cronis' body. The company will sustain heavy financial loss by reason of the explosion, and 300 miners will be out of employment until repairs can be made.

COLORADO

Cañon City—Arrangements have been completed whereby the convicts at the state penitentiary will mine coal to be used at that institution and at the Buena Vista asylum. This step was taken because the coal companies have been unable to furnish the necessary fuel. Gov. Ammons was one of the parties to the agreement whereby the prisoners will work mine No. 5 near here.

Trinidad—Miners who left the district when the strike was called on Sept. 23 are returning to work in southern Colorado in large numbers, according to reports recently received.

NORTH DAKOTA

Shields—A big lignite coal mine will be opened on the Standing Rock Indian reservation, a few miles south of here, next spring. The district in question is underlaid with a splendid quality of lignite, and the opening of the mine (for which the financial features have been arranged) will give employment to a large number. It is proposed by the operators to give employment particularly to the Indians.

WASHINGTON

Spokane—The Oregon - Washington R.R. & Navigation Co. has announced a voluntary reduction of 45c. a ton on coal from the Wyoming field to Spokane and vicinity, effective immediately, to meet competition from the northern Wyoming field, where rates were ordered reduced by the Interstate Commerce Commission. The rate is reduced to $4 a ton. In addition the railroad will, commencing February, switch coal to industries on other lines in Spokane without switching charge.

RECENT COAL AND COKE PATENTS

Coal Separator. G. H. Elmore, Joplin, Mo. 1,077,876, Nov. 4, 1913. Filed July 7, 1905. Serial No. 268,647.

Stoker. P. L. Crowe, Jersey City, N. J. 1,077,872, Nov. 4, 1913. Filed Oct. 1, 1907. Serial No. 395,466.

Coke Quenching and Conveying Apparatus. A. Brunner and W. Schondeling, Leipzig-Gohlis, Germany. 1,077,255, Nov. 4, 1913. Filed Apr. 30, 1910. Serial No. 558,592.

Furnace. A. O. Gutsch, Sheboygan, Wis. 1,077,405, Nov. 4, 1913. Filed Nov. 18, 1912. Serial No. 732,106.

Gas Producer. W. O. Amsler, Pittsburgh, Penn. 1,077,578, Nov. 4, 1913. Filed Mar. 14, 1910. Serial No. 549,168.

Mining Machine. E. McGowan, Mulberry, Kan. 1,077,419, Nov. 4, 1913. Filed June 14, 1912. Serial No. 703,683.

Bit for Mining Machines. J. J. Moore, Springfield, Ill. 1,077,542, Nov. 4, 1913. Filed Apr. 15, 1912. Serial No. 690,793.

Mechanical Stoker. W. P. Starkey, Harrisburg, Penn. 1,077,494, Nov. 4, 1913. Filed Nov. 19, 1908. Serial No. 463,488.

Steam Superheater for Locomotive and other Smoke Tube Boilers. J. G. Robinson, Manchester, Eng. 1,077,641, Nov. 4, 1913. Filed July 26, 1912. Serial No. 711,681.

Mine Shot Firing System. G. I. Rawson, St. Louis, Mo. 1,078,463, Nov. 11, 1913. Filed May 4, 1909. Serial No. 493,792.

Boiler. T. T. Parker, New York, N. Y. 1,078,252, Nov. 11, 1913. Filed May 28, 1913. Serial No. 770,394.

Mine Shovel. J. C. Cartmill, Lead, S. D. 1,078,255, Nov. 11, 1913. Filed Oct. 5, 1912. Serial No. 724,141.

Apparatus for Regulating Supply of Steam to Gas Producers. C. H. T. Alston and P. T. Houston, London, Eng. 1,078,480, Nov. 11, 1913. Filed June 28, 1913. Serial No. 776,414.

Cutting Bit for Chains of Mining Machines. C. N. Barton, Harrisburg, Ill. 1,078,082, Nov. 11, 1913. Filed Feb. 10, 1913. Serial No. 747,397.

Grate. G. M. S. Tait, Washington, D. C. 1,078,071, Nov. 11, 1913. Filed Nov. 4, 1912. Serial No. 729,482.

Water Seal for Gas Producers Working with High Pressure Blast. A. von Kerpely, Vienna, Austria-Hungary. 1,078,148, Nov. 11, 1913. Filed Dec. 21, 1912. Serial No. 737,974.

Boxing for Coal Drilling Machines. A. F. Derwy, Pittsburg, Kan. 1,079,289, Nov. 18, 1913. Filed Jan. 4, 1912. Serial No. 669,501.

Coke Drawing Apparatus. J. Hayes, Uniontown, Penn. 1,079,126, Nov. 18,1913. Filed June 18, 1913. Serial No. 774,456.

PERSONALS

J. C. Law, of Carbondale, Penn., was in New York Thursday of last week on a short business trip.

Frank Clark, who has been mine superintendent for the Piney Mining Co. for the past several years, has accepted a position at one of the operations of the Raleigh Coal Co.

E. W. Luton, of Columbus, Ohio, who is well known in coal circles in Indianapolis, has taken the position of Indiana representative for the New York Coal Co., of Columbus, in the place of Arch Grossman, resigned.

W. J. Brown, outside foreman at the Phœnix Park Colliery, has been appointed superintendent of the Philadelphia & Reading Coal & Iron Co.'s collieries in the Ashland district, to succeed W. A. Sauerbrey, resigned.

A. Vernon Orner, civil and mining engineer, recently with the firm of Hess and Bouton of Dubois, Penn., has been appointed chief engineer and superintendent of the Panther Run Coal Co. at Pardus, Jefferson County, Penn., succeeding Henry Redding the retiring superintendent. Mr. Redding has been with the Panther Run Coal Co. for the past 11 years and expects to retire from active business, while Mr. Orner is probably the youngest superintendent employed by any coal company.

OBITUARY

Stephen Harris Harrington, president of the Harrington & King Perforating Co., Chicago, Ill., died recently.

Grant J. Hamilton, 59 years old, a coal operator of Argentine, Penn., died at his home there on Jan. 6. Mr. Hamilton was general superintendent of the Standard Coal & Mining Co. and superintendent of the Mutual Coal Co.

Chas. Campbell, age 67, recently died at his home at White Gables, Kansas City. He was prominent in commercial and financial circles in Kansas City, and was President and Chairman of the Board of Directors of the Central Coal & Coke Co. He began his career at the age of 15 years, as a grocer clerk at Iowa City, Iowa, and died a millionaire.

E. E. Shumway, President of the Rocky Mountain Fuel Co., and well known financially throughout the West, died, Jan. 11, at his home. Mr. Shumway became ill after having superintended the removal of the bodies of 37 men from the Vulcan Mine at New Castle, after an explosion, Dec. 17. The coal strike also is said to have impaired his health. Mr. Shumway, who was 51 years old, is survived by a widow, two daughters, a son, and two stepsons.

Bernard Corrigan, president of the Kansas City Midland Coal & Mining Co., operating mines at Novinger, Mo., died in Kansas City on Jan. 6 of heart disease. Mr. Corrigan was 66 years old. He was the leading figure in the operations of the mining company, of which he was head, but held many other offices during his career. He was for nine years president of the Metropolitan Street Railway Co., of Kansas City, resigning in 1910. Several sons are connected with the Kansas City Midland Coal & Mining Co., and one of them probably will be made president. Mr. Corrigan's estate was worth something over a million dollars, being smaller than expected.

CONSTRUCTION NEWS

Birmingham, Ala.—The Woodward Iron Co. announces that it will start work immediately upon the construction of 30 modern byproduct coke ovens.

Ellwood City, Penn.—The National Coal & Ice Co. has let the contract for a steel coal tipple to the Niles Forge Co.; work will be started in the near future.

Lima, Ohio—The 300-ton coal dock for the Lake Erie & Western Ry. at Lima, Ohio, has been completed by the Oval Construction Co. of Chicago and turned over to the railway company.

Waynesburg, Penn.—The Pennsylvania Railroad will soon make an extension of its lines to tap the new coalfield recently acquired by the Youngstown Sheet & Tube Co. in Greene County.

Brownsville, Penn.—The Denbeau Coke Co. is planning to construct 64 additional coke ovens at its mine near here. The company has 236 ovens, and the addition will bring the number up to 300, all of which are of the most modern type.

Canton, Ohio—The American Mine Door Co. has just fininished shipping an order for 53 machines to the Clinchfield Coal Corp., for their Dante and Dumps Creek operations. It also filled the last of an order for 75 machines last week for the Illinois mines of the Madison Coal Corp., St. Louis Mo.

Columbus, Ohio—The announcement is made from lake ports that 15 steel freighters are being constructed during the winter months to be placed in coal trade at the opening of navigation in 1914. A number of these boats are to take the place of boats destroyed in the severe storms of last November.

Artemus, Ky.—The recently organized Cumberland R.R. Co. is pushing its plans for the construction of a line of railroad from Wheeler, Ky., to Jellico, Tenn., a distance of 24 miles through a rich coal-mining country. The offices of the company are located for the present at Artemus, Ky., in charge of T. H. Hayden, general manager.

Hebron, N. D.—Plans will be made in a few days for the reconstruction of the state experimental lignite briquetting plant, which was recently destroyed by fire. Dean E. J. Babcock, of the School of Mines, who has charge of this plant, is not certain just when the task will be completed, but he anticipates the success of the movement within a short time.

NEW INCORPORATIONS

Chicago, Ill.—The Chicago & Harrisburg Coal Co., of Harrisburg has increased its capital stock from $55,000 to $1,000,000.

Springfield, Ohio—The Springfield Ice & Coal Co., of Springfield, Ohio, has filed papers with the Secretary of State, increasing its capital stock from $122,000 to $250,000.

Richmond, Va.—The Felton Coal Co. has been incorporated at Tacoma, Va., with a capital stock of $10,000. M. F. Hatfield is president and G. F. Neal secretary, both of Tacoma, Va.

Dover, Del.—Elijah & Winne, recently incorporated at Dover, Del., with a capital stock of $25,000 to manufacture and deal in anthracite and bituminous coal and its products.

Mayland, Tenn.—The Mayland Coal & Coke Co. has been incorporated with a capital stock of $50,000. J. S. Cline, C. H. Sells, T. F. Brown and others are among the incorporators.

Chattanooga, Tenn.—The Kentucky Coal & Iron Co. has filed articles of incorporation. The company will operate coal mines and will probably establish iron furnaces near Chattanooga.

Brazil, Ind.—The Peacock Coal Co. has been organized by Mayor John Bray, and will at once locate a shaft on Bray's farm near Billtown where there is a bed of bituminous coal 6 ft. 8 in. thick.

Indianapolis, Ind.—The Cedar Creek Coal Co. has been incorporated here, with $10,000 capital stock, to deal in coal and coke. The directors are A. V. Grossman, H. Grossman and C. P. Bartlett.

Wellston, Ohio—The Blue Jay Coal Co., of Wellston, Ohio, has been incorporated with a capital stock of $10,000 to mine and deal in coal. The incorporators are W. S. McCloud, H. A. Goddars, Grant McGhoe, John H. Yeager, and C. E. Littler.

Poteau, Okla.—The Claco Mining Co., with a capital of $50,000 has been organized by J. T. Roland and Hugh Dook of Milton, L. S. Bayrell, of Frederick, F. L. Mercer and C. G. Weise, of Poteau and Ed Hayes, of Witteville. The company will open an entirely new coal field at Traby Prairie, near here.

Indiana, Penn.—The Conemaugh Smokeless Coal Co. has been organized and will develop 2000 acres of coal in Indiana County, near the Westmoreland County line. The coal is owned by the Operators' Coal Co. This company has big holdings in Indiana County, having recently acquired 1700 acres. It now owns 4500 acres in the Indiana field.

INDUSTRIAL NEWS

Woodlawn, Penn.—Fire destroyed the coal tipple at the Alliquipa plant of the Jones & Laughlin Steel Co., causing a loss of about $8000.

Johnstown, Penn.—The Cramer Coal, Coke & Stone Co. has begun shipments from a 3000-acre tract which it is developing near here.

Brush, Colo.—While drilling a well on the ranch of Lew Forrest northwest of this town today, a 3-ft. vein of lignite coal was struck at a depth of 6 ft.

New Castle, Penn.—It is possible that the mines formerly operated by the Beaver Coal & Coke Co. will be reopened if present plans of the Board of Trade are carried out.

Frostburg, Penn.—John and William Merbach have discovered a rich vein of coal between Frostburg and Meyersdale. They will begin shipping coal just as soon as tracks can be put in.

Macdonaldton, Penn.—The Roberts & Schaefer Co. has closed a contract with the Brothers Valley Coal Co. for a steel tipple and Marcus conveyor to be installed at Macdonaldton. The contract price for this equipment is in the vicinity of $16,000.

Sharon, Penn.—The production record of the Carnegie Steel Co.'s coking plant was broken in 1913 by approximately 25,000 tons of furnace coke, although only one of the four batteries of ovens was in operation during December. The total output for the year was about 445,000 tons.

Henderson, Ky.—The People's Mining Co., recently acquired 65 acres of coal property from W. T. Lambert, the high price of $46 an acre being paid, this being an unusual figure for that section. A tract of 54 acres was purchased by the same company from J. W. Tood at $25 an acre.

Columbus, Ohio—The annual meeting of the Ohio District of the United Mine Workers was held in Columbus, Jan. 13. Delegates were present from all the mining districts of the state. One of the principal matters considered was the recommendation that the Ohio Mine Commission eliminate screens.

Seattle, Wash.—The 840 union coal miners of the Pacific company's mine at Black Diamond have returned to work, the conditions at which the men complained having been adjusted. After two men had been killed in the mine recently in an explosion, the miners refused to work longer until safer conditions prevailed.

Washington, D. C.—Complaints to Attorney General McReynolds from several Eastern cities that the price of hard coal is soaring, charge that the Pennsylvania state tax on every ton of anthracite mined within its borders is responsible. The attorney general has replied to complainants that some individual will probably bring suit to test the law, and if the department finds it advisable, it may intervene.

Fort Smith, Ark.—There is a prospect of the sale of several thousand acres of coal lands in Logan, Johnson and Yell counties to persons said to have the assistance of English and Dutch capitalists. It is officially announced that negotiations are on for the transfer of land and that an option has been secured. The tract is said to consist of 15,000 acres, most of it in Logan County, east of Scranton.

Washington, D. C.—There is absolutely no reason, according to S. C. Elliott, general counsel for the White Pass & Yukon R.R., why the Alaska Railway Bill, which is soon to come up for consideration in committee after Congress convenes should become a law. According to Mr. Elliott, the proposed legislation would involve the expenditure of $35,000,000 without any certainty of returns, and he asserts the belief that President Wilson is favoring the bill through a mistaken idea.

Pittston, Penn.—The Pennsylvania Coal Co. has received a severe set back in the Schooley Colliery operations, which for several years back have been going on. Recently two powerful electric pumps were installed and the work of lowering the water in the shaft had been progressing very encouragingly, but on Jan. 5 an unlooked for rush of water from some unknown source came upon the workmen so suddenly that the pumps and all apparatus were covered over before they could be withdrawn. The machinery which was but recently purchased at a great expense was covered over with mud and other debris, and it will be necessary to completely clean it before it can again be put to pump the water out of this mine.

Nordegg, Alberta—Development of the extensive property of the Brazeau Collieries, Ltd., near the new townsite of Nordegg, 120 miles west of Blackfalds, Alberta, is proceeding rapidly, and the first shipment will be made in January. The mine is situated on the new Canadian Northern Ry. branch from Stettler, the steel on which is now being laid as quickly as possible. Development has been proceeding for the last 18 months, during which 1400 ft. of tunnels have been driven through two seams 14 and 7 ft. thick respectively.

The coal is of a high grade suitable for locomotives. There are 35,000 tons now ready for shipment, which is under contract to the Canadian Northern. An uptodate plant with a capacity of 2000 tons per day has been contracted for to be installed in running order by Sept. 1, 1914, and in the meantime a temporary chute capable of handling 400 to 500 tons per day has been installed. When fully developed the mines will employ 450 men.

Coal Trade Reviews

General Review

Heavy storms and low temperatures cause a better tone, although situation is still dull. Anthracite output in excess of demand. Bituminous operations much curtailed. Some demurrage coal forced on the market but prices generally well maintained.

Generally severe weather in nearly all parts of the country during the first of the week, started an active movement in the retail hard-coal trade. The change has not been of sufficient duration to affect wholesalers as yet, but there is a better tone generally in all departments. However, producers are still compelled to make concessions in order to move tonnage, while dealers are already beginning to anticipate the possibility of carrying some winter-priced coal over after the Apr 1 discount goes into effect. The production continues in excess of demand, and the situation is particularly unfavorable at tidewater.

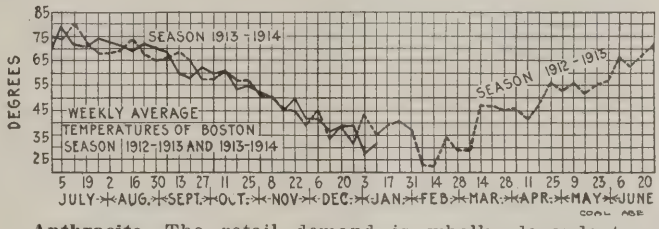
The recent cold weather has failed to help the bituminous market, and there is a feeling gradually developing among producers that a general slump can only be prevented by a strict curtailment. Even now mines are working under a heavily restricted output, while consumers are endeavoring to cancel old orders. Little spot business of any kind is being negotiated and off qualities are particularly dull.

Although a decided improvement on domestic business is expected in the Pittsburgh district as a result of the sharp fall in temperature, the demand at the moment is light; a resumption in general manufacturing effective the first of the year will help the situation some, but the absence of sustained cold weather has had a depressing effect. Conditions in Ohio show some improvement as a result of the more seasonable weather and an increase in manufacturing. Anticipation of labor troubles Apr. 1 is also having an effect upon the situation; with the market in its present unsatisfactory condition, operators will be ready to suspend operations indefinitely, if necessary, and the position of the miners is materially weakened.

While shipments from the Hampton Roads piers have fallen off during the week, the effects of the curtailed production over the holiday period are now being felt and accumulations are only about normal. Prices are holding remarkably firm in spite of a general slowing up. The Southern markets are contending with adverse weather conditions and dealers are showing little disposition to buy; an improving tendency is noticeable, but not much change is anticipated before spring.

The anticipated labor troubles next April have had a stimulating effect upon the Middle Western situation, which was also helped out by the colder weather. Large industrial concerns are showing an inclination to increase their stock piles, and the better grades are now commanding good figures. There has been an unexpected shortage of hopper bottom cars. Some demurrage coal is occasionally forced on the market for anything it will bring.

EASTERN MARKET



BOSTON, MASS.

More inquiry for bituminous. The Hampton Roads coals generally dull, but buyers begin to show interest in better grade Pennsylvanias. Anthracite demand also slightly improved, although it is still a weather market.

Bituminous—There is little change in the situation of Pocahontas and New River. When buyers are not seeking to postpone shipments on purchases made several weeks or months ago, they are indifferent, and no improvement is looked for in the immediate future. The off-shore demand is fairly steady, due to rather higher prices on the Welsh coals, and that is the only feature that gives any stability to present prices. The Western demand has fallen off materially and apparently a rigid curtailment is all that will prevent a generally softening market.

Georges Creek maintains its usual firm position. For spot shipment there is only a light inquiry and what tonnage is being moved is almost solely on season contract.

Within the week some buying interest has developed in the Pennsylvania grades, especially those that are more favorably regarded. Prices on these coals are more sensitive to the dull market we are experiencing than is the case with the Southern coals, and the few large buyers who have been waiting developments have now come in for hand-to-mouth deliveries. It is not especially significant but the market is so quiet in every direction that any move, however small, is bound to be noticed. The colder weather has improved the outlook but the fact that there is any reliance on its continuance shows how desperately slow the market is on all grades of bituminous.

Anthracite—The retail demand is wholly dependent on the weather. Just now some scattering business is being had and if the balance of the month is moderately cold there is sure to be a better call for anthracite in New England. The dealers are figuring closely so as not to carry winter-priced coal over into April and so confident are they that the companies can now supply cargoes on short notice that they are reluctant to file requisitions until the need for the coal is plainly evident.

Certain of the New York barge companies that advanced water freights 25c. in November to Boston have once more receded and practically all the anthracite shippers are now on a parity, so far as concerns along-side prices on the domestic sizes.

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$1.00@1.50	$1.25@1.60	$1.67@1.77	
Philadelphia*	2.25@2.75	2.50@2.85	2.92@3.02	
New York*	2.55@3.05	2.80@3.15	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.80@2.90
Boston†				3.72@3.82
Providence†				3.72@3.82

*F.o.b. †On cars.

NEW YORK

Holiday suspension has resulted in a shortage of some grades of anthracite. Main weakness in the tidewater market. Strike of the bargemen concluded. Soft coal easy and outlook unsatisfactory.

Bituminous—The recent bargemen's strike in New York Harbor came to an abrupt end when two or three of the largest individual towing concerns granted the increase demanded, five days after the strike started. It is said that this was conceded more for the purpose of squeezing out some of the smaller concerns who cut rates in time of slack business.

The market is still easy. The demand is light, and while there are no direct reports of demurrage coal, rumors of occasional lots being offered at $2.40@2.55 would seem to indicate that the market is being forced. Concerns that failed to contract during the active trade last summer have had a rather severe lesson in marketing coal; such operations are all generally closed down now. The car and labor supply are both fully up to requirements, but incipient labor troubles are still an aggravating condition in the mining regions. The anticipated suspension in mining Apr. 1, pending the arrangement of a new wage scale in the central competitive district, will, no doubt, cause some flurry through March, but conditions point to a quiet market through April and May if not longer. If an agreement is not reached on the wage-scale problem, there will be no business to negotiate, while if no suspension occurs, consumers generally will be so heavily stocked that they will not be in the market for some time to come. We quote the New York market off on some grades as follows:

West Virginia steam, $2.60@2.75; fair grades of Pennsylvania, $2.60@2.65 good grades of Pennsylvania, $2.75@2.85; best Miller Pennsylvania, $3.10@3.20; George's Creek, $3.15@3.25.

Anthracite—A sharp fall in temperature, accompanied by a heavy wind, approximating a gale, has started an abrupt rush for coal in retail circles. The early part of the week saw the coldest weather experienced in New York in 14 years. The changed conditions have not been of sufficient duration to affect the wholesale business yet; it is variously estimated that from one to three weeks of more or less continuous low temperatures will be required to effect any material difference in conditions. Unless there is considerable cold weather between now and Apr. 1, the companies may carry some winter stocks over into the summer business.

Full-time work at the mines is not yet general, although from weather indications the first of the week, production will soon be rapidly increased. Rice coal at the upper ports is in short supply as is also No. 1 buckwheat. The suspension in December has resulted in a shortage of egg, and there is not much pea at tide; chestnut is generally strong. The bituminous strike talk Apr. 1 may create some activity in the steam grades through February and March. Generally speaking, the main weakness in the market has been on tidewater business, the all-rail situation, as a rule, being comparatively strong.

We quote the New York hard-coal market on the following basis, the figures given not including the Pennsylvania state tax of 10c. on the domestic grades and 5c. on pea coal, as follows:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.00	$4.50@5.00	$5.05	$4.45@4.95
Egg	5.25	5.15@5.25	5.30	5.10@5.20
Stove	5.25	5.25	5.30	5.15@5.20
Chestnut	5.50	5.50	5.55	5.35@5.45
Pea	3.50	3.50	3.50	3.45
Buckwheat	2.75	2.75	2.70@3.45	2.25@2.70
Rice	2.25	2.25@2.35	1.95@2.20	1.75@2.20
Barley	1.75	1.60@1.75	1.70	1.45@1.70

PHILADELPHIA

Hard-coal trade shows signs of improvement with the appearance of more seasonable weather. Increase in orders slight, however, and supply remains greater than demand.

Under the influence of more seasonable weather the local anthracite trade improved last week, but it has by no means reached a satisfactory state for the operator and dealer. The increase in orders was light, and the supply is still in advance of the demand.

With plenty of coal at hand the producers in many cases have been forced to make concessions in order to sell their product, but despite that fact less coal was sacrificed last week than in the closing week of 1913. There is little expectation of marked improvement in the trade until weather conditions are such as to bring about a greater consumption. Meanwhile dealers here are merely marking time.

The bituminous coal trade showed a slight improvement last week. Small advances in prices occurred in several grades, but there was little significance to these changes as the meager increase merely indicates getting back into the regular routine after the holidays.

BALTIMORE, MD.

Colder weather has helped the anthracite trade. Bituminous continues flat, with prices showing little or no change. Situation at the piers is not encouraging.

Real cold weather has proved quite a boon to the hard-coal trade here. During the past week the local dealers, especially those handling the smaller trade orders, have been busier than for any priod since winter set in. Continued warm weather had induced many to get along with scant supplies, and the change to fairly heavy orders is quite a welcome. Steaming sizes were reported easy the past week, the only scarcity with some dealers being in the smaller prepared grades, for which there was quite a rush in spots. Movement from the mines was easy, however, and no trouble in supply generally is anticipated unless blizzard-like conditions develop.

Interest continues deep here as to the effort to consolidate 20 of the largest retail concerns of the city. Some of these are said to be holding out for more money than is offered by those behind the merger, and the entire proposition looks uncertain for the time being.

Colder weather has so far failed to strengthen the soft-coal trade. Demand continues light for Maryland, West Virginia and western Pennsylvania products as a whole. In West Virginia the soft coals are bringing anywhere from 80@90c., while low-grade Pennsylvania steam coals are selling around 90@95c., and best grades at $1.25.

Coastwise movement continues fair on December chartering, but a lack of chartering has recently developed for late January and February loadings. This includes coastwise as well as foreign trade.

CENTRAL STATES

PITTSBURGH, PENN.

Coal demand poor, but slightly improved; circular prices being shaded, except with slack, which readily commands premiums; mine operations at about 50%. Coke market dull but firm.

Bituminous—On the whole, demand for coal is very light, but it has improved somewhat in the past few days. Many mills were closed over the holidays, and their resumption effects an increase in contract shipments, although resumption is only partial since the mills are operating at only about 60% of capacity. Domestic demand has experienced a slight increase, and a greater increase is to be expected before the week is out as a cold snap has just arrived. Mine operations generally are estimated at 50% of full capacity, the reduction being effected chiefly by operating on alternate days, few mines being closed altogether as it is deemed important to hold organizations together. Prices are rather irregular for mine-run and screened coal, circular figures being frequently cut, while slack is scarce and invariably commands a premium. Operators have themselves bought at $1, while sales to consumers are frequently at $1.10@1.15. Circular prices are: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¾-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The market has become quiet. Only two large interests among the operating furnaces failed to contract, and they are quite unwilling to pay prices asked. The $2 operators are reported firmer than ever on this figure, while most of the cheaper coke has already been disposed of. Prompt is in light demand. The next activity will be when the time arrives for arranging February tonnages, since several of the recent buyers covered for January only. We quote: Prompt furnace, $1.90; contract furnace, $1.90@2; prompt foundry, $2.40@2.65; contract foundry, $2.40@2.65, per ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended Jan. 3 at 252,151 tons, an increase of 16,000 tons, and shipments at 250,787 tons, an increase of 17,206 tons. The small tonnage the previous week had been due to the holidays.

BUFFALO, N. Y.

Production heavily curtailed and market fails to show any improvement. Consumers refuse to see any serious possibilities in the impending wage-scale agreement. Prices generally weak.

Bituminous—The situation is not materially changed. The weather has been somewhat more wintry, but a thaw has again intervened, and no further stocking up is being done even where more room is available. Mines are running as slow as possible. As a rule, all consumers have more coal than they wish to carry and they are quite uneffected by stories of spring strikes.

Meanwhile the operators and miners are beginning to hold meetings, by way of getting into line for the new wage scale. If the miners insist on the concessions that they are now making up it will take a good part of the summer to arrive at any sort of agreement. Operators are at present quite indifferent to a lengthy shut-down and if the situation does not improve before April they will welcome suspension lasting until the market is clarified and it is possible to sell coal again at a profit. Had the trade remained strong, as it was expected to early last fall, the producers would have been quite at the mercy of the miners.

There are few sellers still claiming that they are getting old prices, although the nominal market is still quotable: $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run and $2.25 for slack, with slack doing better of late than sizes. Allegheny Valley prices are about 25c. lower than Pittsburgh.

Coke—There is no improvement in the coke trade and dealers find it difficult to get former figures, based on $4.60 for 72-hr. Connellsville foundry. The light demand would make it appear that the actual consumption of pig iron was decidedly small.

Anthracite—Occasionally a shipper reports that the demand for anthracite has improved but the larger handlers agree that the late showing of winter has had little effect. Based on the consumption so far, there are a good many members of the trade who are ready to declare that they have coal enough to last them till April.

Shippers says that a severe cold snap will change the situ-

ation. Reports come in of heavy overstocks at upper-Lake ports, but indications are that these are all more or less overdone. A severe last half of winter would use the surplus up. Not much Lake tonnage is now being loaded here, as it is hard to get and shippers are not anxious.

COLUMBUS, OHIO

More seasonable weather has caused a better feeling in the trade. The movement is larger and some strength is shown in the price list. Unsettled condition because of the wage scale which expires Apr. 1.

The coal trade has regained some of its lost strength due to more seasonable weather and a disposition on the part of some to stock up to guard against a suspension after Apr. 1. The movement of all sizes is larger than the previous week and a better feeling is shown in all mining districts of the state. Coal men generally look for a gradual improvement from this time on.

One of the best features of the market is the better demand for steam grades. This is due to the resumption of many factories which were closed down during the holiday period. Then again some of the larger steam users have started to stock up in fear of a prolonged suspension after the expiration of the present wage scale. Railroads are also increasing their fuel requisitions and the net result is a better tone in that department of the trade.

In domestic circles things are still slow. Dealers stocks are large and they are not disposed to order at this time. It will require considerable cold weather to bring them into the market again. Most of the large householders have laid in their winter's supply of coal and the retailers have to depend upon small orders. Prices are holding at the level which has prevailed for the past two weeks. Some cutting is being done by the smaller producers and jobbers but the larger companies are busy maintaining the list. There is some demurrage coal on the market which tends to reduce prices.

The output in Ohio is gradually increasing although it is still far below the normal figures. In the Hocking Valley district the production is estimated at 50 per cent. of the average and the same is reported from Pomeroy Bend and eastern Ohio. In the strictly domestic fields the output is probably 40 per cent. of the average.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.75 @ 1.70	.....	$1.90 @ 1.80	$1.70 @ 1.60
3-4 inch	1.50 @ 1.45	$1.20 @ 1.15	1.60 @ 1.40	1.50 @ 1.45
Nut	1.30 @ 1.25	.....	1.50 @ 1.40	1.30 @ 1.25
Mine-run	1.30 @ 1.25	1.10 @ 1.05	1.30 @ 1.25	1.30 @ 1.25
Nut, pea and slack	0.80 @ 0.75	.....	0.90 @ 0.85	0.80 @ 0.75
Coarse slack	0.70 @ 0.65	0.95 @ 0.90	0.80 @ 0.75	0.70 @ 0.65

DETROIT

Production restricted and prices heavy. Supplies large and customary winter business has failed to appear. Possibility of a suspension in April creating some interest.

Bituminous—Production in the various mining regions during the past week has been about 50 per cent. capacity. This was due, of course, to a lack of demand, which latter has also resulted in a sagging market, in spite of the efforts of the companies to maintain circular quotations. Even occasional concessions in prices has failed to stimulate business.

Car and labor supply have ceased to be factors in the situation. Local industrial concerns are working under restricted operations, and as a result the steam demand is light. The domestic business is lacking in the customary winter volume, and supplies on hand are generally large, while the demand is small, fluctuating according to temperatures. The possibility of a suspension in mining Apr. 1, when the present wage-scale expires, is the only uncertain feature in the market.

The local prices are quotable on the following basis:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump	$1.65	....	$1.50	....	....	$2.50	$2.50
Egg	1.65	....	1.50	....	....	2.50	2.50
Nut	1.20	....	1.10	....	....	....	....
Steam lump	1.10	....	1.10	....	....	....	....
¾-in. lump	1.00	$1.05	1.05	$1.00	$1.00	....	....
Mine-run	0.90	0.95	1.00	1.00	1.00	1.35	....
Slack	0.80	0.80	0.80	0.80	0.80	....	....

Anthracite—The market is dull with practically no business being negotiated and with scarcely any coal coming in.

Coke—Coke remains heavy, although it still seems to be doing better than any other line. Connelsville sells at $2; Semet Solvay, $2.85, and gas house, $2.75.

LOUISVILLE, KY.

Operators forcing the market in order to keep mines running. Consignment shipments frequently made. Market glutted and prices suffering acutely under adverse conditions.

Unseasonably mild weather for this season, in spite of indications that there would be some real winter, has kept the demand for fuel, down to the lowest possible mark; it can almost be said that the local market is demoralized. The necessity of disposing of the coal produced has forced operators and wholesalers to extreme measures, as an alternative to a complete shutdown. Shipments on consignment, without orders, are becoming common, and traveling representatives of the producers are doing everything in their power to dispose of domestic coal at almost any price. While there is undoubtedly some consumption of the domestic grades, there is still not sufficient being used to make much of an impression upon the stocks which have accumulated. In consequence, the market has been practically glutted, and it seems that only a protracted period of much colder weather than has yet prevailed will help things to any appreciable extent.

The steam market, while in much better shape than the domestic, shows what might be called a sympathetic weakness. In spite of the fact that the production of screenings has been curtailed, prices have undergone a pronounced slump. Western Kentucky nut and slack, usually in fair demand at 65c. was quoted last week down 15c., although this, of course, could not be called the market price. The best grades of Eastern Kentucky block can be had at the purchaser's own figures, $1.65 being eagerly accepted. For block and lump $1.50 is a good price. Western Kentucky domestic could be quoted 50c. lower all around, with light demand. Eastern Kentucky screenings, nut and slack, are in slow demand at 85 cents.

HAMPTON ROADS, VA.

Holiday season has reduced the demand and lower prices are frequently heard. Prices holding fairly well though some cutting.

While coal shipments from Hampton Roads during the week have been fair, they will hardly compare with the dumpings for the first week of December. The holiday season is no doubt responsible for most of the light demand during the past two weeks. However, the accumulation of coal is little above normal as shipments fell off considerably on account of the miners laying off several days during the holidays.

Coastwise shipments of the week have been to Jacksonville, Tampa, Charleston and the New England ports while foreign movement went to Kingston, Dakar, Media Luna, St. Thomas, Santiago, Port Castries, Naples, La Plata and Taltal.

While the demand for all grades has been light there has been little cutting in prices the majority of suppliers holding out for the circular. Some sales, however, have been reported at around $2.75 and lower. New River and Pocahontas run-of-mine has been practically the only coal moving from Hampton Roads during the week.

SOUTHERN AND MIDDLE-WESTERN

BIRMINGHAM, ALA.

Lump coal slightly improved. Steam grades easy and blacksmith normal. Furnace and foundry coke quiet. Some sales of pig iron for first-half delivery. Car situation fairly satisfactory.

There is really not much change in the market this week. Lump coal has enjoyed a slightly better trade, but with prices somewhat under the regular schedule. On account of the exceedingly mild winter so far, the dealers are in no hurry to accummulate large stocks. The retail yards report a better volume of business the last ten days than for some time, which is an encouraging sign. Steam coal is still quiet, though prices are remaining about stationary. Not much improvement can be looked for in this line until spring.

After the spurt on furnace coke, caused by heavy shipments West, made in order to accummulate stocks before the $2 increase in freight, coke has again assumed a normal condition, which is far from satisfactory to the manufacturers. Blacksmith coal is moving on about as usual. The car situation seems to be slightly improved for the time being.

NEW ORLEANS

Stocks on hand large, but supplies are being received in normal volume. Large orders to go forward from Pittsburgh on January rise. Use of anthracite increasing. Street railway company awards contract.

While stocks of coal in New Orleans are large, due to the

mild weather and some falling off in the bunker trade, there will be no decrease in the coal orders to come down the river with the January rise. From the Alabama fields tonnage is decreasing little if any and stocks are accumulating rapidly. One of the features of the local trade is the increased use of anthracite. Not many years ago scarcely a ton of such coal was used in this city but it is now quite general.

A contract for 175 tons of bituminous coal has been let by the street railway company to the Pratt Consolidated Coal Co. Representatives here of Alabama operators report that they are having great difficulty in disposing of their tonnage. Some curtailment is in progress and unless demand picks up quickly, it is likely to become more extensive.

INDIANAPOLIS

The approach of the expiration of the wage contract in the central competitive fields has brought out increased orders. Prices are firmer. Shortage of hopper-bottom cars.

January is producing some weather that is up to the general standard for the month, which has been good for the coal industry, both mining and distributing. The mining end has also been benefited by the approach of the time for making a new wage contract between operators and miners. The negotiations in the past have sometimes been prolonged until after Apr. 1, when the new contract should begin. It has thus become customary for consumers of coal to stock up as this date approached, in order to tide their needs over this idle period. An effort is being made to continue work at the mines this year in case of a delayed agreement, but consumers do not appear to be willing to take any risks. Already there is an increase in orders from the largest industrial consumers and the railroads will soon be increasing their piles.

Whether the larger business that some of the operators report is responsible for an unusual shortage in hopper cars is not known. These are generally plentiful and the gondolas scarce, but the position is now reversed. Most of the large consumers have facilities for handling the hoppers, and a better demand for coal from them would leave fewer available.

There has been no change in mine prices, but they are held more firmly. Retail quotations in this city are still on the basis set Sept. 20. Some of the largest dealers say that a cold spell this month or next will probably make mine prices higher, especially under an expected larger demand, due to wage contracts expiring, and that any advances at the mines will be promptly followed by retailers. Others intimate that any increase would be arbitrary, as stocks are large and there is yet much undelivered coal bought at old prices.

CHICAGO

Indications of a revival, but present conditions are far from satisfactory. Little business is being transacted by anthracite dealers, some of them having shut off shipments entirely. There is small demand for Hocking and the coke trade is light. Prices on several coals have been cut.

While there has been some improvement in local conditions the general situation still remains unsatisfactory. Inquiries received from retail dealers indicate a stronger disposition to buy, but it is conceded that any increase in production or shipment at present would cause a further slump in the market.

Dealers in anthracite coal report an unusually light volume of orders. All sales agents have curtailed shipments and some of them have shut off enirely until conditions improve. Receipts of all-rail coal are far in excess of sales and there is scarcely any movement of anthracite from the docks to interior points. In a number of instances quantities of this fuel have been forced upon retailers at exceptionally low prices to avoid demurrage charges.

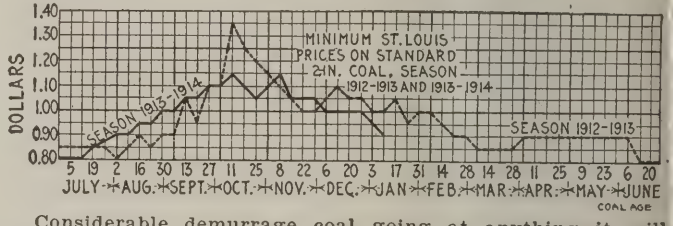
There is scarcely any demand for Hocking, the circular price for which has been reduced from $2 to $1.75 by the larger producers. Some of this coal on track subject to demurrage is being disposed of at prices under circular. There has also been a reduction in the price of Franklin County coal. The major producers have named $1.75 as their circular figure and sales at prices ranging between $1.50 and $1.60 have been recorded. The coke market is dull. Scarcely any of this fuel is being absorbed by the domestic trade, about the only activity being in sales to Western smelter interests which have sought this market on account of labor difficulties in the West. Sales of furnace and foundry coke continue light.

Indiana mines are running chiefly on steam coal for the purpose of handling contracts entered into several months ago. Springfield operators are endeavoring to adhere to $1.50 for domestic coal, but sales at $1.25 are not uncommon. Producers of splint have reduced their price on 1¼-in. lump to $1.75 and Eastern Kentucky block coal is selling at from $1.75 to $2.25.

Prevailing prices at Chicago are:

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic lump	$2.32	$2.55@2.80	$2.27	
Steam lump	1.97		1.97	
Egg		2.55@2.80		$4.30
Mine-run	1.87	2.30	1.87	3.45
Screenings	1.47	1.75@1.85	1.47@1.57	

Harrisburg quotations are: Domestic lump and egg, $2.55@2.85; steam lump, $2.25; mine-run, $2.25; screenings, $1.75@1.85; No. 1 nut, $2.55@2.85; No. 2 nut, $2.55.



Prices asked for Carterville coal are: Lump, egg and No. 1 washed, $2.55@2.85; No. 2 washed, $2.55.

Coke—Connellsville, $5.25@5.50; Wise County, $5@5.25; byproduct, egg, stove and nut, $4.90@5; gas house, $4.65@4.75.

ST. LOUIS

Practically no change in St. Louis conditions, although the weather is slightly colder. Steam market holding up well. Smokeless and coke not moving and little demand for anthracite.

Market conditions the same as they have been or several weeks. The weather has been slightly colder, but nothing like real winter. Still, there is some domestic demand, just about enough to keep the steam market in a healthy condition. Even at that some of the operators are trying to force business and in many instances they cut prices 10 to 15c. a ton on lump and egg from the Carterville field.

Considerable demurrage coal going at anything it will bring, but the higher grade fuels still command a good figure. High-grade screenings are worth 80 to 85c. In the Standard district lump has sold as low as 90c. and screenings are hovering around 50 to 55c. The local car supply is more than ample and some mines have been idle for many weeks with strings of empties on their tracks.

There is little demand for anthracite and the coke and smokeless markets are glutted with consignment shipments.

The prevailing circular is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump	.....	.....	.....	$0.90@1.00
3-in. lump	.....	.....	$1.40	.....
6-in. lump	$1.25 @ 1.50	$2.25	1.50	1.15@1.25
Lump and egg	1.85 @ 2.15	.....	.....	.....
No. 1 nut	1.15 @ 1.40	.....	.....	.....
Screenings	0.75 @ 0.80	.....	.....	.....

No. 3 washed nut	1.15	.....	.....	.....
No. 4 washed nut	1.05	.....	.....	.....
No. 5 washed nut	0.50	.....	.....	.....

KANSAS CITY

Colder weather has stimulated business. Mine operations are being increased.

All available nut coal is being absorbed without difficulty in the Kansas City market, the only weakness being in the lump situation. The demand for nut seems to be largely responsible for the slow movement of lump.

However, the snappy weather is expected to stimulate all lines and the situation is in better shape than for several months. Dealers are ordering fairly well, and a continuation of present weather conditions will result in full-time mining operations in the near future. Most of the Kansas and Missouri mines are being worked to about two-thirds capacity, the prospects being for an extension of output, rather than the reverse. The market is showing more strength under better weather conditions, though no general advance in quotations has yet been made.

PORTLAND, ORE.

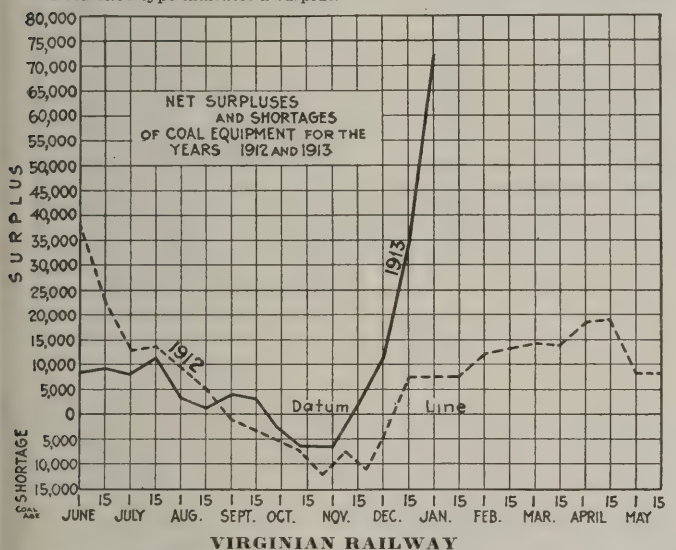
Eastern coal shippers look to Pacific Coast with view of handling cargoes through Panama Canal. Open winter for western Oregon and Washington does not tend to sharpen demand for fuel. Conditions practically unchanged.

The Portland Commercial Club has received inquiries from Atlantic Coast shippers asking for information as to the possibility of extending their markets to the Pacific Coast ports upon the completion and opening for traffic of the Panama Canal. It is believed here that with the opening of the canal and cheaper transportation rates the Pacific Coast states will prove an inviting field for the Eastern coal mines, although the production in the West and on the Pacific Coast is stead-

ily developing. The establishment of large coal bunkers to accommodate foreign shipping on the Columbia is also looked for in the near future on account of the increased shipping, as a result of the opening of the canal.

The weather this winter has been unusually mild and the demand for coal for domestic purposes has not been as heavy as in years past. However, the coldest weather here usually comes in January, February and March, and there is still a chance for the coal man. So far there has been no fluctuation in prices since the advance announced a couple of months ago.

PRODUCTION AND TRANSPORTATION STATISTICS



THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Jan. 1, as follows:

	Surplus	Shortage	Net*
New England Lines	571	0	**571**

VIRGINIAN RAILWAY

The total shipments of coal over this road for November, 1913, were 421,971 tons as compared with 316,504 tons for the same month last year. For the first eleven months of 1913, the shipments were 4,190,394 tons as compared with 3,177,243 tons in 1912.

ANTHRACITE SHIPMENTS

Anthracite shipments for the calendar year 1913, were 69,069,628 tons as compared with 63,610,578 tons in 1912 and 69,954,299 tons in 1911. Production in 1912 was, of course, much curtailed due to the suspension in mining pending the arrangement of a new wage scale.

The feature of the anthracite movement in 1913 was the heavy shipments of the Lehigh Valley. For the first time in the history of the anthracite shipments, this road takes first place in the tonnage movement for the year, exceeding the Reading Co. by 100,000 tons. This is not indicative of a reduced capacity of the Reading mines, or a largely increased capacity of the Lehigh Valley. The Reading sales department was compelled to carry the new 2½% Pennsylvania State Tax throughout the bulk of the year, which materially narrowed the market for their product. Reading was also forced to restrict operations more during unfavorable market conditions, showing an inclination to conserve their supplies rather than attempt to force business.

The shipments for December 1912 and 13, and for the two years were as follows:

	December		12 Months	
	1913	1912	1913	1912
Phila. & Reading	1,058,723	1,223,880	12,914,887	12,852,386
Lehigh Valley	1,062,578	1,108,765	13,011,370	11,791,601
Cent. R.R. N.J.	663,395	760,479	9,092,433	8,342,477
Del. Lack. & West	839,384	850,977	9,903,541	9,065,622
Del. & Hudson	590,158	598,969	7,094,258	6,361,238
Pennsylvania	546,976	543,361	6,351,746	5,548,193
Erie	709,431	667,532	8,192,352	7,435,697
Ont. & Western	191,973	190,539	2,509,031	2,213,382
Total	5,662,618	5,944,502	69,069,628	63,610,578

COAL FREIGHT DECISIONS

I. C. C. No. 4604—Traffic Bureau (Nashville, Tenn.) vs. Louisville & Nashville R.R.

1—Conditions affecting the transportation of coal from Louisville & Nashville R.R. western Kentucky mines to Louisville, Ky., Memphis and Nashville, Tenn., not found to be so dissimilar as to preclude a comparison of the rates from the same fields to the three cities.

2—Rate of $1 per ton on coal to Nashville from Louisville & Nashville western Kentucky mines found to be unreasonable and rate of 80c. prescribed. A like rate from Nashville, Chattanooga & St. Louis Ry. mines in Tennessee and Alabama found to be unreasonable and rate of 90c. prescribed.

3—Complaint as to unreasonableness of $1 rate to Nashville on coal from Illinois Central western Kentucky mines not sustained.

4—The value of ton, car, and train mileage statistics in fixing rates discussed.

5—The Louisville & Nashville and the Nashville, Chattanooga & St. Louis interswitch all traffic, including coal, at Nashville. They refuse to switch coal to and from the Tennessee Central, which road retaliates by refusing to switch coal to or from the rails of either of the other two. Upon complaint;

Held, That the practice of all three roads is unreasonable, and further, that of the Louisville & Nashville and Nashville, Chattanooga & St. Louis is unjustly discriminatory. Discrimination required to be removed and reasonable practice prescribed.

6—"Terminals are either open or they are not" and a carrier may not exercise an arbitrary discretion, based upon a strained construction of the proviso of section 3, in saying for what roads and for what traffic it will open its terminals and for what other roads and traffic it will decline so to do.

I. C. C. Nos. 5650 5650, (Sub.—No. 1), 5650 (Sub.—No. 2) —Wisconsin Coal Co. (5650); Elmore Benjamin Coal Co. (5650 [Sub.—No. 1]); Callaway Fuel Co. (5650 [Sub.—No. 2]) vs. Pere Marquette R.R. Co. et al.

Complainants contend that they are entitled to free reconsignment of coal at Milwaukee and ask reparation on account of damage suffered as the result of alleged unjustifiable holding of cars at Ludington, including reconsignment and demurrage charges paid on cars detained, as well as tort damages. The complaint also embraces a charge of discrimination, and further alleges that the new tariff, effective Feb. 9, 1913, is unreasonable because of its failure to provide for reconsignment at Milwaukee: **Held:**

1. Complainants were not entitled to free reconsignment at Milwaukee under the tariff of Oct. 2, 1912, but were entitled to reconsignment at a charge of $2 per car. The detention of cars at Ludington was unjustifiable and demurrage charges were improperly assessed and must be refunded.

2. With respect to cars which arrived at Ludington before the receipt of passing notice and proper time for giving disposition orders, the charges paid were improperly assessed and should be refunded. There is no evidence upon which to measure damages as to cars on which the notice was sufficient. Damage regarding these lies in the difference between the value of the reconsignment service at Milwaukee and at Ludington. No damages were proved as the result of granting reconsignment to complainants' competitors and denial of the service to complainants.

3. The Commision's jurisdiction to award tort or general damages, as distinguished from rate damages, discussed in Jaynes v. P. R.R. Co., 17 I. C. C., 361, and in Hillsdale Coal & Coke Co. v. P. R.R. Co., 23 I. C., 186. In the present case there should be no award for damages of this nature. This conclusion rests on the general principle of the law of torts that one who suffers a tort damage must use due diligenec to minimize or avoid his loss.

4. The Commission has power, in its discretion, to require the establishment of reconsignment and diversion on the basis of the through rate from the point of origin to new destination, with a fair charge for the extra services performed.

5. A carrier may, as a matter of convenience, when its terminal tracks are congested, hold cars at some point short of destination, provided such a course involves no disadvantage to the public.

6. Tariff provision with regard to the giving of passing notice at Toledo should be made. If after the receipt of such notice shippers fail to give disposition orders before the cars reach Milwaukee, they shall be charged for the service $2 per car; otherwise the service is to be free.

7. The power of Congress to regulate interstate commerce is not hampered by contracts made by individuals, L. & N. R.R. Co., v. Mottley, 219 U. S., 467. A corporation cannot disable itself by contract from the performance of public duties and thereby make public accommodation or convenience subservient to its private interests. Gibbs v. Consolidated Gas Co., of Baltimore, 130 U. S., 398.

8. The question of detention is one that must be worked out by itself, and the advantages of reconsignment cannot be thrown away in order to avoid abuses that can be remedied in other ways.

FOREIGN MARKETS

GREAT BRITAIN

Jan. 2—Owing to holiday influences, inactive conditions are in evidence. Approximate quotations as follow:

Best Welsh steam	$4.80@4.92	Best Monmouthshires	$4.26@4.3
Best seconds	4.56@4.68	Seconds	4.02@4.14
Seconds	4.44@4.56	Best Cardiff smalls	2.64@2.78
Best dry coals	4.56@4.68	Seconds	2.52@2.64

The prices for Cardiff coal are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both net, exclusive of wharfage, and for cash in 30 days.

BELGIUM

Exports and imports into Belgium for the first nine months of 1912 and 1913 were as follows:

	Imports		Exports	
	1912	1913	1912	1913
Coal	6,689,148	5,954,292	3,713,154	3,741,741
Coke	851,911	691,920	813,345	738,589
Briquettes	355,394	329,684	470,363	482,579

AUSTRIA

During the first nine months of this year the production of coal in Austria totaled 12,234,247 tons, as against 11,656,476 tons in the corresponding period of 1912; the output of briquettes of coal was 151,179 tons, as against 120,855 tons; and the make of coke 1,909,235 tons, as against 1,716,143 tons. The lignite production during the same period was 20,710,900 tons, as against 19,490,252 tons; and the make of lignite briquettes was 175,502 tons, as against 175,256 tons.

FRANCE

Exports and imports into France for the first seven months of 1913 and 1912 were as follows:

	Imports		Exports	
	1912	1913	1912	1913
Coal	8,713,200	10,777,100	1,206,397	779,428
Coke	1,550,900	1,911,100	104,307	132,736
Briquettes	632,300	633,900	121,192	120,299

The "Daily Consular and Trade Reports" says regarding the situation in Southern France:

The production of coal in the departments of Gard, Bouches-du-Rhone, Basses-Alpes, and Hautes-Alpes amounted to 2,832,257 metric tons of 2204.6 pounds each in 1912, as compared with 2,723,915 metric tons in 1911. In view of the insufficiency and the poor quality of the native coal supply, large quantities are imported. During 1912 1,470,158 metric tons of coal, 21,036 metric tons of coke, and 62,030 metric tons of patent fuel were imported, while 702,237 metric tons of coal, 560 metric tons of coke, and 99,578 metric tons of patent fuel were exported. Of the imports, 17,423 metric tons of coal and 15,911 tons of coke came from the United States.

In this connection the following article, which appeared in the "Liverpool Journal of Commerce," of October 10, is of interest:

The freight rate from the United States to Marseille was about 17 shilling 6 pence ($4.26) last year. The freight rate paid last September was 13 shillings ($3.16). This sharp drop in freight rates is a point in the American coal exporter's favor, and as there seems a probability of freight rates dropping still further in the near future, it is anticipated that an increased business in America's foreign coal export trade will be shown.

No. 12,258. Coaling Plants and Sand Houses—The American consulate general at Ottawa, Canada, reports that the Commissioners of the Transcontinental Railway at Ottawa have advertised for tenders, to be received until January 7, for the construction of six 200-ton mechanical coaling plants with sand houses complete, to be erected at the following points on the line of the railway: Monk, Bridge, Fitzpatrick, Parent, Doucet and O'Brien, all in the Province of Quebec. Plans may be seen and forms of tender and specifications obtained at the office of the mechanical engineer at Ottawa.

COAL SECURITIES

*For the full year 1913. †Sale involving less than 100 shares.

DIVIDENDS

Burns Brothers—Regular quarterly dividend No. 2 on the common of 1¼%, payable Feb. 15 to holders of record Jan. 31, and regular quarterly No. 4 on the preferred of 1¾%, payable Feb. 2 to holders of record, Jan. 15.

New River Co.—Regarding the proposed sale of this company to a British Syndicate, it is stated that the property is optioned at $90 per share of preferred stock with accrued dividends of $30 per share and $5 per share of common. When this stock was issued, a decade ago, two shares of common were given as a bonus with each share of preferred, so that according to the terms of sale, stockholders still retaining all their original holdings will realize $130 per share on their stock.

St. Louis Rocky Mountain & Pacific Co.—This company is said to enjoy the distinction of having the largest coal tract under private ownership in the United States. The company has 13 mines in operation, and has a gross capacity of 10,000 tons daily. Dividends of 5% per annum are paid on the $1,000,000 outstanding preferred stock. The balance sheet to June 30, 1913, showed current assets to be practically double the liabilities.

Canadian Coal & Coke Co.—Fully three-fourths of the authorized issue of $1,000,000 notes of this company have been sold, and the $500,000 advance from American bankers who were handling this arrangement, has already been made. The money received will wipe out the present indebtedness of the company and provide about $350,000 for completion of new development work. It is expected that the present average capacity of 1500 tons a day will be increased to 4000 tons when this new work is completed.

Philadelphia & Reading Coal & Iron Co.—According to a statement of this company, filed with the Massachusetts secretary of state, its coal lands are being depreciated at the rate of $500,000 per annum. Thus the assets show the coal lands to be valued at $49,403,659 in 1912, and $48,905,221 in 1913. The total assets of the company in 1913 are placed at $88,301,880.

Westinghouse Motors For Moderate Sized Hoists

While manufacturing the electrical apparatus for the largest mine hoist installation ever undertaken in the United States, the Westinghouse Electric and Manufacturing Company has devoted very careful attention to the design of motors for moderate sized hoists.

No attempt is made to take motors designed for some other purpose and adapt them to mine conditions. **They are hoist motors and are especially designed in every respect for this service.**

These motors have unusually heavy pulling power for their horsepower rating. The revolving part is small in diameter to permit quick stops and reversals. Low power consumption insures economical operation.

They are particularly designed to allow ease of inspection and dismantling, if necessary. All coils are form wound and placed in open slots, making repairs, in case of accident, as simple as possible.

Our nearest office will be pleased to furnish full information about Westinghouse Mine Hoist Motors upon request.

VOLUME 5 JANUARY 24, 1914 NUMBER 4

CONTENTS

WITH PRINCIPAL ARTICLES SUMMARIZED

*Illustrated Article

FOREWORD: *Page* 151

Outlines the policy of "Coal Age," stating in brief that the paper is an independent forum for the discussion of mining subjects by all responsible men. COAL AGE, Vol. 5.

*AMERICAN COAL MINING AT 80 DEG. NORTH: *Pages* 152-156

Describes the most northerly mining operation in the world. The miners are paid from $1.35 to $1.90 per day; living expenses average about 41c. per day. Even in midsummer, the temperature rises but little above the freezing mark. C. A. Tupper. COAL AGE, Vol. 5.

*THE SYSTEM OF MINING IN THE POCAHONTAS REGION: *Pages* 156-159

The breakline, or line of fracture, should be kept straight and should not exceed 2400 ft. in length. In order that the pillar-slices may all be exactly of the same size, the crosscuts are laid out methodically, so as to come where pockets would normally be driven in retreating with the pillar. Careful work in new mines results in a recovery of 95 per cent. of the coal. W. H. Grady. COAL AGE, Vol. 5.

*CEMENTATION IN SHAFT SINKING: *Pages* 160-162

A description of methods employed, particularly in the north of France, to effectually exclude water from shafts both during sinking and subsequently. COAL AGE, Vol. 5.

*PORTABLE STEEL LADDER: *Page* 162

NOTES ON THE PREVENTION OF EXPLOSIONS IN COAL MINES: *Pages* 163-165

The paper gathers together a number of the most important facts relating to explosions, most of which have appeared but may have been overlooked by readers. Noteworthy remarks are that rock dust is proved to be of value and should be used, and that an explosion can as readily originate in stagnant as in moving air, except perhaps where several shots are fired following each other. In that case the speed of the current may keep the dust in suspension and so make it readily susceptible to inflammation. Geo. S. Rice. COAL AGE, Vol. 5

EXAMINATION QUESTIONS WITH ANSWERS: *Page* 181

COAL AND COKE NEWS: *Pages* 182-185

*ROCK CASTLE MINE EXPLOSION: *Pages* 165-166

An explosion of gas at the Rock Castle mine, located at a town of the same name near Abernant, Ala., killed 12 men out of 90 in the mine. The explosion was quite local. Four men may have been overcome by afterdamp. COAL AGE, Vol. 5.

AN ANALYSIS OF THE OHIO MINING COMMISSION'S REPORT: *Pages* 167-170

The gradual leaning toward paternalism, on the part of both state and federal governments, is becoming more and more marked. The investigation of the Ohio legislature is the most important step that has been made in this direction, so far as concerns the coal industry. The changes proposed are of such a radical nature and will indubitably be so far-reaching in their effect on legislation in other states that coal engineers in all parts of the country are closely following the progress of the movement. A. T. Shurick. COAL AGE, Vol. 5.

EDITORIALS: *Pages* 171-172

Seismic Disturbance in Its Relation to the Flow of Gas into Mines—Once More: A Criticism of the Coal-Land Policy of the U. S. Geological Survey—Explosibility of Coal Dust.

GEORGE OTIS SMITH REPLIES TO EDITORIAL CRITICISM: *Pages* 173-175

The Geological Survey's reports on coal sales, while probably not absolutely in agreement with those of the Land Office, were compiled with full intent to obtain correct results. The statement that the increase in the price of public coal land has reduced production and raised the price of coal in the West is disproved by statistics. COAL AGE, Vol. 5.

Sanity versus the Bearded Lady

The Weekly Ad-Talk Page

We have had a good deal to say in this department about the *sanity* of present-day advertising writing as compared with the stuff that some of the old-timers were wont to foist on an open-mouthed, pop-eyed public.

Once in a while, though, some reincarnated spirit of the original Barnum is loosened upon the world and straightway rushes to its natural channel—printers' ink.

And this is the sort of "break" it delights in:

"Lend Here a Patient Hearing to the Unfolding of a Bargain Story That Will Go Resounding Down the Corridors of Time as the Most Sensational and Attractive Ever Provided the Purchasing Public—

"Pants—Regular Value, $2.50—$1.25.

"Don't Overlook this Store on the Pants Question."

All that mass of words, covering six columns of newspaper space, about a pair of pants.

Doesn't that conjure up visions of the Tattooed Man, who never wears pants on exhibition, and the Bearded Lady, who always wears them when the show is over?

We have seen pants which look as though they might have resounded down several corridors of time. But they are not the kind of pants we choose to encase our shapely nether limbs in.

Rather are they the kind that we carefully avoid, lest their wearer make a touch for a new pair.

We have seen pants that one could buy for $1.25 a pair, but nothing could induce us to believe that they were worth $1.26, much less $2.50.

The quoted advertisement is fundamentally wrong in two points—it tells nothing about the advertised article and it leads the reader to infer that the concern is of a philanthropic nature—or is lying.

And, since we know that businesses exist on *profits*, we are prone to call them liars and shop at less superlative places.

Let us confine our exaggeration to circus advertising. None of us object to being beguiled into spending a dime for the side show. The "magnificent, marvelous, munificent, mind-maddening Albino Beauty" may be Maggie Hennessy, the waitress at Hyde's Hotel, done up in a frizzy wig—we don't care particularly. It's all in the day's fun.

But when we come down to the business side of things, let us cut out the Bombast, the Bunk and the Piffle. Let us have our advertisements clean-cut, informative, convincing and truthful.

We have a story to tell—tell it straight, tell it simply, tell it sincerely.

Then confidence is promoted and the shyster dethroned.

We believe that every advertiser in this paper makes a consistent effort to adhere to the straight line in writing his advertisements.

Hence, we know that they are full of *information*—dependable, instructive information.

The salesmen who call on you, the Selling Section of Coal Age—here are two wonderfully rich mines of engineering knowledge. The pay streak runs wide and deep. Work it for all it's worth.

COAL AGE

Vol. 5 NEW YORK, JANUARY 24, 1914 No. 4

The nature of some of our recent correspondence causes us to use this page to clear up a point or two. It concerns the policy of Coal Age.

There has never been the slightest deviation from a settled editorial aim since the birth of the paper. One word covers our entire plan of procedure—Justice—to all, from miner to owner; at the same time not forgetting the rights of the fuel consumer, who, in the final analysis, is a most important party in our industry's struggle for commercial success.

In line with this idea, we hold that the pages of Coal Age are open to every responsible person who has any interest, directly or indirectly, in the production of coal.

We insist that the paper itself, its owners and editors, be held responsible only for their editorial views. We are opposed to the establishment of a rigorous censorship to pass on the acceptability of matter submitted, only reserving the right to determine that articles and letters sent us for publication are sensible and truthful.

The ideas of the contributors need not conform to the beliefs of the editors, any more than they must coincide with the views of other individuals in the industry. We have published innumerable articles by responsible men, whose statements were opposed to our own conception of the subject in hand.

If you read a biography in the Who's Who columns of Coal Age that covers the life and work of some fellow you dislike, don't hold a grudge against the paper. Maybe, in some ways, we don't like him any better than you do.

Or, if John Henry, superintendent of the "Snow White" mine, expresses views on the liquor problem, the labor question, miners' education, or ventilation, which do not agree with your own opinions, please remember that John Henry is no kin of ours, and we are not responsible for his ideas. Lock yourself in a sound-proof room and cuss him to your heart's content, but refrain from directing your remarks at us.

The coal industry is a business that has nothing to hide. It will profit by having the confidence of the entire population. A journal devoted entirely to the interests of the operators, or one printed solely for the miners, must needs be prejudiced, and such a paper will have small influence with the outsider when its voice is raised in time of real distress.

Nor can a journal conducted in the interests of one class in any business observe and obey the great truth that whatever course of action will benefit the whole people of the United States, will eventually benefit all those who gain their livelihood in any one of our great basic industries.

We prefer the solid approval of a few to the empty praise of many. As for criticism, it is the sure sign of accomplishment. The proof of justice does not always lie in the voice of the majority. The paper that buys popularity at the sacrifice of honor and truth pays too dear a price.

Surely, now, our position is plain. Coal Age is an open forum where every responsible coal man may express his honest opinion. If you fail to refute a statement that seems in error when the privilege is yours, certainly you should not strike from ambush at the fellow who stands in the open and invites your attack.

This paper has doubled the effectiveness of its educational campaign through its course of independent action. No effort has been made to create a masterpiece of literary art. We want to be correct; we have been human, and we intend always to be fair. We aim to do, not what we may, but what we ought, and we shall never plead a cause where our pen will be confuted by our conscience.

American Coal Mining at 80 Degrees North

By C. A. Tupper*

SYNOPSIS—Describes the most northerly mining operation in the world. The miners are paid from $1.35 to $1.90 per day. Living expenses average about 41c. per day. Even in midsummer, the temperature rises but little above the freezing mark.

Recent agitation on the part of English, Norwegian and Russian interests for an international commission to fix the status of property rights in Spitzbergen and provide for some governmental regulation of its affairs, calls the attention of the mining public to a district hitherto generally regarded as beyond the bounds of commercial exploitation. There has, for some years past, been much talk of mining in the Arctic regions, including southern Greenland; but, outside of Alaska and the Scandinavian peninsula, where conditions are comparatively favorable, it has remained for an American concern, known as the Arctic Coal Co., to give the first demonstration of what can be done in a region that is literally ice-bound and only accessible for a small part of the year.

Mouth of Adit with Loading Pockets Below

Coal Pockets Were Constructed from Hillside Stone

Spitzbergen, the "No-Man's-Land," which does not fly the flag of any country and, until quite recently, was considered unworthy of notice, is an archipelago lying between 76 and 80 deg. north latitude and due north of Norway, or about midway from Greenland to Nova Zembla. It comprises the five large islands of West Spitzbergen or New Friesland, Northeast Land, Edge Island, Barents Island and Prince Charles Foreland, as well as the Wiche and many other small islands. The chief island of the group, West Spitzbergen, which has an area of 15,200 square miles, is shaped like a wedge pointed south and deeply indented on the west and north by long branching fjords, one of which is known as Advent Bay. Here, in 1900, coal began to be worked, for sale to whaling steamers, a seam 10 ft. thick being found below 40 ft. of fossil ice and 20 ft. of limestone.

The backbone of the island consists of a mass of pre-Devonian granites, gneisses and schists. Resting upon these there is a succession of sedimentary rocks, lying nearly horizontal, among which the Carboniferous period is well represented, and the developments at Advent Bay may be considered as only the beginning of similar operations in the future.

Coal Sells for about $5 per Ton

The coal found in Spitzbergen is of good quality. It averages, for the deposit mentioned, not more than 2 per cent. of red ash and is free from slate, burning freely in an open grate fire. The prices obtained for the coal are good. At last reports it was bringing 19 to 20 kroner in Trondhjem or Narvik, on the Norwegian coast, equivalent to $5.13 to $5.40 per ton, and for direct sale to the whalers entering Advent Bay the price charged was 14 kroner, or $3.78 per ton. These amounts, however, are moderate in comparison with the prices heretofore asked for English coal in the Arctic regions. At Hammerfest, for example, a ton of the latter has seldom been obtainable at less than 26 kroner, or $7.02.

The Arctic Coal Co., whose headquarters are in Boston, Mass., has staked out at Advent Bay a coal field nearly four miles long. Exploration with steamers and landing parties also resulted in the discovery of a good coal bed in Saxon Bay, at an elevation of about 400 ft. above sea level and another at Cape Bojan. The latter is of excellent quality, but the shore has a heavy surf which will make loading to vessels difficult. At Green Harbor the company has taken over an existing property, formerly used as a spasmodic source of supply by whalers, who maintain a station there for trying out blubber, and this yields a good, hard steam coal which can be readily recovered and transported to vessels by some such method as that described below. Thus the prospects for more extended operations in the future are excellent.

Coal from the present mine at Advent Bay, where the operations in general are along the lines of modern colliery practice, is brought to the surface through an adit,

*Consulting engineer, Milwaukee, Wis.

the mouth of which lies about 600 ft. above sea level and at a distance of fully 4300 ft. from the nearest point where vessels can be moored. The primary condition was the rapid and, so far as possible, automatic loading of the ships after arrival, in order that the maximum number of round trips might be made during the short summer months. The sea around the island is shallow and ice readily accumulates on its shores, with great glaciers pushing down from the mountainous interior. Although these glaciers do not give rise to icebergs as huge as those of Greenland, the smaller bergs and the pack ice are thick enough to prevent access to Advent Bay except for a relatively brief period, and even this would be hazardous except for the warm drift from the Atlantic, which tends to moderate the climate of Spitzbergen and leave an open passage for vessels to approach the coast in summer.

Spitzbergen Has No Native Population

Another requisite, under these conditions, was to concentrate labor upon actual mining and to avoid the use of many hands for anything connected with conveying the coal from the mouth of the mine and loading it upon steamers. Spitzbergen has no native or otherwise permanent population, and every workman has to be brought from the mainland of Europe at considerable expense. This consideration, therefore, eliminated the project first proposed, of running a gravity road to the shore, dumping to a storage plant there and conveying the coal in lighters to ships lying at anchor in deep water outside the surf, even apart from the slow loading which this would involve. It was practicable but not very profitable.

The logical solution was an aërial tramway from the mouth of the adit to a ship-loading station at the sea.

In the accompanying reproductions of photographs, the system constructed is clearly illustrated. As the coal from the mine reaches the adit mouth, it is dumped to a storage plant built on the hillside in the form of a silo, which is provided with chutes for the automatic loading of the buckets attached to the ropeway carriages. Here, during the loading of a ship, only two workmen are required, one for placing the empty buckets in position for filling and the other for operating the bin gates. Arriving in the ship-loading station at sea, the buckets are tripped and automatically dumped to a hopper, when they are discharged into one of the holds of the vessel through an adjustable telescopic spout.

At this point two men also suffice, the duty of the one being to guide the carriages around the return loop and of the second to see that the loading spout is in proper position. As the loads are small and follow each other in quick succession, the amount of labor involved on the vessel itself in properly distributing the cargo is slight, and the crew of the ship can readily take care of both this and the work above referred to, including that at the adit mouth if required.

As soon as the vessel is loaded fore and aft, a bell signal is given to the loading plant at the mouth of the mine, so that the operation of the aërial line will be suspended until the ship can take up a new position. This is easily effected by ropes and windlass, and the telescopic spout is shifted by means of a small slewing crane. By the system described a steamer can be loaded in 6 to 12 hours, according to its carrying capacity.

The saving in time which it effects is graphically shown on the other side of the bay where an English corporation has opened what are known as the Fangen Mines. There the coal is brought down a distance of only 650 ft., but by means of an ordinary incline, and is then dumped into lighters, which carry it through the surf to the steamers anchored in deep water, where it must be handled by cranes and manual labor. With these means it takes several days for even the smaller loads.

In the construction and operation of the aërial line, which was designed and built by Adolf Bleichert & Co., of London and Leipsic, there are many features of suggestive value for similar conditions elsewhere.

The Tramway Is Self-Operating

The longitudinal profile shows a line with heavy down grade from the mouth of the adit to the loading station at the sea, which is built on pile work. Owing to the fall, the line, of course, requires no driving mechanism. On the contrary, an excess of power is developed which must be braked. For this purpose a brake regulator from the firm J. Schrieder, Saeckingen-am-Rhein, Germany, is installed in the mine loading plant. This consists essentially of a rotary pump with a balanced sliding throttle

Bringing in Tramway Material from Sea, over Pack Ice

valve, which is driven by a belt from the countershaft. The pump draws in oil or soap water from a reservoir in the box foundation and forces it back into the latter through the apertures of the adjusting slide. The latter is actuated by a centrifugal governor on the driving shaft of the tramway. As soon as the number of revolutions of this shaft reaches a predetermined limit, owing to the excessive loading of the down line, the governor closes the valve proportionately and retards the action of the rotary pump, which thus acts on the shaft as a powerful brake. The position of the regulating mechanism is shown in the illustrations.

The details of loading at the mine are also to be plainly seen from the cuts. At the left-hand upper of one of these the adit mouth will be seen, with a slide leading to the coal pockets at the beginning of the aërial tramway. The coal is here shunted by hand to the various pockets. These pockets terminate in lock chutes, before which the loading track of the tramway is laid. A short rail siding is also provided for any carriers not needed in the operations. The carriages, with their buckets as loaded,

are pushed by hand over the end return loop or over the intermediate switch to the station exit, where they couple automatically to the constantly moving traction rope.

The line has a length of about 4400 ft., runs over 15 timber supports and will carry daily 1000 tons or more, according to the capacity of the ship to be filled.

into vessel chutes. Eventually more coal pockets will be built at the mouth of the mine.

Outside Work Is Suspended during Winter Months

In the erection of the tramway there were great difficulties to be overcome, as a result of the climate and the nature of the country. Unfavorable ice conditions, when

Start of the Aërial Tramway, Showing Miners' Houses in Valley Below

The unloading station at the sea, as revealed by the illustrations, consists primarily of piles driven to bed rock at a considerable depth and carrying a platform on which an end return sheave is fitted. The aërial carriages uncouple automatically on arrival and dump to the hopper, being then pushed around the loop to a point where they again grip the traction rope and are whirled away upward. A narrow gangway connects the station to the shore; but between the last support and the station at sea there is a clear span of over 800 ft. The shore terminus is reinforced by rubbish dumped around the last land support, and this is being extended outward, so that in time the length of span over the water can be decreased if found desirable.

The silo-like storage plant at the mouth of the mine cannot take all the coal mined during the winter, and, aside from what can be conveniently held underground until vessels are loading, a coal dump is provided on the shore by dumping from the open line of the tramway. In order to take coal from this dump during the summer months, a temporary track is run on piles to the ship-loading station, where the cars are tipped by hand

the work was commenced, prevented any approach directly to Advent Bay until the summer season was far advanced, thus necessitating transportation of material many miles over treacherous pack-ice. The ground, which is frozen even in the warmest months, caused further trouble, as all excavations for the supports of the tramway had to be blasted out. Under these conditions, the end of the third summer had arrived before the line was completed. During the winters, operations had to be entirely suspended above ground, although the mine itself continued to be worked.

In the building of the loading station at the mouth of the mine some of the most disheartening obstacles were encountered. The steep incline of the hill was thickly covered with sandstone boulders, like much of the glacial drift of arctic America, and these were cemented by masses of ice. Before blasting for the foundation itself could be commenced, this frozen strata, many feet thick, had to be removed. Then the small rocks were collected, shaped and used as building material, for bringing in brick from Europe would have been expensive; and the resulting structure, although of irregular, unat-

tractive appearance, is much better suited to withstand the rigors of the climate. In using a mortar binder, it was necessary not only to keep this at a proper temperature, but also to heat the rocks themselves. During the warmest period the atmosphere on Spitzbergen rises only slightly above freezing point under the direct rays of the sun, and everything immediately congeals again in the shade. The building material and parts for the tramway were raised over an incline by means of ropes and winches.

The construction of the aërial tramway, in its various details, was of a character to suit the severe climatic conditions as well as the capacity and duty which would be required of such a line in an ordinary colliery district of the United States or Europe. The track cables used are of the "locked-coil" cable type, so named from the fact that the outer wires, which are drawn to shape, interlock one with another. The smooth surface thus obtained results in a uniform distribution of wear which not only lengthens the life of the cable itself, but also of the carriage wheels that run on it. To keep the track cables coated with oil or compound there is a special traveling oiler. This consists of carriage underhung by a receptacle in which there is an oil tank and a small pump. The latter is so connected to the moving wheels of the carriage that it is kept constantly in operation and sends a light spray between them onto the carrying cable.

The traction cable is of equally good quality and strength for the operating requirements. It is made of strands coiled about a hemp core in the usual way, each strand being composed of steel wires. Both are twisted in the same relative direction, which differs from the usual practice. For coating the traction rope there is another ingenious device. This is a U-shaped receptacle containing the compound, which is suspended near the upper terminal sheave. The cable passes first over a small roller in this receptacle, which in revolving slushes it with the coating material, and then between brushes placed a little farther along, which wipe off the drip.

Arrangements for anchoring and applying tension to the cables are in accordance with usual engineering practice for lines of this kind. In tightening the cables, however, chains have not been used, as they are apt to snap in the severe cold of Spitzbergen, but the tension weights are hung by steel-strand cable of special make. All cable lengths are fastened together by a patent coupling originated by the tramway builders.

Each carriage consists of two steel side plates, between which are mounted two cast-steel wheels fitted with phosphor-bronze pins, so designed that, as the upper surfaces become worn, they can be turned underside up. The hanger pins are of machinery steel. In order to provide carriage grips which would adapt themselves to varying cable diameters due to wear, as well as to changes in grade, the carriers were provided with what are known as "Automat" couplings, with underhung grips, which operate automatically. These hold the loads securely in vertical position at any grade and are self-adjusting to variations in cable thickness. For the track or carrying cables, there are also special shoes which prevent springing. For these there have been provided steel hoods, with hinges, that cover the cable on both sides of the shoe or saddle and protect it from undue wear.

Care was taken in the erection to have the terminal

END OF AËRIAL TRAMWAY AND STEAMSHIP PRIOR TO LOADING

rails at the loading and unloading station, as well as the intermediate saddles, exactly in line with the track cables, so that there is no jar or reaction as the loads enter or leave.

The Supporting Towers

The supporting towers are built of logs and roughhewn timbers of Norway pine, and the entire construction is as simple and inexpensive as it could be made, consistent with strength and operating economy. Not only is the plant the most northerly of its kind in the world, but it is also a good example of how mineral deposits inaccessible to transport by ordinary means, *whether on a coast difficult of approach or in badly broken or mountainous country*, can be brought to a stage of profitable development by a simple system of delivery to a loading point.

While abroad not long ago, I saw many aërial tramways, which are far more extensively utilized in Europe and in European colonies than in the United States, Canada or Mexico. The system above described has, however, been introduced to some extent in this country by a company now forming part of the American Steel & Wire Co., the present American licensees. Other successful aërial systems are those of the Broderick & Bascom Rope Co., A. Leschen & Sons Rope Co., John A. Roebling's Sons Co., the Painter Tramway Co., Macomber & Whyte, the Riblet Tramway Co. and the Vulcan Iron Works.

It was stated to me, while in northern Europe, that many attempts had been made to get at the mineral riches of Spitzbergen, but that the Arctic Coal Co. was the first to undertake the work on a proper financial basis and with adequate equipment of a permanent character. Operations are divided into two parts, the summer and the winter campaigns. For the former, which lasts from the beginning of June until the middle of September, about 200 men come from Norway to Advent Bay in the company's steamer "Munroe." During the winter months only half the force remains. They work 9¾ hours per day and live in company houses, having quarters for from 8 to 20 men each. These houses are built of heavy boards, fourfold, with thick building paper between all boards; and, with the additional heat insulation provided by the snow and ice on the outside in winter, the men are kept very warm and comfortable.

Wages paid are 6 to 7 kroner for miners and other skilled laborers, 5 kroner for muckers, trammers and laborers generally, and higher-grade employees in proportion. From these amounts, 1½ kroner per day is deducted for board and lodging; so that, with good behavior, each man has at the end of the season an ample surplus to carry back to Norway. Except for whalers caught in the ice, the employees of the Arctic Coal Co. were the first to winter in Spitzbergen, and they may, therefore, be regarded as pioneers in the settlement and systematic development of the islands.

The System of Mining in the Pocahontas Region

By W. H. Grady*

SYNOPSIS—The breakline or line of fracture should be kept straight and should not exceed 2400 ft. in length. In order that the pillar-slices may all be exactly of the same size, the crosscuts are laid out methodically so as to come where pockets would normally be driven in retreating with the pillar. Careful work in new mines results in a recovery of 95 per cent. of the coal.

I have had occasion to examine mines which produced during 1912 an aggregate of about 15,000,000 tons of coal. The conditions in which this coal was found admitted of the use of all the different methods of opening a property and the seams and overlying and underlying strata varied in their character so as to give, in some cases, the best and in others the most unfavorable conditions. Though the observations were all made east of the Ohio and Mississippi Rivers, the principles I shall advocate are applicable anywhere to room-and-pillar work.

It is a bad practice to drive up a room and allow the pillars to stand in the expectation of drawing them later. A better method is to start to "stump off" the pillars as soon as the room is completed by cutting across the rib as at *A*, in Fig. 1. The track should be laid so that cars can be placed conveniently for loading out both the coal in the cut and also that mined when the stump is drawn back.

Driving "Pockets" in Pillars

In this method, the miner is always protected by solid coal and the losses are reduced to a minimum. Room No. 6 shows the pillar and the heading stumps completely removed; room No. 5, a pocket just starting in; room No. 4, a pocket finished and a stump partly drawn back. Room No. 3 shows the pocket finished and work just starting on the stump; room No. 2 shows the pocket being driven, followed by a second pocket, which is only extended as far as a man can conveniently load the coal without a track turn, in order to avoid the necessity for frogs and switch points. Room No. 1 shows the pocket just starting.

The width of this pocket and the thickness of the stump depend largely on the nature of the roof and the mine equipment. With poor roof, which falls unexpectedly or within a few hours after the removal of the coal, the thickness of the stump should be such that a miner can reach all the coal safely and easily without venturing too far beyond the rib line of the pocket. If

Note—Second part of article entitled "Some Details of Mining Methods with Special Reference to the Maximum of Recovery," read before the West Virginia Coal Mining Institute, Dec. 9, 1913. Two of the illustratrons in this article appeared in a description of "Mining in the Pocahontas Field," by Audley H. Stow, Vol. 3, pp. 596 and 597, and we owe an apology to our readers for reproducing them. Because they are necessary to the text, which is in every way original and because they were received with approval at a leading institute and further because the method described is so worthy of general adoption, we venture to repeat them in this issue.

the roof is good and does not fall soon after the removal of the stump, the thickness of the small pillar may be increased and the number of track turns required per pillar may be reduced.

In the application of mining machines to the robbing of pillars, the distance between centers of pockets should be such that the thickness of stump left will form, under bad roof, one machine cut, or under good roof, two cuts of the machine.

How Slate Is Kept Out of Coal

The more common practice where the roof falls soon after the extraction of the stump, is to leave a small shell of coal to protect the miner from the gob and also to prevent him from loading fine slate into the car of coal. This results in a loss of coal that can be avoided at an expense for timber, which, under ordinary circumstances, is less than the value of that coal.

A practice which has been advocated and has proven

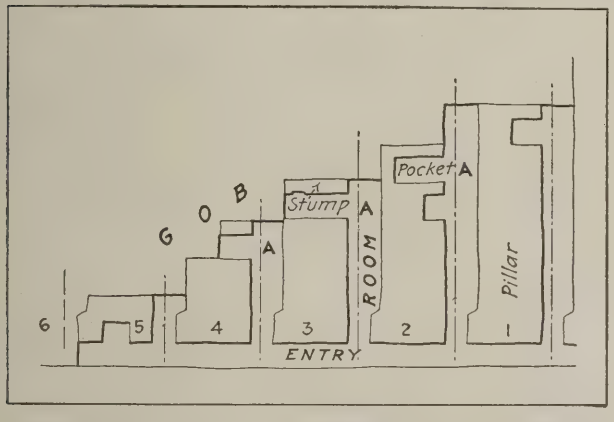

Fig. 1. The Pillars Are Repeatedly Split in Their Shortest Direction as at *A*, and the Narrow Stumps Removed on the Retreat

successful, is to place a row of props on the lower rib of the pocket, before the removal of the pillar stump has begun. When the next pocket to the outby is driven, it will be found that practically the entire stump may be loaded out without any admixture of gob and a greater percentage of lump coal will be obtained. This precautionary row of timbers is especially desirable where machines are used on the pillars.

I have noted that the roof over a robbing line exceeding 2400 ft. in length, sometimes begins to sag in the middle and renders the removal of the pillars in that immediate section difficult.

How the Fracture Line Is Kept Straight and the Recovery at a Maximum

The breakline should be kept as uniform as possible at all times. A method in practical every-day use, which is to be recommended is as shown in Fig. 2.

The engineers, as they take their monthly measurements, mark the pocket centers on the robbing rib of the room, and the foremen are required to drive their crosscuts on the line of a pocket as at *A*. The object in keeping the break line uniform is to insure against pillars extending back into the gob and acting as a fulcrum, or the knife-edge of a scale beam, upon which the roof teeters. This almost invariably causes additional timber expense and sometimes losses of coal, both of which could have been avoided had the break line been kept uniform.

Plan Suited to Needs in Development

Fig. 4 is the general plan of mining advocated by the Pocahontas Coal & Coke Co. The essential features of the plan of mining are: Provisions for tonnage during the development period; provisions for meeting the market demand; large barrier pillars insuring against squeezes and rendering impossible the destruction of coal over an extended area; four-entry system for all extensive main entries, using two as intakes and two as returns with breakthroughs between only at the points where the cross-entries turn off, rendering unnecessary the building of expensive masonry brattices every 80 ft. and insuring the maximum quantity of air for ventilation at a minimum cost for brattices and ventilating power; cross-entries with narrow chain pillars permitting the rapid advance of the entry.

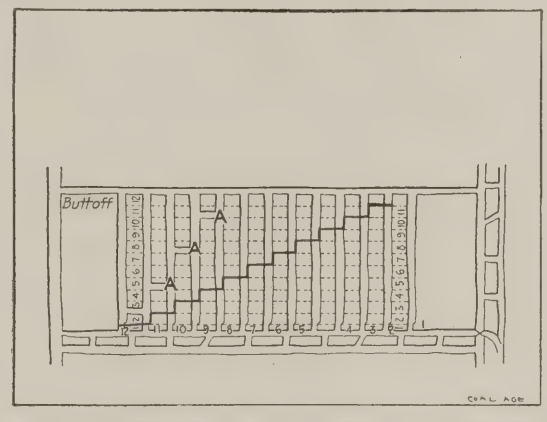

Fig. 2. Crosscuts Are Located at Carefully Chosen Distances as at *A*, so as Not to Interfere with Lifts from Pillar

In general all robbing must be done retreating with rooms driven after the entry is nearing completion, insuring against slate falls and rendering possible the extraction of all of the coal in one operation, thus combining first development and robbing.

Variations in Plan

The depth and number of rooms on an entry vary greatly at different mines, depending on local conditions of the seam; whether the haulage is by mule or gathering motor, whether the undercutting is performed by pick or machine, and not infrequently on the personal equation of the mine executive, for sometimes the manager of a plant will contend that he obtains the best results when he drives 25 rooms 500 ft. deep to the entry, and another manager working on an adjoining property under identically the same physical conditions and with the same type of equipment, not 1000 ft. away, will say that he gets the best results when his rooms do not exceed 300 ft. in depth and when there are only 15 rooms to the entry. The better policy is to encourage individual initiative and allow freely such modifications in any plan of mining as may be desired, provided that the modified plan embodies all the principles of modern methods and sound mining practice.

In the successful operation of any mine some general scheme of mining must be agreed upon, subscribed to by

all parties in any way concerned with the matter, including the land owner, if the property is a leased one. Then no omissions in, additions to, or deviations from that plan of mining should be permitted without the written consent of the lessee and lessor.

RECOVERY OF COAL IN MINES OF POCAHONTAS COAL & COKE CO.

Plant	Thickness of seam in feet	Acres of entry-mined	Acres of rooms mined	Acres of pillars mined	Total acres mined	Total tonnage mined	Tons mined per acre	Theoretical tons per acre	Percentage of recovery	Proportion of seam rejected

The Annual Balance Sheet

After the general plan of mining has been decided and operations begun, its success or failure will depend largely upon the degree of watchfulness exercised. The mine should be accurately surveyed and mapped at least once every 90 days. Frequent inspections should be made of the mine, minute attention being given to the condition of the working faces and the robbing line. At least once a year the theoretical yield of the property should be balanced against the actual tonnage delivered at the tipple. Accurate and complete records should be kept of the number of acres of entries, rooms and pillars driven each year and of both the percentage of recovery per acre and the state of exhaustion of the property.

That the above method of mining will yield the maximum of recovery is testified by the table above, the figures of which are typical of the results obtained by the Pocahontas Coal & Coke Co. in the Pocahontas field, and these, so far as I know, are not excelled anywhere. In this connection it should also be noted that the percentages of recovery are based on the total seam, including the portion rejected.

Recovery Lowered by Slipshod Work of Earlier Years

The lower percentages of recovery in the table result from the fact that in some instances, pillars are now being robbed that have been standing for many years. In the mines of the United States Coal & Coke Co., at and near Gary, W. Va., where all the work has been opened in recent years, the average percentage of recovery per acre since the beginning of operations, has been better than 95 per cent., and of the area mined, over one-third has been final mining. Digressing for the moment, if I may, from the main subject of this paper, I would say that perhaps nowhere is more thought being given to the subject of economical and safe mining than at the mines of the United States Coal & Coke Co. I have visited all the so called "model mines," including those of the anthracite field, for the express purpose of studying them, and it is a pleasure to be able to say that here in West Virginia, at Gary, by the untiring efforts of Edward O'Toole, general superintendent of the above company, a mining organization has been created which, for efficiency, is unsurpassed. Not only are the present methods of mining efficient, but the O'Toole combination, coal cutter, loader and transporting machine bids fair to revolutionize the present method of mining coal for coking purposes. Any one wishing to visit Gary is always welcome and the officers of the company will go to extremes in making your stay instructive and entertaining.

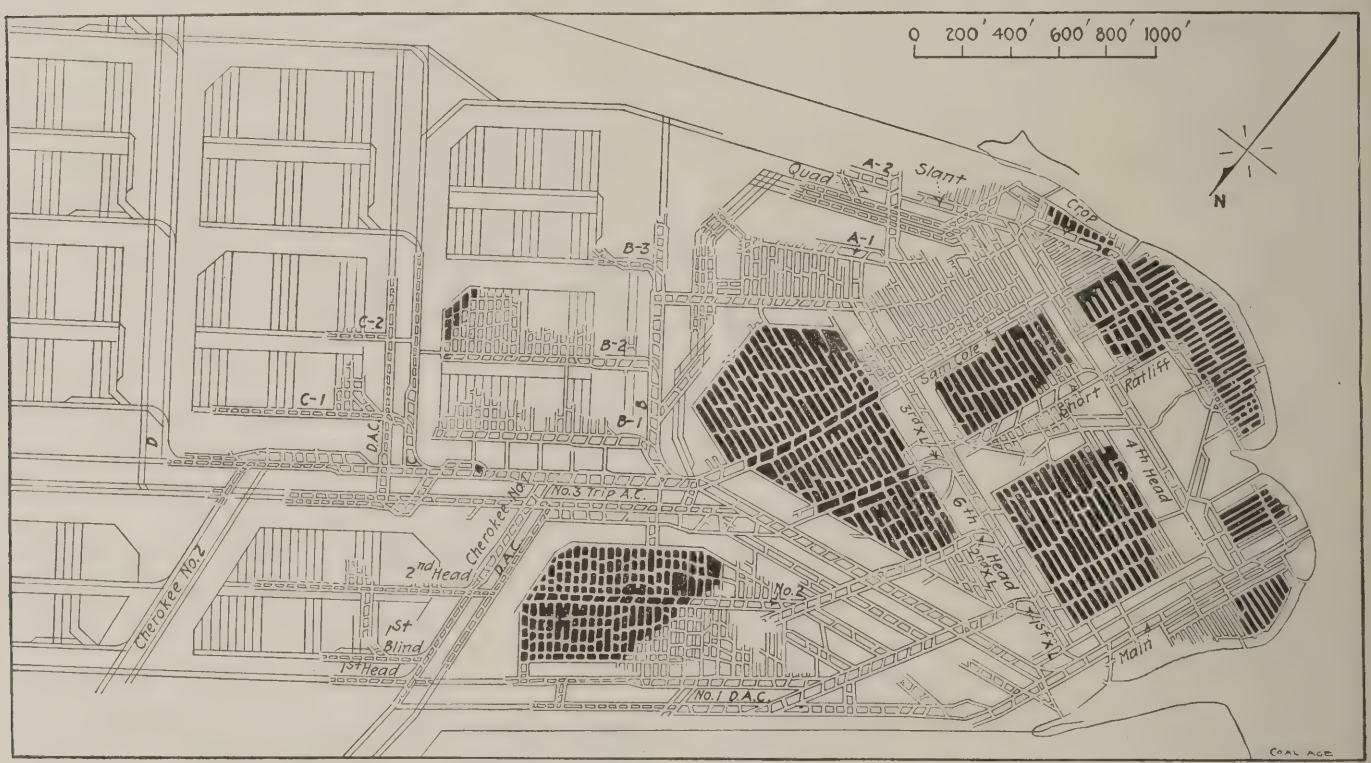

Fig. 3. The Old and New Methods at the Angle Colliery. The Former Are Illustrated by the Detailed Portion on the Right and the Latter in Skeleton Form on the Left

Cheaper Than Wasteful Methods

Returning to the main subject of the paper, I would say that the cost of production of room and entry coal by

this method is the same as in other methods of mining, while pillar coal is produced at less expense than is incurred in other methods.

In addition to the statement quoted all operating companies, I presume, have a statement showing the revenue derived from operations per ton of coal mined based on the net receipts from operations divided by the tonnage. By placing a value, which could be closely approximated, on the recoverable coal lost, and adding it to the net receipts a figure could be obtained showing what revenue would have been derived from the operations had the coal been mined without unnecessary waste. Dividing this by the tonnage a figure could be obtained for the statement which would show the profit that would have been derived per ton produced if the coal in the seam had been worked by the most conservative methods.

Bonding Value of a Well Managed Property

Statements of the above nature have a further value from a financial point of view for if it can be shown to a bonding concern that a property contains, let us say $500,000 worth of coal in the ground, 90 per cent. or more of which will be mined, it is certain that a greater asset value will be placed on the property than would be credited to it if the engineers of the bonding house report that under the methods of mining pursued, only 50 per cent. of the coal in the ground will be mined and the rest irretrievably lost.

In conclusion I desire to express thanks to all those who have in any way contributed to this paper, and especially to Thomas H. Clagett, chief engineer, Pocahontas Coal & Coke Co..; W. A. Phillips, general manager, Ashland Coal & Coke Co.; James Elwood Jones, general manager, Pocahontas Consolidated Collieries Co., Inc., for the use of the maps included in my paper.

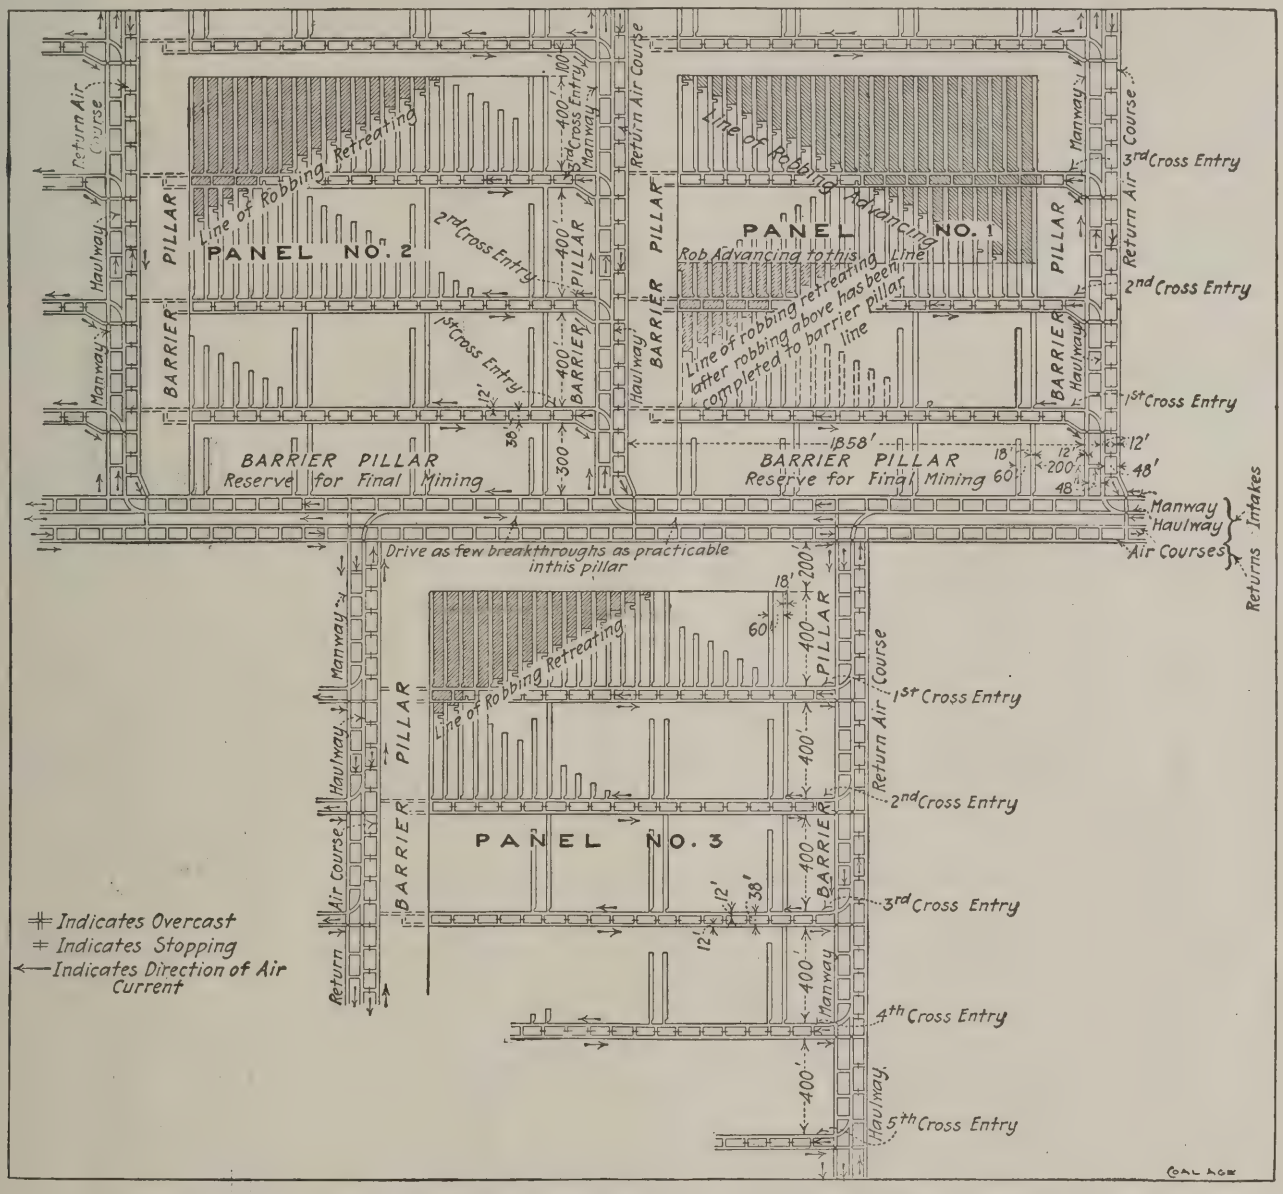

Fig. 4. General Plan of Mine Development of Pocahontas Coal & Coke Co.

A Prosperous Mining College

The short session for mining men at the College of Mines, University of Washington, Seattle, Wash., opened on Jan. 5 with a registration of 44 mining men from 10 states, Alaska, and five foreign countries. The course lasts three months and is arranged in sections for quartz, placer and coal miners.

Cementation in Shaft Sinking

Special Correspondence

SYNOPSIS—A description of methods employed particularly in the north of France to exclude water effectually from shafts both during sinking and subsequently.

Considerable attention has been paid recently to methods involving the use of cement during shaft sinking in cases where the strata would otherwise present difficulties either mechanical or due to the infiltration of water both during sinking operations and subsequently.

At the International Congress at Liége, in 1905, the report of Monsieur Portier showed the excellent results obtained in the north of France by the cementation of water-bearing strata during the sinking of pit shafts.

Since then J. Lombois has described cementation methods of water-bearing territory, adopted by the Compagnie des Mines de Béthune in the bulletin of the Society of Mineral Industries, while later Monsieur Saclier has described in the Annales des Mines de France similar methods adopted by Edouard Agache in the sinking of shafts. These descriptions have called attention to the value of cementation methods, such as are now adopted extensively in France.

In these processes the operations succeed each other somewhat as follows: First, boreholes are sunk of sufficient number and proximity to each other to render the ground impermeable at the completion of the process. Then, thin cement grouting is injected into these holes either simultaneously in all of them or by sections, the third stage is the sinking of the shaft itself.

This method of operation which has been successful in the cretaceous area of the north of France is not necessarily applicable without modifications or extensions to other circumstances which are encountered in sinking operations. It has been found, for example, in the porous ground, such as the sandstone of the Vosges where there are a large number of small crevices that the penetration of the cement would not be sufficient for those pits much over 640 ft. in depth, the time taken by the various operations being too long. With these points in view, advances have been recently made in cementation methods which are worthy of attention.

Where Numerous Fissures Are Met

Suppose that cement grouting is injected through one or more boreholes at a time in a stratum of ground containing numerous fissures. This condition is represented in Fig. 1 where *A* is a fissure of considerable width of opening, *B*, one which, although of considerable capacity, has a narrow neck or mouth to the borehole, *C* and *D* are fine cracks, while *F* is an extreme case of a capillary fissure.

The cement method to be entirely successful must adequately deal with all these types of fissures. It is, however, well known and always evident that all the grouting tends to enter the large openings, such as that at *A*, and during the time that it is penetrating these openings the pressure possible in the boreholes is not high. Furthermore, until considerable pressure is established, the cement will not enter into the more restricted crevices.

When the pressure increases somewhat, the cement is able to make enlargements in constricted fissures, such as *B*, but finally when the pressure has become high, say for example, 10 atmospheres, a considerable proportion of the fine fissures such as *B* and *D*, and also the capillary fissures *F* have become clogged at their entrances, and the cement grouting is unable to penetrate. In other words, during the period of low pressure, the grouting traveling down the boreholes deposits itself to a certain extent upon the walls and sides, with the result that when at last the higher pressure is attained the smaller openings are sealed.

When the duration of injection exceeds two hours from the first introduction of the cement, the inconvenience

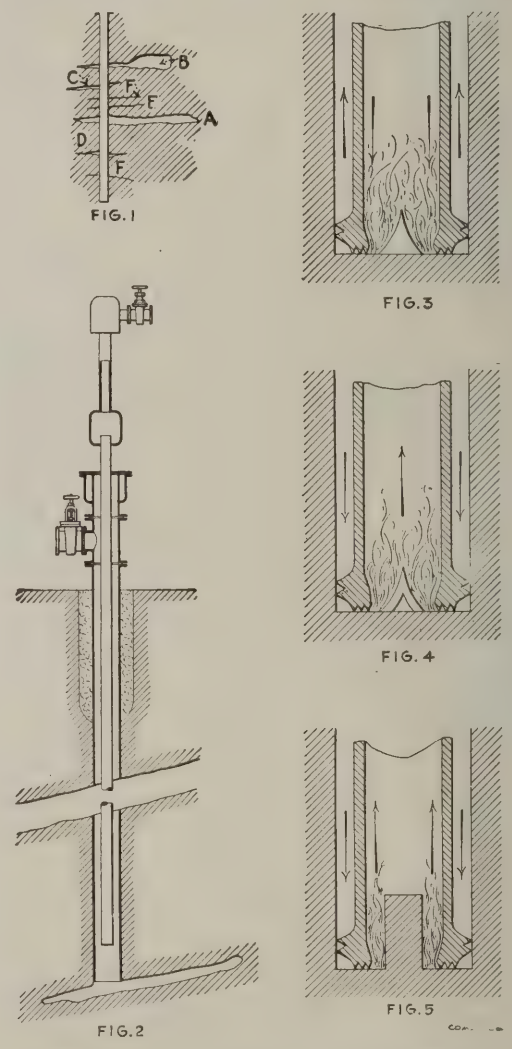

Illustration of Boring and Cementation Conditions

becomes so great that the value of the method is questionable. To the well known fact that the injection of cement should be carried on under the highest pressure, the further statement may be added that this high pressure should be established in the boreholes as rapidly as possible. Otherwise the efficiency of the method will be reduced.

Treat the Fissures Individually

In order to obtain the high pressure quickly, it is essential that the grouting shall not at any one time en-

counter a large number of exits such as a number of fissures in its path. This leads logically, therefore, to the necessity for a method of cementation by which each fissure or small group of fissures is dealt with individually

It is known, of course, that in boring methods employing a current of water, the gage on the in-going pipe always indicates a certain pressure, which depends on the depth of the bore, the diameter of the rod and of the hole, and the volume of water being circulated. As soon as the bit upon the end of the boring-rod encounters a fissure in the earth, this pressure gage indicates a sharp variation, generally a drop. It then becomes advisable to inject into this fissure, cement grouting under a pressure of 10, 15, or even 20 atmospheres.

In order to do this, a certain distinction must be made between methods applicable to small holes or shallow depths and those which have great depths. As soon as

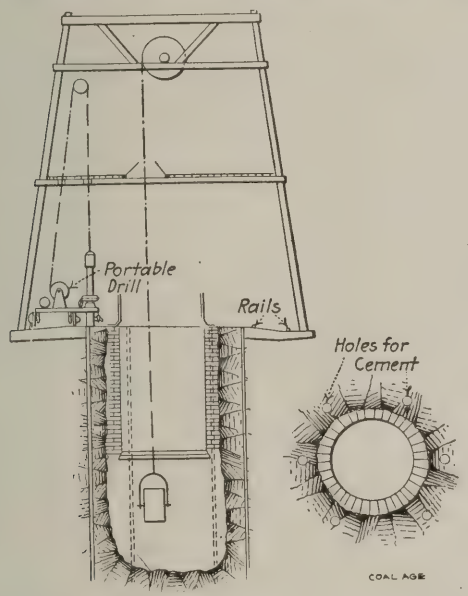

FIG. 6. ARRANGEMENT OF SINKING AND CEMENTATION APPARATUS

the bit touches the fissure indicated by the pressure gage, the rods are withdrawn, the boring apparatus removed to another hole, and there started to work, while in the meantime cement is brought to the first hole and there prepared for injection.

The grouting is forced into the interstices either by pump or compressed air, or by water under pressure as an intermediary. It is necessary also when following the above procedure that the apparatus for boring and cementation be light and transportable. It should be mentioned also that at small depths it is not usually possible to use high pressures, since under these circumstances communication between the fissures and the surface may be established.

THIS METHOD IMPRACTICABLE AT GREAT DEPTHS

If the depth is in excess of approximately 500 ft., this method of working becomes impracticable. In order to withdraw the 500 ft. of boring-rod, about half an hour would be required, and it would not be advantageous to perform this operation frequently. Moreover, a boring 6 in. in diameter, and 500 ft. deep, would have a capacity of 3¼ cu.yd. That is to say, in order to bring direct pressure upon the grout it would be necessary to handle 3¼ cu.yd. of material before the fissure would be placed under pressure.

This method, therefore, is too long. Furthermore, at the close of the operation there would be a considerable amount of cement in the hole. It is advantageous, therefore, in order to convey the cement to its destination in the least possible time to cause it to travel through a tube.

In practice, the tube is the boring-rod itself. The head of these rods and the head of the borehole are both closed by cocks or valves, in order to allow the passage into the boring of water or cement grouting, to control these liquids either as a direct or reversed current or even in both directions at the same time as explained later. Another object is to maintain in the borehole a pressure which can be regulated at will.

The two cocks disposed in this way are characteristic of the boring apparatus invented by J. V. Drejcha. They allow great rapidity in operation.

While it is true that the injection of cement through the boring-rod carries with it the easily seen danger of wedging the rod and the bit in the hole, if, during cementation, these parts are given a slow movement of rotation, this danger is much diminished.

A considerable number of operations carried out in the sandstone of the Vosges Mountains have shown that the earth exerts no elastic pressure upon the cement. That is to say, that the filled fissures do not give back their contents to the borehole when pressure upon the grout is removed.

A case or so to the contrary has, however, occurred, and the phenomenon has been attributed to the fissure being of such wide extent that the grouting under pressure raised the earth. When the pressure was withdrawn, the earth settled back, the cavity lost a certain amount of its volume, and a cement pat was ejected into the boring.

It is evident that in such a case it would be necessary to imprison the pressure in the hole at the close of the injection by closing both cocks, which would make impossible the withdrawal of the boring-rods. Consequently, the injection of cement through the boring-rod is not practicable where fissures have a tendency to return the cement grouting. Neither is this method applicable for a similar reason when the water encountered by the boring is of a spouting nature.

In such cases it becomes necessary to apply the first method as in borings of small depth. Practice shows, however, that in such cases since the volume of cement to be injected is large and the operation important, the relative inconvenience of removing a rod and filling the hole with grout is decreased. On the other hand, in the general case of fissures which do not return the cement, it is possible after the injection to continue boring which is in this way only slightly interrupted by the work of methodical cementation.

THE VARYING DENSITIES OF THE GROUT

As has been stated above, cement injection should be carried out rapidly. Now the density of cement grouting that can be employed may vary in practice from 3 per cent. to 20 per cent., according to the apertures of the fissures encountered. In continuously employing a 3 per cent. grouting, the operation takes an inconveniently long time; but if a grouting of 20 per cent. is uniformly employed, as appears to be the general tendency, one apparently obtains a rapid and efficacious result.

Unfortunately, however, this cement does not penetrate into the small fissures, with the result that, during deep sinking, fissures which have not been closed are likely to be found.

In order to convey a light cement into restricted fissures and a dense cement into open ones, it becomes necessary to conduct a preliminary examination. That is to say, to predetermine the pressure necessary to introduce a certain volume of water per minute into any particular crevice.

Such a measurement involves merely a determination of the constant of the sinking apparatus, taking account of the diameter of the rod and the depth of boring, these measurements, of course, possess only a relative value and indicate with certainty only that in any particular borehole the fissure which has to be cemented is more or less open than those previously treated. From this, however, one can get some kind of idea as to the capacity of the opening.

French engineers, who have given thought to operations of this description, have shown clearly that the dirt produced by the work of boring has a tendency to enter the fissures and prevent the cement from taking due effect. The various methods which have been adopted to execute boring with a current of water or by washing the fissures by pumping are convenient for small depths, but these palliatives unfortunately cannot be applied to depths of over, say 330 ft., since they then become slow, costly and not altogether efficacious.

Reduce the Amount of Dirt

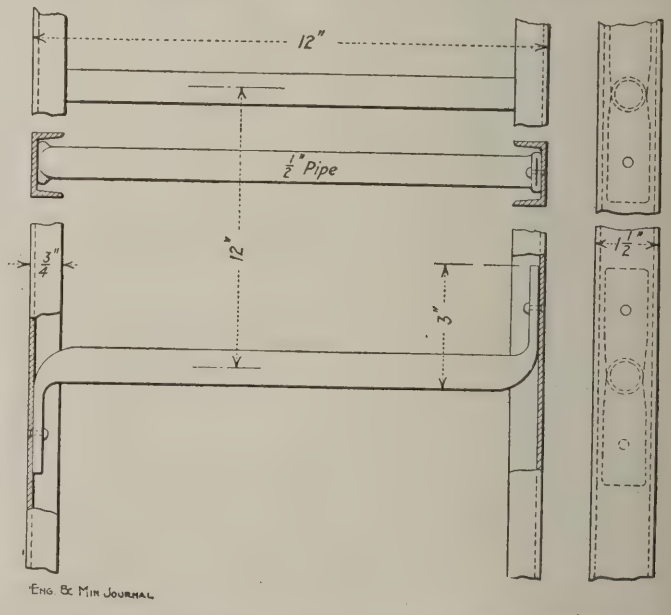
In case of greater depth it becomes necessary to apply other principles. The borings should be made of small diameter in order to obtain as little dirt as possible. They should be made, if practicable, with the crown bit, which gives heavier pieces of material than does either the saw or trepan. The work should be done in a reverse current of water, and the cement injected methodically to each fissure as soon as encountered by the boring tool.

The favorable influence of the reverse current of water is clearly illustrated in Figs. 3, 4 and 5. It will be seen that the current exercises at the bottom of the cutting a suction action, relative of course, while it has a tendency to throw the dirt about. The facility of ascension in the rod is easily observable by the spectator who notices the cuttings coming out of the discharge during the course of work like small projectiles.

Boring contractors know well that a reverse current is dangerous because it produces in the boring falls of material with consequent jamming of the rod. Methodical cementation of fissures or frequently introducing into the borehole, cement under a pressure of 15 to 20 atmosphere, converts a hole which would otherwise have many loose particles along its side ready to fall to the bottom into a veritable tube of compressed concrete, effectually preventing any dislodgment of material.

The Three Essential Features

The three special features of this method of cementation are, therefore, boreholes of small diameters, the use of a reverse current and methodical cementation. These operated together form the characteristics of the method employed by the Société Anonyme de Forges et Enterprises Minières Trefor of Brussels.



Mining organizations which are forced to sink deep shafts have, of course, as a particular object the saving of time. From this point of view, methods which consist of boring a ring of holes and injecting cement through them before beginning to sink a shaft require long periods for great depths.

With methodical cementation on the lines described above, effected by light and transportable apparatus, it is possible, however, to keep the section of the shaft free from boring apparatus, and to actively carry on shaft sinking at the same time. By this means the work of cementation progresses simultaneously at from 45 to 60 ft. in advance of the shaft sinking. The work of the sinkers is, therefore, executed in ground which is practically a monolith.

Fig. 6 shows the arrangement of apparatus for such shaft-sinking methods carried on under the Trefor patent, and needs no explanation. This system is being adopted with considerable success, not only in France and Belgium, but also in Great Britain and other countries.

Portable Steel Ladder

The Penn Iron Mining Co., on the Menominee range, is adopting an all-steel ladder underground and its introduction into coal mines having steep pitches is well worthy of consideration. The following note is taken from the columns of the *Engineering and Mining Journal*. The illustration shows the type used in stopes and manways where the installation is more or less temporary. The ladder is 12 ft. long, 1 ft. wide and weighs a little under 50 lb. The sides are 1¼x¾-in. channels with the flanges inside; the rungs are of ½-in. pipe. The

Light All-Steel Ladder of Pipe and Channel

ends of the pipes are bent at right angles in opposite directions, flattened and riveted to the channels, the rivets being countersunk on the outside. The ladders are of unusually light construction, but are found to stand up well in service and are extremely convenient to carry about and place as needed. They are found preferable to the type first tried, built of heavier channels and ¾-in. pipe and weighing nearly twice as much. For permanent installations, as in the shaft, a much heavier ladder is used, built also entirely of steel.

Notes on the Prevention of Explosions in Coal Mines

By George S. Rice*

SYNOPSIS—The paper gathers together a number of the most important facts relating to explosions, most of which have appeared but may have been overlooked by readers. Noteworthy remarks are that rock dust is proved to be of value and should be used, and that an explosion can as readily originate in stagnant as in moving air except, perhaps, where several shots are fired following each other. In that case the speed of the current may keep the dust in suspension and so in such a condition that it is readily susceptible to inflammation.

Although the explosibility of coal dust without the presence of gas (methane) has been universally conceded by mining men in this country, so that a mining man considers the statement trite that coal dust in the form of a cloud will explode, yet, nevertheless, the development of means of preventing explosions has not made as rapid advance during the past year or two as it did during a few previous years. In certain mines in which disasters have occurred, investigations made by the engineers of the bureau have shown that there have been extensive stretches along the roadway and the sides of passageways in which there was much dry coal dust.

The Moisture Must Be Everywhere

Here and there on such roads there have been wet patches, some of considerable length, and these the mine officials have thought gave sufficient protection against a widespread explosion. Also during warm weather dust precautions have been neglected in many mines, possibly because the emphasis laid on the greater danger from dust in winter has caused relaxation of effort in warm weather.

Further, many mine officials have thought that there is no danger if the entering air has a high relative humidity, although this condition is not in itself an assurance against an explosion. It is only as the current deposits moisture that protection is given. In mines where only scattered places have been wet, an explosion well started has been known to jump the wet places, carrying its own ammunition of coal dust in the advance air wave, and gaining fresh energy on reaching dry places beyond.

Several great disasters during the past few years have occurred in mines rated as "nongaseous." A miner has gone to the face of a working place with an open light, unaware that there had been an accumulation of gas since the last inspection, or since he had fired a shot; the gas has been ignited and the flaming has been sufficient to stir up coal dust and start a great coal-dust explosion that has swept the mine. Some of the mines so swept by explosions were well ventilated and their return air currents carried merely a trace of gas, but methane had suddenly escaped at certain faces where faults or clay slips had been encountered.

One conspicuous result of the investigations of the mining engineers of the bureau is that in not one of the many extensive explosions since the mine-accident investigations began in 1908, has there been anything perplexing or mysterious as to the agent that propagated an explosion through a bituminous-coal mine, although the origin of a few explosions may have been in doubt. Wherever an explosion has passed there has been ample evidence that there was sufficient or more than sufficient coal dust to feed it, if not at every point, then in accumulations at places along the passageways.

Shotfiring in Still Air or in a Current

In the western interior region a theory prevails that explosions are less likely to occur if there is little or no ventilation at the time of shotfiring. Tests at the bureau's experimental mine at Bruceton, Penn., have indicated that an explosion may start from a single shot as readily in a quiet atmosphere as in a strong current.

However, if there has been preliminary raising of coal dust in the air by rapid shotfiring, undoubtedly the dust is more likely to remain suspended in the air when there is a strong current than when the air is quiet, so that possibly the danger of a dust explosion being propagated is slightly increased by the current.

On the other hand, if a mine makes any gas, it is probable that any lessening of the danger of propagation by stopping the fan is offset by the accumulation of gas (methane) at the face. Moreover, it must be remembered that explosions have been propagated by coal dust alone through the experimental mine where before the explosion there was a perfectly quiet atmosphere.

What We Know about Dust Explosions

Tests have demonstrated (*a*) that an explosion of coal dust may become rather violent after it has traveled three or four hundred feet along a passageway; (*b*) that it may reach a violent stage in 500 to 800 ft. from the origin, depending on conditions; (*c*) that an explosion may be made at will in an entry or passageway in which the roof, sides and floor are wet to the touch, if sufficient dry coal dust is present; (*d*) that a high relative humidity of air, which may even be nearly 100 per cent., has in itself no appreciable effect in preventing a coal-dust explosion originated by a blown-out shot, a result that may appear to nullify the recommendation to humidify the ventilating current, as advocated by the Bureau of Mines and by various persons, but does not, since, as repeatedly emphasized, the purpose of humidifying is both to prevent an unsaturated air current from absorbing moisture from the coal dust and to cause moisture to be deposited along the roadways; (*e*) that a single shot improperly placed and loaded with long-flame explosive may cause the ignition of coal dust; (*f*) that it makes no perceptible difference, so far as the origination of an explosion is concerned, whether the air is moving* one way or the other

*Chief mining engineer, Bureau of Mines, 40th and Butler Sts., Pittsburgh, Penn.

Note—Abstract from technical paper 56 of the Bureau of Mines, entitled "Notes on the Prevention of Dust and Gas Explosions in Coal Mines."

*Experiments have not been made to ascertain the effect produced when the air is moving at very high velocities.

at the point of origin or is quiet, but that the important factor is the presence of sufficient dry coal dust; (*g*) that pressures as high as 120 lb. per sq.in. have been measured at right angles to the movement of the explosion, the pressure in the line of advance of the explosion being no doubt much greater; (*h*) that comparatively small quantities of coal dust, 1 lb. per linear foot of entry, equal to about one-fifth ounce per cubic foot of space, will propagate an explosion; a smaller quantity has not yet been tried in the mine†. This small quantity scattered on roof, side projections and floor is barely noticeable.

Are You Sure the Dust Is Wet?

The bureau's experiments have indicated that an explosion cannot originate in thoroughly wet coal dust, because the dust will not be thrown into the air as a cloud by the shock from a shot or by other means, but that it is not easy to wet piles of coal dust even with well humidified air currents. This is an important feature not fully understood hitherto. When a saturated air current passes through a mine it dampens the roof, floor and sides, but the coal dust itself when in accumulations appears to repel drops of moisture; even with long exposure dust like that from the Pittsburgh seam takes up only 1 or 2 per cent. of moisture, though the walls and floor may become damp.

The surprising result of this series of experiments makes it evident that it is necessary to remove coal-dust accumulations, so that, after a passageway has been well dampened, any particles of dust falling on wet surfaces will themselves become wet. It has been observed after some dust-explosion disasters that the explosion has traversed entries in which there was standing water along the bottom, but on the other hand, examination of the benches and projections along the sides of such entries has disclosed quantities of dry dust. Also it has been observed that timbers frequently carry on their upper surfaces quantities of dust sufficient to propagate an explosion. Consequently, the bureau is led to emphasize two precautions, namely, *first remove all accumulations of dry dust and then keep the entries wet or use a coating of rock dust. There will then be little danger of explosion.*

Bureau Commends Rock Dust

At the bureau's experimental mine, experiments have been made with rock or shale dust as an alternative to watering. The dust has been made from the draw slate over the Pittsburgh bed with a hammer crusher having a fine screen, 95 per cent. of the dust passing through a 20-mesh sieve. Tests have been started only recently, but the results obtained supplement and corroborate those obtained at the experimental galleries in France and England, showing that when inert dust or rock dust is placed on all projections and on the floor (even if some coal dust be present it will be buried) the mine will be free from the possibility of an explosion of coal dust.

The bureau's work has not gone far enough to permit the determination of the precise amounts of rock dust necessary, but it is believed that there should be at least twice as much rock dust as coal dust. If the amount of rock dust even equals that of coal dust the chance of an explosion starting is very much lessened; but as more coal dust is apt to be present than is supposed, the only safe plan is to put on the rock dust abundantly.

Taffanel Barriers Are Good But Don't Rely on Them

The bureau has made numerous experiments with the so called "Taffanel barriers," consisting of 10 shelves one-half yard wide and 2 yd. apart, placed over the roadway and piled with rock dust as high as possible, thus forming an obstruction of about 15 per cent. of the cross-section of an ordinary passageway, if this roadway is less than 7 ft. high. More shelves can be employed if the conditions seem to require it. In tests with such barriers explosions have been checked within a few hundred feet after the explosive wave has encountered them. In one test the pressure recorded was 120 lb. immediately before the barrier and only 12 lb. 300 ft. farther out.

In the French gallery the experiments were equally successful; but in the Clarence mine disaster in France, in 1912, in certain places where there was a light explosion and consequently little pressure, the explosion passed the barriers without displacing the shale dust. The failure of the explosion to displace the shale dust was somewhat exceptional and should not lead to condemnation of the barriers as a secondary defense.

Therefore the use of barriers is suggested by the engineers of the bureau as suitable, for example, at the entrance of the ventilating splits, particularly in haulage ways, where there is nearly always an accumulation of dust, and at intervals along the main entries, but they should be considered only as supplementing the other means.

Watch Dust in Gobs and Don't Use It for Ballast

As regards means to lessen the danger of explosions, the prime essential is to reduce the production of dust. The excessive use of explosives, particularly in shooting off the solid, causes large quantities of dust to be blown into the gobs and other inaccessible places.

It is unwise to use broken coal or machine or hand cuttings as ballast for haulage. Even if the coal is in lumps, sooner or later it will be crushed to dust. If an incipient explosion starts, this inflammable material will be thrown into the air and be a source of danger. Use either rock, clay or cinders for ballast.

Shooting "Cracking" Shots Condemned

The use of permissible explosives would prevent many disasters that occur in parts of the Southwest, where so called "cracking" shots are employed. Such shots made by drilling holes 12 to 14 ft. straight into the solid and using five or six sticks of dynamite are a menace both to shotfirers and to the mine and cannot be too strongly condemned.

Permissible explosives of the stronger kinds should also be used in lifting bottom, breaking rock bands or brushing top. There is often as much danger in using dynamite for this purpose as for shooting coal, as coal dust is liable to be present in dangerous quantities. A number of explosions have been caused during the past few years by this use of dynamite.

Mine Car Which Leaks Dust May Later Serve as a Hearse

The second greatest agency in dust making is the mine car. It is often loaded with coal 9 to 18 in. above the

†The theoretical amount of Pittsburgh coal dust, if complete combustion takes place and all the oxygen is consumed, is 0.12 oz. per cubic foot of space.

sides. The coal on a car so loaded may strike the timbers or roof, or be so jarred that it is dislodged and thrown into the roadway, where it is ground to dust by the car wheels or by men and mules or horses. Again, cars with gates or open joints leak dust.

The remedy is drastic, but should be followed. Tight cars and, wherever possible, cars without gates should be used. Wagons of the latter type can only be dumped with a revolving tipple. In Europe, except in Wales and Scotland, tight cars without gates are universally used in coal mines. Side-revolving tipples are employed for dumping the cars, and by proper arrangement the coal is dumped with little breakage. In building or buying mine cars the endeavor should be to get a car as tight as possible, and enough cars should be supplied so that the miners will not be compelled to pile the coal up above the sides.

In addition to tight cars, automatic sprinklers adjacent to the gathering places and sidings should be used so that the cars may be drenched as they pass under a spray. The automatic spray system, operated by a lever depressed or moved by the passing car, is effectively used in a few mines in this country and in many abroad. If well arranged it washes the dust from the top of the car and prevents it from being dropped or blown off by the air currents along the roadway.

Rock Castle Mine Explosion

Special Correspondence

SYNOPSIS—An explosion of gas at the Rock Castle mine located at a town of the same name near Abernant, Ala., killed 12 men out of 90 in the mine. The explosion was quite local. Four men may have been overcome by afterdamp.

Twelve men, five white and seven colored, were killed in a gas explosion which occurred at 8:45 a.m., in the Rock Castle mines of the Davis Creek Coal & Coke Co., at Rockcastle, Ala., on Saturday, Jan. 10, 1914. The mine is located in Tuscaloosa County, about 35 miles south of Birmingham, on a branch of the Louisville & Nashville R.R.

Tipple at the Rock Castle Mine, Where a Recent Explosion Killed 12 Men

Foreman or Helper Ignites Gas

The gas was probably ignited in the 21st room on the 17th right entry, by Mine Foreman Wood W. Quarles and a brattice man, Frank Tillery. All the men killed by the explosion worked on the 17th right entry. Most of those who met death were terribly burned and apparently all but four were killed instantly. Four bodies were found along the heading and it is possible they were those of men who were overcome by afterdamp.

On the morning of the explosion, the fireboss, W. Lawrence, discovered some gas in the 21st, 22nd and 23rd rooms of the 17th right, all of which rooms were idle, and, as usual, he reported them to the mine foreman before the miners entered. Shortly after the miners had gone to their places, Quarles and Tillery, carrying safety lamps, went down to investigate the rooms reported by the fireboss. Just what they did can never be known, as they and all the other men on this heading were killed by the explosion. Mr. Tillery's body was found in the 21st room, about 50 ft. from the mouth and Mr. Quarle's body was on the heading. The 17th right contains 29 rooms, but only those inside of the 24th were being worked.

The mine has generated some gas, during the past year, but has never been considered dangerous and all the men worked with open lights. The mine has been working for a number of years and no fatalities from gas explosions have ever been reported. Some afterdamp was created by the explosion, but most of the recovery work was done without the aid of helmets. All the bodies were recovered by 7 p.m. Some 5 or 6 brattices on the 17th right were destroyed by the explosion, but no other damage was done to the mine and work will be resumed in a few days. No evidence of the explosion was visible on the 17th heading outside of No. 20 room. About 90 men were at work inside the mine when the explosion occurred.

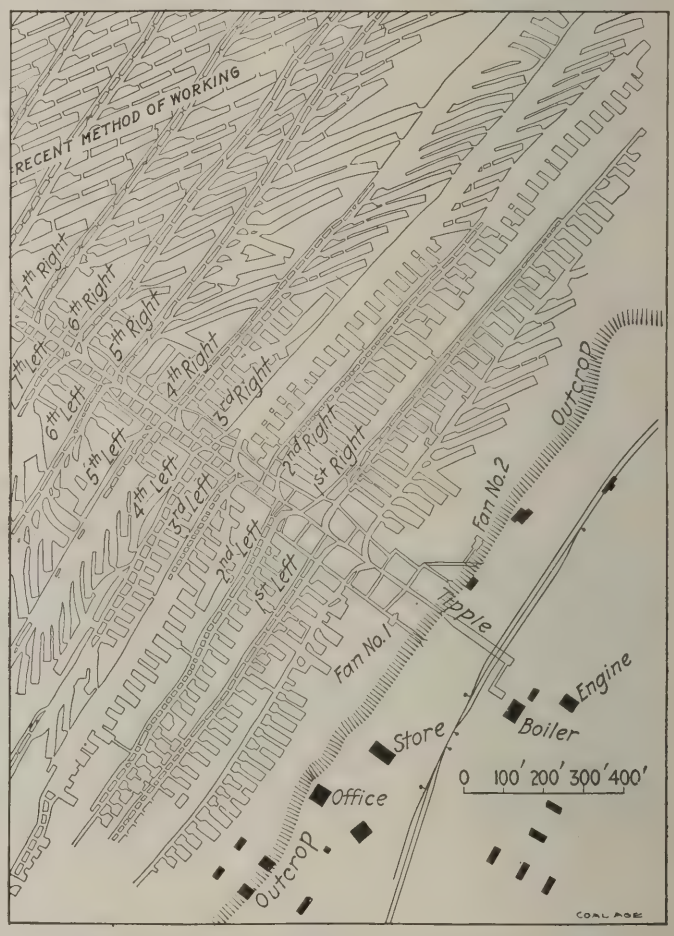
Rescue Work

News of the explosion reached the Birmingham office of the company about noon and almost immediately offers of assistance were received from the Tennessee Coal,

Iron & R.R. Co., which volunteered to send down its car. J. C. Maben, Jr., vice-president of the Davis Creek Coal & Coke Co., decided that the "Tennessee" car could not reach the scene of the accident in time to render service, but requested that the Government auto truck be started immediately. It was found that G. B. Sutton in charge of the Government rescue station was out of the city, delivering a lecture at one of the mines of the Alabama Fuel & Iron Co.

Mr. Hamilton, of the DuPont Powder Co., and Mr. Newby, of the Jefferson Powder Co., were then communicated with, as they had made several runs with the automobile rescue car and they consented to take the truck to Rockcastle at once. They arrived there about 3 o'clock. Chief State Mine Inspector, C. H. Nesbitt and assistants, F. Hillman and D. Kelso, left at once in an automobile, as did also J. C. Maben, Jr., vice-president of the company. Assistant Inspector Smith, who happened to be in Tuscaloosa County, was notified by wire, and joined the others at Rockcastle.

Scene at the Mouth of the Slope after the Explosion



Those who lost their lives are: Wood W. Quarles, mine foreman, Frank Tillery, brattice man, 3 Austrians, Phil Malner Joe Bosneck, John Hondlin, and 7 colored men, John Brown, Elmore Lyons, Nathan Blakely, Sam Brown, Harry Tinker, Charles Fancher and Dennis Thomas; Nathan Blakely and Sam Brown being drivers.

Only the men in the headings above and below the 17th right knew that anything unusual had happened and some of them immediately rushed outside and notified George Kuffner, the superintendent. Word was then sent to all the men in the mine to come out immediately. As soon as Mr. Kuffner was sure that all the men were out, with the exception of those working in the 17th right, he had a brattice put across the slope at that heading and reversed the air current, making the heading the intake so that all the incoming air was forced up into that entry. When this was done, the rescuers were able to penetrate to the face of the 17th right without helmets, but they did not attempt to go into the rooms, until the helmets arrived. Eight bodies were located before that time. A. H. Witt, the mining engineer of the company, accompanied the rescue crews, as, next to the mine foreman who had been killed, he was most familiar with the mine workings.

Mining Conditions

The mine is opened on the Jagger seam which pitches at about 18 deg. at this point and consists of a single slope, with an airway on either side. Right- and left-hand entries are driven off this main slope. Roof and top are excellent and taking into consideration the thickness of the seam, which is 6 ft., mining conditions are good. The coal is mined with picks and shot down with the permissible explosive "Monobel." Ventilation is induced by two blowing fans, one on either side of the main slope, and has always been considered ample.

The mine was opened eleven years ago by J. C. Maben, Jr., who was then a young mining engineer, almost fresh from college. The venture was so successful and reflected so much credit on the young man's management, that two years ago he was elected vice-president of the Sloss-Sheffield Steel & Iron Co., one of the largest iron and coal corporations in the South. He still retains his holdings and office in the Davis Creek Coal & Coke Co. Geo. Kuffner, superintendent of the mine, is a brother of a former assistant state mine inspector.

The Rock Castle Mine, Rockcastle, Ala.

The workings in the 17th right where the explosion took place are like those in the 7th, 8th and 9th right.

As in all mine accidents, the scenes at the pit mouth, following the explosion, were pathetic in the extreme. There, huddled together, anxiously waiting, were the sorrowful wives and mothers of some whose fate was all but guessed, and watching with them, stood the young man whose enthusiasm, but a few short years before, had brought them there.

An Analysis of the Ohio Mining Commission's Report

By A. T. Shurick

SYNOPSIS—The gradual leaning toward paternalism, on the part of both state and federal governments, is becoming more and more marked. The investigation of the Ohio legislature is the most important step that has been made in this direction, so far as concerns the coal industry. The changes proposed are of such a radical nature and will indubitably be so far reaching in their effect on legislation in other states, that coal engineers in all parts of the country are closely following the progress of the movement. The issue is of such importance that the recent report of the commission appointed to investigate the situation justifies more than the ordinary review. The present installment of the review takes up the preliminary considerations.

In the face of severe criticism on the part of the coal press generally throughout the country, Ohio has quietly persevered in its determination to solve the problem of providing an equitable basis of payment for her miners. In pursuance of this plan, a report has been compiled dealing with this question in all its ramifications. The report, as a whole, reflects creditably upon the commonwealth and, incidentally, forms one of the most valuable treatises on certain branches of technical coal literature that has ever yet been published. It is such a report as could only be compiled by months of careful and painstaking research work.

It is obvious to the most casual readers that the authors have approached their task with minds open to conviction. They have consulted and examined reputable authorities recommended by both sides of the question and have shown a keen insight where any attempts at misconstruing the actual conditions were made. They visited most of the mines in their own state, and some in others, as well as a number of the large consuming plants and distributing centers. Their conclusions are honest, accurate, and, in the main, founded on the soundest practice in coal mining.

While the subject has been handled in a masterful manner, it is none the less true that the commission has placed itself on record as favoring concededly radical innovations—changes which are regarded by some as the visionary effervescence of the impractical altruist. But it is equally true that our best students of mining economics are agreed that it is only a question of time until some of these proposed changes become accepted practice.

The pioneer in new thought lays himself open to much criticism from the more conservative element, and since the province of the reviewer is destructive rather than constructive, impartial and unbiased issue is freely taken throughout this paper with many of the findings of the commission.

Geology and the Coal Reserves

As becomes a monograph of this character, designed as it is rather for the *dilettante* than the professional, a labored effort is made throughout to maintain as non-technical phraseology as possible. The report opens with a brief and clearly expressed synopsis on the modern theories of coal formation. It is regrettable in this connection that local authorities are quoted to the exclusion of all others; surely, Dana, Le Conte, or the more modern Salisbury and Chamberlain would have carried greater weight with the well informed reader. This almost provincial disregard for the world's accepted authorities naturally affects the prestige of the report in the minds of the professional.

In addition to this, the paper is rather overburdened with considerable speculation regarding the actual coal resources and what these might have been under other conditions. "Something like 10,000 square miles" is given as the estimate of the coal-bearing area in Ohio. It is rather strange here that the United States Geological Survey reports should have been so completely ignored, particularly since these give actual tonnage figures and not the rather meaningless square miles.

Thus we find the geological survey estimates the area "known to contain workable coal" at 12,660 square miles, containing originally 86 billion short tons of coal. From the earliest time for which records are available, in 1838, to Jan. 1, 1913, the total extraction has been only 646 million tons, or 0.0075 of the total original supply, less than 1 per cent. In view of the fact that the commission lays considerable emphasis on the importance of conserving the coal resources, it seems only fair that the best information available on this subject should be included.

It also appears that the commission might advantageously have quoted like figures for other coal districts, in order to give the reader a basis for determining the relative status of Ohio as compared with other fields. For instance, the situation might aptly be compared with conditions in England where the coal reserves are estimated at 147 billion tons. The *annual* production there is at the rate of 270 million tons, or about 0.002 of the total supplies, while Ohio's *gross production* during the three-quarters of a century since the inception of mining is only 0.0075 of the reserves, as already pointed out.

Conservation and Competition

Mining and conservation of the coal is the next topic taken up. The commission reiterates the already generally accepted conclusion that more effective systems of mining must be employed in order to obtain a higher recovery. As compared with other states, a rather broad hint is given at the backwardness among Ohio operators in adopting modern methods of mining.

After justifying its position in taking up the conservation phase, the commission goes into a detailed discussion of this question, particularly from the point of view of the mining man. A regrettable feature of the investigations along these lines is the persistent policy of giving preference to the testimony of geologists. The problems arising in this connection are those of the engineer entirely. It is essentially a question as to whether the coal can be economically mined in such a manner as to

effect the maximum recovery, and this is clearly one for the engineer and not the geologist. It is not within the province of the geologist to determine issues in practical mining, and it is a disappointing feature of the report that utterances based upon the impractical altruistics of men entirely uncontrolled by the economics of competition should be given such weighty consideration.

It is here noted with much interest that the commission takes a sharp rap at "our drastic anti-trust laws, both National and State." It has been pointed out repeatedly that conservation and competition in the coal industry are *concordia discors*. On the one hand the operator is accused of despoiling the Nation's coal reserves and urged to adopt systems and methods for eliminating this waste. On the other hand, he is being forced to market his product under the most adverse conditions conceivable, and often at a figure that scarcely covers the cost of production. Where, then, are the additional funds necessary to the adoption of more efficient methods of working to come from?

Thorough Preparation Must Be Assured

Passing over half a dozen pages on the nomenclature of the Ohio coal horizon with comments upon the economic possibilities of the different seams, we arrive with interest at the opening gun on the mine-run discussion. In a general prologue the commission emphatically states that: "Unless the Ohio coals are carefully mined and are reasonably free from impurities, they will reach the Northwest in a less satisfactory condition than the coal of other fields, and in such keenly competitive fields, the margin of profit is very low." The commission further states that "the Ohio operators would soon be driven out of their most valuable markets" unless they can "guarantee clean coal, mined in such a way as to bear transportation in large lumps."

Much testimony was taken by the commission to bring out the proportion of coal lost by the present systems of mining in Ohio. The different authorities examined placed this, under normal conditions, at a minimum of 25 per cent. to 35 per cent., the commission itself, from the results of its examinations, being of the opinion that from 35 per cent. to 40 per cent. was left in as pillars, while it often ran as high as 40, 45 and even 50 per cent.

Systems of Mining

Following this the commission naturally turns to the various systems of mining used in the state, in order to demonstrate how these losses occur and prescribe remedies for same. The report segregates the systems in this country, under four general headings as follows: Wide room and narrow pillar system; narrow room and thick pillar system; the panel system, and the longwall system.

Wide Room and Narrow Pillar System—It would be surmised from the report, that this system is used mostly in small operations, where little consideration is given toward effecting a large recovery. One of the principal objections which the commission takes to this method, as regards the present controversy, is the difficulty in getting miners to work pillars which have been badly crushed by the abnormal load thrown upon them. Naturally such coal would yield a maximum proportion of slack, which the miner is not paid for, and the objection is well founded.

..*Narrow Room and Thick Pillar System*—This method differs from the one just described in that larger pillars are left with a view to ultimately recovering these when the mine is abandoned. It is estimated that as high as 90 per cent. of the entire seam may be worked out by this system, although probably on an average of from 75 to 80 per cent. is about all that is generally mined.

The Panel System

Panel System—After a brief description of this method the commission goes into a detailed discussion of it. Obviously it meets with great favor. As pointed out in the report the method is not adaptable to districts where land values are high, because of surface subsidence, but inasmuch as the mining regions of Ohio are generally hilly and of little value for farming purposes, this objection loses in importance.

It is noted here that the commission shows a commendable leaning toward the more advanced methods of mining, particularly those now practiced in West Virginia. Thus the Gary, W. Va., mines of the United States Steel Corporation, operated under leases granted by the Pocahontas Coal & Coke Co.,* are heartily commended by the commission.

Taking up the question as to why Ohio operators have not voluntarily adopted the panel system of working, the report ascribes this partially to a general belief that this method involves a much greater initial expenditure. This, the commission thinks, is due to the erroneous belief that all narrow work must be driven out to the boundaries before the work of extraction on a large scale can be undertaken. The report correctly disabuses this theory by stating that active mining may be prosecuted as soon as sufficient development work has been done to open up a single panel. While this, of course, is true, it none the less conveys a wrong impression, since the expenditure necessary to accomplish this is ignored; it is difficult to conceive a system of panel working that would not require at least half a mile of development work, consisting of from two to four entries. Driving such an amount of narrow work obviously involves not only a large expenditure but an important interval of time.

As the main reason for the objection of the operators to the adoption of the panel system, the commission believes that this is due to the extra expense incident to driving entries and working narrow places. It must, of course, be conceded that this system requires a greater amount of entries, and the operators are indubitably justified in their stand in this matter, providing a proportionate increase in the market value of their product cannot be obtained.

In so far as this objection applies to driving narrow rooms the position of the companies is not so well sustained. While it is true that the use of narrow rooms is commonly applied in the panel system, this is not by any means essential. As a matter of fact, the system originated in fields where the roof could not be held except with narrow places, such as, for instance, the Connellsville district. While roof conditions in Ohio, as a rule, are not particularly favorable, there would hardly be any logical reason for adopting the narrow rooms used in the panel system in West Virginia. The miners also

*A complete detailed description of the panel system in the Pocahontas field will be found in "Coal Age" this week. Descriptions of other systems used in West Virginia will also be found in Vol. 1, pp. 278 and 305.

find objection to this method, under the present basis of payment, for the reason that it does not yield such a large proportion of lump coal.

Longwall System—Although the commission says: "This is undoubtedly the best system of mining wherever it is practicable," the report disposes of it in a single brief paragraph. This it does on the grounds that "it is generally admitted by practical miners and mine operators that this system could not be employed to any considerable extent in Ohio." In a report so replete with innovations of every character, it is rather disappointing to see this system passed over in such a casual manner. To the true conservationist the longwall system is looked upon as the millennium.*

Regulating the System of Mining

As to a general corrective, the commission rightly points out that no one system of mining could be specified for the reason that many mines now operating could not conform to such a system or could do so only at a prohibitive expenditure. But the commission does boldly advocate a departure from accepted practice by recommending state supervision of the systems of mining employed. It is worthy of note in this connection that many conspicuous figures in the coal industry today, as for instance Francis S. Peabody[1] and other of our ablest thinkers, look with favor upon some such regulation.

The first question that naturally arises is how such a plan will work out where the Ohio coals come into competition with those from adjoining states not so handicapped. While the plan certainly has much to recommend it and indications are that the no far distant future will see it in general practice, it is none the less inevitable that the pioneers will suffer a certain economic disadvantage. The measure is similar in many respects to the building laws in effect in all cities, and aside from the economic aspects there are no reasonable grounds why it should not be a success, providing it is not made the toy of unscrupulous politicians.

In justification of legislation along this line, the commission points out the fact that there is similar supervision exercised by the Pocahontas Coal & Coke Co. in connection with the leases of that concern. This is rather an unfortunate comparison. As is well known, the Pocahontas Coal & Coke Co. is essentially a holding concern, controlling practically the whole, or at least the best part of the original Pocahontas coal. Since this is one of the highest-grade fuels, if not the highest, in the country, it commands a ready market at any time. The marketing of coal at a profit is the most vital problem in the fuel industry today, and it is obviously unfair to compare Ohio, with her relatively lean coals with a district so advantageously provided for in this respect.

The commission concludes Part I of its report with flattering comments on the safety precautions at Gary, W. Va.[2] The report says: "Nowhere has this commission seen such elaborate and complete precautions taken to prevent accidents as are to be found in the mines operated under these leases by the U. S. Steel Corporation."

The Fatality Problem

Part II of the commissioner's report deals with "Prevention of Accidents." After justifying itself for taking up this phase of the question, the commission states in a general prologue that the adoption of the panel system of working would not only be an important conservation measure, but would also tend to lessen the number of accidents due to falls of roof and coal.

Attention is called to the well known fact that most of the fatal accidents are due to this cause, and the commission is of the opinion that most of these could be prevented by the adoption of similar strict rules as those already mentioned at Gary, W. Va. Comments are also made on the fact that one-half the fatal accidents in the Ohio mines are sustained by men of foreign birth, and some well defined conclusions are drawn on the lack of experienced miners in the Ohio field. It is generally conceded by all coal engineers that this is a prolific cause of fatal accidents.

Having thus prepared the way for further departures from accepted practice, the commission promulgates its recommendation: "Need of Safety Foremen." Casting about for a means for justifying its position in this matter, the commission lights upon its illuminative, if not convincing, analogy between coal mining and railroad-maintenance work. Thus it is pointed out that every few miles of railroad has a section gang of six or eight men under the direction of a section boss, while "there are often times found many miles underground workings in which are employed one or two hundred men with only the supervision of a boss and one or two assistants."

Considering the personnel of the commission, it is indeed surprising that such an obviously unfair comparison should be allowed to creep into their records. As everyone knows, railroad work of this character requires continuous and experienced supervision to insure sustained effort on the part of the workmen, and that the work be properly executed. On the other hand, the miner, once started, works in a purely mechanical manner and is remunerated in direct proportion to the amount of labor performed.

As is pointed out in succeeding paragraphs, however, a closer supervision of mining work will no doubt do much toward reducing the fatality rate. Coal mining naturally does not attract a high class of labor which accentuates the dangers and makes essential that the work be carefully watched.

A Study of the "Safety Foremen" Proposal

The commission places itself on record emphatically and positively, as recommending the enactment of a law requiring the employment of a safety foreman for each 25 miners. In addition, it is of the opinion that these safety foremen might well be given police powers for the purpose of arresting miners violating the rules. It is proposed that these foremen be required to fire all shots, which is undoubtedly a commendable provision, since it places this dangerous work in the hands of what should be, at any rate, experienced and competent men. This proposition to inject a tone of militarism into mine operations, although a new departure in this country, still has much to commend it. This has been developed, to a large extent, in European mines, particularly in Germany, and with gratifying results.

In this proposal to engage safety foremen we again encounter the question of economics, but it is noted with satisfaction that the commission faces the question square-

*An interesting paper on longwall and conservation appeared in "Coal Age," Vol. 1, p. 475.

[1]See "Coal Age," Vol. 3, p. 691.

[2]See "Coal Age," Vol. 3, p. 347 for a detail description of these safety precautions.

ly. The report agrees that the operators would naturally take issue with this condition on the ground of the additional expense, but it is rather surprising to find that it says further: "The expense of operation would not be increased by the full amount of these wages and probably not at all." Presumably, this is to be accomplished by having the safety foremen devote a portion of their time to other duties. Such a scheme is hardly to be recommended for the reason that the distinguishing line between the ostensible occupation of these men and the other duties they were called upon to perform would gradually disappear with the result that their usefulness in this connection would ultimately be destroyed. Such has been the experience in most instances where a firm stand has not been taken in the matter, and the men held closely to a single duty.

Cost of the Safety Foremen

In order to arrive at an approximation of what expenditure would be involved in the employment of these safety foremen, let us assume there are 35,000 men* in Ohio engaged in mining coal at the working face. If one safety foreman be employed for each 25 of these men, this would necessitate 1400 additional men, which, at $3.50 per day, would mean $4900 per day. Assuming the mines to work 200 days[1] this would mean an annual expenditure of $980,000. Computed on the basis of a production of 34 million tons, this amounts to 3c. per ton. Whether the Ohio coal industry is prepared to carry this additional burden is a grave question and one that must be given serious consideration.

The commission further points out that, under the new workman's compensation act, the 100 deaths occurring annually in the Ohio mines, as the result of falls of all kinds, will involve an expenditure of $375,000 in indemnities, and suggests that a reduction in a considerable proportions of these would wipe out much of the cost involved in employing the additional men. Properly carried out, this system will, no doubt, effect an important reduction in the death rate, as has been proved at Gary, but even the complete elimination of all fatal accidents which, of course, is not conceivable, would only reimburse the operators for one-third of their loss.

One rather gathers a feeling at this point that a tone of partiality is creeping into the report. The commission is so obviously in favor of their recommendation that they have quoted the exponents of their theory to the exclusion of all others. It is true that the opinions of the engineers of the Pocahontas company are due every consideration. But the fact that a single large and powerful corporation, operating under abnormally favorable conditions, should see fit to apply concededly altruistic policies in the conduct of its affairs is certainly not sufficient grounds to justify the Ohio Legislature in forcing like measures upon their operators who are not so economically favored.

Efficiency tests for the miners is the next topic taken up by the commission. This was a measure advocated by the miners themselves and had for its purpose the testing of applicants for work in the state to determine their competency. It was proposed that all miners should be compelled to pass an examination and obtain a certificate before being permitted to accept employment. The ineffective results obtained by like measures in other states made the adoption of any such system impracticable in the opinion of the commission. Part II of the report closes with a few remarks on shooting coal off the solid.

"Unusual Character of the Miners' Demands"

Part III of the report, dealing with "Screened Coal vs. Mine-Run System of Payment," is turned to with much interest. The beginning of this part is taken up with the history of the controversy in which it is pointed out that the screened-coal basis of payment originated when the finer grades had no commercial value. When it was later found that this coal was of value, the miners repeatedly found fault with the system of payment. As early as 1883 a commission was appointed to report on this matter, and the present commission states that the controversy remains much the same, as regards the arguments of both the miners and the operators, as at the time of the previous report.

In this contention one immediately perceives the "leveling process of unionism" with a tendency to consider the successful accomplishment of a highly speculative business venture (as all mining investments are regarded) as an economic crime. The argument lacks nothing in persuasiveness but even sympathizers with social reformation will not concede the general assumption that all capitalistic interests are to be regarded as wealthy malefactors. Surely the men whose fortunes, brains and courage have been boldly flung in the balance are entitled to reap the reward of their efforts.

Under the subheading, "Unusual Character of the Miners' Demands," the report points out that these are unusual because of the fact that they call for "legislative interference in a matter which is usually left to contract between the parties concerned." It further states that such demands are usually made in behalf of women workers or children and others unable to protect themselves, while in this case the legislature is asked to interfere in the interests of the "strongest labor organization in the country." In fact, one is much impressed with the feeling that the demands savor somewhat of a labor official's boast, made during a conference between certain railroads and their employees, to the effect that: "You will give us the advance we ask across this table or we will go down to Washington and get it."

The commission finds the situation particularly incongruous in this instance, because of the fact that the wages paid to the members of this organization constitute a large share of the total wealth produced by their labor. But when it is noted that the report says further, "and when one considers the hazards of the occupation he cannot wish it otherwise," an obviously wrong impression is conveyed. In point of numbers the coal-mine fatalities are exceeded by such elemental risks as child birth, and burns and scalds, while railroads head the list by a large margin. In 1906, the fatality rate per thousand in the bituminous-coal mines was 2.77, being exceeded by eight other vocations, that for railroad switchmen being 4.50 and the trainmen being 7.46.

It is a rather notable fact that the commission concludes its comments on this phase of the question without justifying legislative interference in any way.

(To be Continued)

Editorials

Seismic Disturbance in Its Relation to the Flow of Gas into Mines

For a number of years past this subject has received growing attention on the part of mining men, especially those engaged in the work of investigating the causes of mine explosions.

The excellent paper presented by N. H. Darton, geologist, U. S. Geological Survey, Friday evening, Jan. 16, before the New York Section of the American Institute of Mining Engineers, on the subject, Mine Gases, gave rise to an interesting discussion of the possible effect of a more or less severe seismic disturbance at one point on the globe, to cause an increased inflow of gas into distant mine workings.

While it was freely granted by all that any simultaneous occurrence of one or more mine explosions, accompanying or shortly following an observed and recorded seismic disturbance, could not be taken as produced by one cause; yet such coincidences at least suggest a possible relation between such phenomena.

Numerous notable examples of *danger periods in coal mines* occurring simultaneously with *periods of seismic unrest,* it was generally agreed, make it a reasonable matter for careful study and investigation. As examples of such coincidences in recent years, may be cited the Mount Pelée period, 1902, marked by the loss of 550 lives in four mine explosions; the Formosa, Japan, 1906, costing several thousand lives and $45,000,000 property loss, marked by the terrible Courrières explosion in which 1200 lives were sacrificed, the Takashima explosion, 307 lives, and a number of less fatal explosions in West Virginia and Colorado; which was almost immediately followed by the San Francisco disaster that destroyed $300,000,000 worth of property and over 2000 lives, the entire period covering less than two months and followed four months later by the destructive Valparaiso earthquake with a property loss of $250,000,000 and 7000 lives, which was almost immediately followed by a remarkable series of mine explosions at Bluefield, W. Va., 30 lives; Raton, N. Mex., 15 lives; Windgate, Eng., 25 lives; Johnstown, Penn., 7 lives; Pocahontas, Va., 35 lives, etc.

This was followed, again, by the Kingston, Jamaica, disaster, January, 1907, with a $10,000,000 property loss and 1000 lives, which was coincident with the renewed activity of Mt. Ætna and earthquake in Sumatra, costing 1500 lives. Simultaneous with this outbreak was the loss, in mine explosions, of 24 lives at Primero, Colo.; 250 at Essen, Germany, 12 at Lorentz mine, 84 at Stuart and 25 at Thomas, W. Va., and numerous others in other states.

In September of the same year seismographs at Washington, D. C., and in the Isle of Wight told of a severe earthquake as having occurred in the Arctic or the South Atlantic Oceans, followed by the loss of 200 lives by mine explosions in Texas, Rock Springs, Wyo., and Wilkes-Barre, Penn.

The remarkable concomitance of these periods of seismic unrest and danger in mines due to prevalence of gas point to the consideration of the globe as a unit, sensitive in a varying degree to the physical changes in its crust.

Once More!

The reader will forgive our repeating much of what we said on Jan. 3, because G. O. Smith, director of the Geological Survey, in a letter which we publish in this issue, declares to all intents and purposes that he misapprehended our editorial.

The reader will remember that we said on Jan. 3 that not all the coal lands sold since June 30, 1907, had been classified by the Geological Survey and were sold at the price set by the Bureau. We said, therefore, that the statement of "sales at *all* prices" which was presented in a declaration to prove that coal lands were held at reasonable figures was misleading.

We also said that the sales listed as made before the date mentioned were a small fraction only of those which actually took place. That all other sales were void in law is doubtless true but it does not invalidate our statement that coal-land sales of a valid character were prevented by the notion that valid titles could be obtained at less cost. This statement also was amply proved by official testimony and other witness could be given from G. O. Smith's own bulletin published in 1913.

We further said that as prices had been changed the sales at an early date did not establish the reasonableness of present-day prices. We believe, therefore, that the comparison was misleading. How much of an inaccuracy was introduced we cannot say positively, for from what we learn no account has been kept by Land Office or Geological Survey as to the sales of unclassified land since that date nor as to the invalid land patents prior thereto. We thought we made plain what our difficulty was, but Mr. Smith does not seem to have realized it despite reading our correspondence with him and with the Land Office. We made careful inquiry as to the volume of unclassified lands sold and got no statistical answer.

We did not take an exception, as Mr. Smith appears to think, to the differences between the Land Office and the Geological Survey in estimating sales. It is true we sent the Land Office the figures of the Geological Survey, and we received a letter stating that our figures were wrong and the writer did not know where we got them. But we made no reference by word or implication to this fact.

Now we cannot condemn Mr. Smith for this inaccuracy. His explanation of it is, however, amusing. He states that he could not tell from an inspection of the books when sales were made. This frank approval of the frequent contention of the Western patentee is refreshing. He has been complaining for years that he didn't know when he had effected a purchase and loudly has he berated the Land and Attorney General's offices, mostly, however, behind closed doors. Rightly or wrongly he be-

lieved the way to secure his holdings was to refrain from adverse criticism of governmental departments and bureaus. We are glad that by Mr. Smith's letter the uncertainty of his tenure has in our columns received official recognition.

Mr. Smith regrets that we did not copy the more elaborate table in his report of 1912 showing "Sales of Coal Lands at Various Rates since July, 1907." It is an omnibus list which does not segregate classified from unclassified lands. What, therefore, does it import to this controversy?

The 1913 report which Mr. Smith quotes, in a way which might make the reader think we have seen it, has not been received by us, the New York Library or the Engineering Societies' Library. We have the honor of being on the exchange list of the Geological Survey and should be favored with all such bulletins as soon as any one.

The latter part of Mr. Smith's letter refers to the condition of the coal business in the West. The prices of coal in the public-land states, as we showed editorially Jan. 10, have been comparatively steady since 1907 and we are prepared to concede that the jump in that year was not necessarily chargeable to the action of the Interior Department. But the prices in the public-land states are and have been for many years much higher than in the United States as a whole and show a climbing tendency. The difference between the figure $1.15 for the whole United States, given by Mr. Smith as against $1.65 for the public-land states as given in our editorial of Jan. 10, is sufficiently marked and perhaps we may consent to overlook the well known statistical rule that when you want to compare the wage of Sam and John per day, do it; don't compare the wage of Sam with the average wage of both.

In other words, the price of coal in the *West* should be compared with the price in the rest of the United States. His table of prices is the second table in Mr. Smith's answer to our editorial and we would like to call it "Exhibit A" and use it in rebuttal of his charges as it shows how much higher Western coal prices are than those in the East.

The first table is also one which to our statistical friends is, by nature, anathema, though it has, at times, an appropriate purpose. If you wish to find how much the output of coal in the Appalachian regions has increased, compare it with itself and not with the whole output of the United States or any other quantity.

If John puts out 99.5 tons per month and Jack 0.5 tons, together they produce 100 tons per month. Next month John decides to raise his percentage and mines 199 tons. Jack still puts out a miserable half ton. John's percentage of the whole output is 99.75 despite the fact that his actual production has doubled. By the method of investigation pursued in the table, his increase in output is from 99.5 per cent. to 99.75 or a beggarly ¼ of one per cent., whereas, by every reasonable rule of calculation, it is 100 per cent.

Such a table is misleading, though not, of course, to the degree used in the illustration. As a matter of fact from 1906 to 1912, the bituminous output of the pushing West increased 25 per cent. and in the rest of the Union 31 per cent. We would expect the West like the United States to forge ahead and the East like England to drag behind. For the East is relatively effete, that is, the opportunities for development are more largely already effected. It is interesting to note that from 1910 to 1912 a decline in output was recorded in the public-land states.

There remains for us another statement in civics. Mr. Ashley asked us to say the Survey did not sell land, Mr. Smith desires us to admit that it doesn't make the law. Can Mr. Smith contend that Congress makes prices of coal land when the law of 1873 still holds and some land has risen in that time from $20 to $600 and the law is still the same except that the Geological Survey has been authorized to evaluate the land? The prices are made without approval of Congress, without the signature of the President, according to rules over which neither have exercised any control and Mr. Smith has been the adviser from the beginning.

Did not he and Garfield designate coal land, as land containing a 2-ft. coal bed or coal not over 1500 ft. deep? Did not he and that same conservationist make a new declaration in 1908 and less than 3 months later make another, dubbing land containing coal 3000 ft. below the surface and coal 2 ft. thick, coal land?

Did not he and Ballinger make new regulations dignifying a seam 14 in. thick as coal under the act of 1873 and then finally did he not in the year just passed make a new code with Mr. Fisher so complicated that probably none but a member of the Survey could understand it? Not only is the present scale his scale, but he has repeatedly defended it. If he did not believe in the scales and opposed them his advice was rejected by three successive secretaries and he was not "intellectually honest" in his defense of what he considered wrong. We are sure, however, he *does* believe in these scales and is "intellectually honest" in his approval of them and therefore we cannot refrain from holding him responsible for their framing. They are too complicated and reveal too well trained a mind to emanate from men like our secretaries who have never, perhaps, entered a coal mine.

When Mr. Smith says he does not make the laws, we presume he must mean that he is not chargeable with having maintained the present selling system as opposed to leasing. This we readily grant, and we give him every credit for wishing and urging a change, but we have all the time urged that present prices are altogether too high and we hold that he *is* largely responsible for that fact.

Explosibility of Coal Dust

Perhaps one of the most interesting findings of the British investigators who have been working on the problem of mine explosions, deals with the question of coal dust as a factor in such accidents. It is pointed out that the inflammability of such a dust depends more on the percentage of "paraffin-yielding" constituents than on the total content of volatile matter in the coal. However, when once inflammation has been effected, the presence of matter capable of readily yielding inflammable gases on heating is not essential for the propagation of a serious explosion. That such constituents in dust are not necessary for the propagation of a violent combustion has been proved by explosions obtained with wood-charcoal dust, which element does not contain any volatile matter. The scientific conclusion, therefore, is that the violence of a dust explosion depends, not on the volatility of the coal, but on the calorific value of the dust. If this is true, anthracite dust, though difficult to inflame, will ultimately produce an explosion as violent as those produced by high-grade bituminous coals.

George Otis Smith Replies to Editorial Criticism

SYNOPSIS—The Geological Survey reports on coal sales, while probably not absolutely in agreement with those of the Land Office, were compiled with full intent to obtain correct results. The statements that the increase in the price of public coal land has reduced production and raised the price of coal in the West is disproved by statistics.

In your editorial in COAL AGE for Jan. 3, you say: "All in all, the report made year after year to the President is misleading in the extreme. The public have been deluded. The high cost of living is being raised in the West by the restriction of competition in that section."

In replying to your editorial, I do not care to match skill in invective but merely to answer two charges; the one concerning my intellectual integrity and the other relating to the adverse effect of the present policy upon the ultimate consumer in the public-land states.

THE GEOLOGICAL SURVEY ENDEAVORS TO PRESENT THE WHOLE TRUTH

"Misleading" and "deluded" charge intent to deceive. Apparently, you expect to find the administrative report of even a scientific bureau taking the same liberties with facts as a paid advocate. My associates, I am glad to state, condemn special pleading wherever found and we consider that any member of a Government scientific bureau who might withhold a single pertinent fact or "cunningly arrange" facts so as to support an opinion or theory is unfaithful, both to the people he serves and the science he represents.

In the U. S. Geological Survey we may misinterpret the facts at our command and thus reach unwarranted conclusions, but when, because of new facts or of a new viewpoint, we recognize an error, we intend to present the new opinion with the frankness that should ever characterize the search after truth.

If the simple table quoted by you from the Director's report for 1912 did not satisfy you as a fair presentation of the matter, you had only to look on the next page to find the more elaborate table, not reprinted by you though utilized in your argument, which table shows the sales at each acre price from $10 to $410. This table is brought forward a year and printed, on p. 148, in the 1913 report. Comparison of these tables shows that more than 80 per cent. of the sales for the intervening 12 months were at minimum prices, verifying the statement in the 1912 report that "purchases will continue to be made mainly at the minimum prices."

ACCURATE STATISTICS HARD TO CULL

It is difficult to cull from the voluminous and complex records of the General Land Office accurate statistics of coal-land entries and sales. Uncertainties as to what should be considered the actual date of sale, the cancellation of final certificates and even patents, and the necessity of assembling reports from the numerous registers and receivers, complicate matters. The Survey heretofore has compiled, as best it could, from the files of the General Land Office the records of sale for inclusion in the Director's annual report. This compilation has usually preceded that made by the Land Office for its own purposes. That, notwithstanding our care, these figures have later been found to differ from the final figures issued by the Commissioner is, of course, to be regretted, although these differences have not been regarded as a matter of importance.

The only difference that possibly could have misled the reader is the larger number of entries cited in the Survey table, plainly due to duplication in the effort to itemize the acreage sold at the different prices. As our conclusions have been based not upon a comparison of the number of entries but only upon the acreage sold, there is evidently not the intent in this oversight that you have charged.

THE DISCREPANCY BETWEEN LAND OFFICE AND SURVEY FIGURES

The Land Office figures, further, effectually dispose of any implication that the Survey has deceived the President and the public by an exaggeration of the actual number of sales or acreage or returns. For, as reported to you by the Commissioner of the General Land Office under date of Dec. 3, 1913, instead of 829 entries of 133,000 odd acres, bringing $2,461,000 odd, as set forth in the Survey's report, there were 940 entries of 146,246.79 acres which brought $2,780,283.10, during the period July 1, 1907, to June 30, 1912.

Finally, I believe that the figures presented in the two tables in my report for 1912, as well as those published by the Commissioner of the General Land Office—which, by the way, show a larger acreage sold during the fiscal year 1912-13 than during the preceding year—fully justify my statements that coal land has continued to sell at the new figures at a moderate rate, and one comparable with that of the earlier years, and that "these sales indicate that the suggestion once made that coal lands would not sell at the new figures was not well founded."

GEOLOGICAL SURVEY ONLY ADMINISTERS LAWS

Whether or not my interpretation of these facts agrees with yours may not be essential, but it is all-important that the available facts have been fairly presented by the Federal Bureau.

It will be regretted by all men who seek the truth that a journal of the standing which the COAL AGE should have, considers it advisable to inject, into what should be a friendly and fruitful discussion of a broad, national question, imputations against the honesty of those who are compelled to differ with it as to the proper solutions of that question. I am constrained to believe that you will find no support, as you deserve none, in the charges you have made.

So long as existing laws remain on the statute books, they must be administered, even though those who administer them may believe that a law expressing a different policy would be better.

HAS THE WESTERN OUTPUT SUFFERED?

The only other topic under discussion, for which I request further space in your columns, is the larger ques-

tion of how the coal-land policy has affected the price of coal to the consumer. Paralysis of the industry has been freely charged ever since 1906, but whether there has been any serious checking of production perhaps can be determined best by a comparison of the statistics for the years before and after the adoption of the present coal-land policy. These statistics, which are available to anyone in the Survey's annual volumes on the mineral resources of the United States, show, I believe, that the Rocky Mountain States have kept pace with the whole United States in coal production. The actual production in those States has increased from 14 million tons in 1901 to 22 million tons in 1906 and 28 million tons in 1912.

For the sake of clearness and simplicity, a table showing the percentage of total production in each of the four principal fields for the years 1901 to 1912 inclusive is presented:

BITUMINOUS COAL PRODUCTION, IN PERCENTAGE OF TOTAL, OF FOUR PRINCIPAL REGIONS, FOR SIX YEARS PREVIOUS TO ADOPTION OF PRESENT POLICY.

	1901	1902	1903	1904	1905	1906
Appalachian	66.7	66.60	65.64	65.56	67.49	68.10
Eastern Interior	16.6	17.73	18.43	18.55	17.54	17.34
Western Interior	8.7	7.97	8.20	8.34	7.38	6.73
Rocky Mountain	6.2	6.21	6.01	5.85	6.13	6.44

SAME FOR SIX YEARS SUBSEQUENT TO ADOPTION OF PRESENT POLICY

	1907	1908	1909	1910	1911	1912
Appalachian	67.51	65.10	66.26	69.00	67.80	68.30
Eastern Interior	18.13	19.78	18.85	17.41	18.49	18.45
Western Interior	6.80	7.11	6.80	5.24	6.04	5.90
Rocky Mountain	6.06	6.51	6.63	6.92	6.42	6.32

The shifting percentages from year to year in the several fields, apparent in the table, doubtless result from a complex group of conditions, hence it is rash to attribute too much influence to a single factor, such as the growth of corporate holdings, the decreased production of oil in the East as contrasted with the enormously increased production in the West, or the present plan of public coal-land valuation. Yet I venture to suggest that there is no essential difference between the curves for the Rocky Mountains and for the whole country.

Has the Price of Coal Increased Unduly?

Next, as to whether the coal-land valuation policy has raised the price of coal and resulted in hard times in the Western States: I do not recall that my reports have made any specific reference to coal prices, though elsewhere I have expressed my opinion that both now and in the future the consumer is protected by this policy. Here, again, however, it is best to present the available figures, from which anyone may draw his own conclusions. The following table gives the price per ton for the several coal-producing public-land states and the average rate for the United States as a whole, not including Pennsylvania anthracite.

PRICES IN THE PUBLIC COAL-LAND STATES COMPARED WITH THOSE IN THE WHOLE UNITED STATES

	1902	1903	1904	1905	1906	1907	1908	1909	1910	1911	1912
Colorado	1.13	1.23	1.31	1.22	1.28	1.40	1.41	1.33	1.42	1.45	1.49
Idaho	2.50	3.10	3.95	3.03	3.93	4.10	4.02	4.27	3.92	2.68	3.14
Montana	1.65	1.64	1.61	1.72	1.77	1.94	1.96	1.97	1.82	1.79	1.82
New Mexico	1.43	1.37	1.31	1.33	1.34	1.46	1.37	1.29	1.39	1.44	1.42
North Dakota	1.44	1.50	1.43	1.34	1.54	1.61	1.63	1.56	1.49	1.43	1.53
Oregon	2.44	2.43	2.18	2.58	2.66	2.34	2.74	2.69	3.48	2.32	2.60
Utah	1.14	1.20	1.30	1.35	1.36	1.52	1.69	1.66	1.68	1.69	1.67
Washington	1.72	1.69	1.63	1.79	1.80	2.09	2.21	2.54	2.50	2.29	2.39
Wyoming	1.18	1.24	1.30	1.31	1.31	1.56	1.62	1.55	1.55	1.56	1.58
Average for all of U.S.	1.12	1.24	1.10	1.06	1.11	1.14	1.12	1.07	1.12	1.11	1.15

At first glance, the gain in price in 1912 over 1902, or in 1907 over 1906, might seem conclusive proof that classification had increased the sale price of coal in the West. A more careful study of the tables, and of known local conditions of markets and demand and comparison with changes in other fields, however, at once leads to the important query whether this change has been brought about by the change in the public-land policy. For example, in 1902, the price in Colorado, Utah and Wyoming, was from one to six cents above the average for the United States; in 1906, from 17 to 25c. above that average.

Classification Has Not Raised Prices

Classification certainly had nothing whatever to do with this increase in the price of coal. The same tendencies continued to 1912 would have given prices above those of that year. Further, it may be noticed that, in 1907, prices in the Western States jumped above those in 1906, in most cases nearly or quite to the price that they have held since. As 1907 was the year in which the new system was inaugurated, it might be argued that the jump in prices that year over those in 1906 was the direct result of the inauguration of the new system, even though, as a matter of fact, in the year 1907-08, a larger number of coal-land sales were recorded than in any of the previous 5 years.

On the other hand, a knowledge of the coal conditions which existed in the Western states, as well as over the country in general through the first 9 months of that year, I believe will fully account for the increased price, for during those months, as you will remember, the demand for coal ran the price up over the whole country. For example, in his 13th biennial report, the State coal mine inspector of Colorado has this to say:

> The year 1907 was the most flourishing in the history of the coal business, both in the amount of tonnage produced and also in the number of new mines opened and equipped on a scale to meet a large demand for the product; 10,965,640 tons constituted the year's output, and 18 new mines, located in the various districts, were developed by a large expenditure of capital. . . . . During the earlier 9 months of 1907, the demand for all classes and grades of coals was probably the steadiest and best the State has ever known and the prices were exceptionally good. The warning sent out from Washington and by the various railroad companies, recommending the laying in of supplies of coal while they were easily obtained, together with the tide of prosperity increasing the business of all the industries requiring fuel at that time, was responsible for the unusual activity.

I fail to find any hint in the sentences quoted or elsewhere in the report of the mine inspector of Colorado for 1907 and 1908 that the higher prices were in any way due to the inauguration of the present policy of coal-land classification and valuation, and what is true in Colorado I think will be found true in the other states.

In a letter to the Hon. Edward T. Taylor, of Colorado, on this same subject, I stated as follows:

> All the facts before me indicate that changes in coal prices in the public-land states are to be regarded as resulting not directly from any change in Government policy, but rather are controlled directly by the universal law of supply and demand. I have further made the comparison between conditions in the four Rocky Mountain States, New Mexico, Colorado, Wyoming and Montana, and their nearest neighbors on the east, where there are no coal lands in public ownership—Iowa, Kansas, Missouri and Arkansas. These latter States are fairly comparable with the Rocky Mountain States in total production, in general quality of coal, and especially in market conditions, inasmuch as particular markets are in fact served by some States in both groups.
>
> Comparing the output of 1912 with that of the boom year of 1907, I note that in the case of the Rocky Mountain States there has been a considerable increase in production, while in the case of their eastern neighbors there has been a decreased output. In the matter of change in coal prices, each state of the eastern group shows a net advance rang-

ing from 3c. in Arkansas to 18c. in Iowa, the average net advance in the group being 13c. as against 7c. in the six public land States, or even a lowering in price of 5c. if the four Rocky Mountain States are taken alone.

Or, to put it another way, while in the boom year 1907, the average price of coal in the public-land states was 8c. lower than in their nearest eastern neighbors, last year the difference in favor of the public-land states was 14c. So that, as a matter of fact, coal was sold on the average 1 cent lower last year in the public-land states than it averaged in 1907 in the five coal States next east. I am forced to the conclusion that these facts completely refute the assertion that Federal landlordship has forced up the price of coal to the consumer.

I have also approached this same question from another angle. In considering the record of the 8 sales of public coal lands recorded in Colorado in ten months of the past fiscal year, I find that these current sales, though not large in acreage (1320 acres), are in fact sufficient to meet current fuel demands. The Survey is in possession of detailed information resulting from its classification work for seven of these eight entries.

I find that these lands purchased from the Government have a total content of 40 million tons, of which nearly 15 million tons are recoverable and available for mining under present-day conditions, and some 60 per cent. more recoverable, although at considerable depth, and therefore not regarded as now available. Inasmuch as the total mine production of coal in your State last year was less than 11 million tons, these purchases were sufficient to more than offset the current exhaustion of coal lands in private ownership. Moreover, the present holding of coal lands in your State by other than the Federal Government is so large that I would not expect the demand for coal land to be lively.

Administration Has Been Intellectually Honest

In conclusion, permit me to say that the facts to which reference has been made above are simply those which have convinced my associates and myself that the classification and valuation administration of the 1873 coal-land law has proved itself such as serves the people best. In coming to this conclusion, I believe that we have been intellectually honest. Our experience, however, which leads us to defend this policy has also convinced us that this 40-year-old law is far from adequate and that the results we seek can more directly and surely be attained by a lease law.

The Bicknell Explosion

On Dec. 29, 1913, an explosion occurred at the Indian Creek mine of the Bicknell field in the southwestern part of Indiana not far from the Wabash River. It killed only three miners, injured a fourth, and five narrowly escaped death but the explosion was of such a character that had the mine been working in full force the disaster would have measured up with the largest in the past year.

The regular fireboss, it is said, was sick and in his place an old miner went into the mine to make an inspection. He had not gone far when the other men who were working round the shaft heard a small explosion which was followed by a terrific dust explosion, which carried disaster to the top of the 275-ft. shaft. Even the tipple was damaged and some of the mine buildings.

All but the miner who set fire to the gas were swept into the sump below the shaft with a lot of loose timbers and mine cars. Several pumps were put out of commission and it was feared that as a result the men would be drowned. Four men managed to get out of the sump but Alexander Cowen who was pinned down by timbers was rescued only after seven hours had passed. Meanwhile, the water rose rapidly so that his head was but a few inches above its surface when he was rescued. So badly was the stairway in the air shaft destroyed by the explosion that it had to be largely rebuilt before it could be used to remove Cowan. The cage was entirely out of commission and consequently the work of rescue was seriously hampered.

Here's Luck

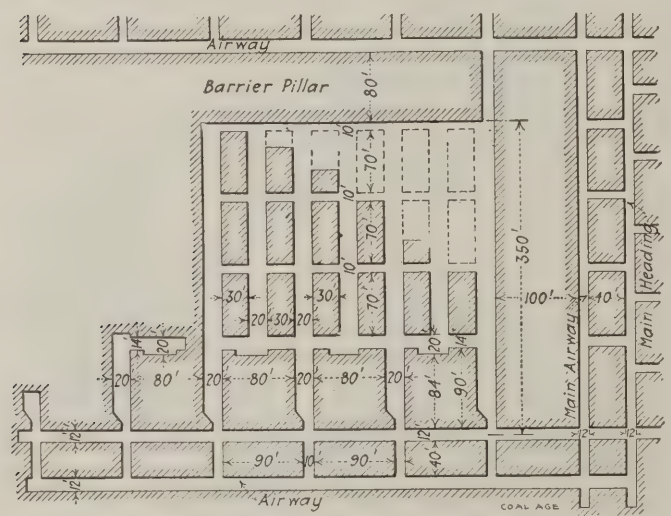
The trembling hand holds up the glass,
Along the bar the catchwords pass—
"Here's luck!"
Flushed faces flush a deeper red;
The whiskey mounting to the head
Stirs phantom hopes where hope is dead;
"Here's luck!"

"Here's luck!" cry those whose luck is blank;
Luck never found the man who drank,
"Here's luck!"
He drinks, and luck has passed along;
It has no place amid the throng
With maudlin burden for their song—
"Here's luck!"

To drink—to drug the active brain,
To make all will, all reason vain—
"Here's luck!"
What fools! Their feet in folly's way,
Carousing through the busy day,
To look within the glass and say,
"Here's luck!"

'Tis pluck wins luck—'twill never come
To those who dull their wits and thrum
"Here's luck!"
Luck? Look where will and reason reign,
Where health nor time is spent in vain;
If such a thing there be 'tis plain,
Here's luck!"

—Wex Jones, in New York "Evening Journal."



Discussion By Readers

Working Coal under Sandstone Cover

Letter No. 11—I was much interested in the recent discussion on this subject, bearing as it did on the recovery of pillar coal, and I desire to submit the following remarks:

In order to obtain the greatest amount of coal when drawing back pillars in the room-and-pillar method of working, the relative width of the rooms and pillars must be determined with reference to the thickness of cover; the nature, thickness and inclination of the seam; the character of the underlying and overlying strata; and the direction of the pillars with reference to the pitch. The length of the rooms as determining the time the pillars must stand should also be carefully considered.

Too small a ratio of width of pillar to width of opening will induce a "creep" or "squeeze." It may happen that the pillars will show no sign of weakness until the work of drawing back a range of pillars is in progress, when the strong sandstone roof will throw an excessive weight on the pillars and crush the coal unless suitable means be adopted to prevent this result.

PROPOSED METHOD UNDER SANDSTONE COVER

In case the entries have been driven to the boundary or limit and the room pillars have been left standing, in order to avoid the possible danger of a squeeze developing when the pillars are drawn, the work should be started at the inby end and proceed outward on the retreating plan. By adopting this method, less loss of coal will result and the cost of maintaining the roadways will be reduced to a minimum while the coal will be obtained in better condition. It is important to keep the line of pillar work uniformly straight and to avoid leaving any stumps of coal in the gob, because these would interfere with the uniform settlement of the overburden and cause trouble. Also, the work must proceed rapidly.

The accompanying sketch suggests a good method of providing ample protection for the main entries and cross-headings while these are being driven to the boundary. As shown in the figure, a flank pillar 100 ft. wide is left to protect the main airway, and a barrier pillar 80 ft. wide is also left between the head of the rooms and the airway above. The cross-heading from which the rooms are turned is protected by entry stumps formed by turning the rooms on 100-ft. centers. These are turned narrow for 5 or 6 yd., and then widened out to 20 ft. As illustrated, a cross-heading is started in the room, at a distance of 90 ft. from the entry. This is turned 14 ft. wide and widened out to 20 ft. on the lower side.

As further shown in the figure, the 80-ft. pillar left between consecutive rooms is then cut by driving a 20-ft. opening or room to the rise of this cross-heading. Crosscuts or breakthroughs are made at suitable distances in the remaining 30-ft. pillars.

This system has given good success in a seam having an average thickness of 4 to 5 ft., the coal being of medium hardness and overlaid with between 200 and 300 ft. of hard sandstone cover immediately above the coal. The seam was underlaid with a fireclay of medium hardness. The pitch of the seam varied from zero to 5 per cent.

Johnstown, Penn.

The Certificate Law

Letter No. 11—The question in reference to the interchange of certificates of competency issued in different states seems to have provoked quite a controversy. The suggestion does not appeal to me that a plan should be adopted by which a mine foreman or fireboss could be granted a certificate that would be recognized in every coal-producing state in the Union.

If a man is qualified to fill one of these positions in Tennessee, Alabama or any other state and desires to hold a similar position elsewhere, he should, in my opinion, be required to work a certain period in the new field, in order to acquaint himself with the existing conditions and the methods employed there to secure greater safety in mining. I regard this as absolutely necessary to make sure that he is not taking risks with the lives of miners that would be under his care.

I am certain that any ambitious man will keep himself posted, sufficiently at least to pass an examination in any state. As far as competency goes, if the candidate for a certificate cannot show that he is qualified by experience as well as by technical education, soberness, morality and truthfulness, he is a dangerous man to put in charge of a mine where he would be responsible for the lives and health of a large number of miners. The best and most competent mining men have accidents, but these are not as frequent as would be if our laws were less strict.

Every tub must stand on its own bottom; so every candidate must show his fitness before he can secure a certificate of competency. Our creed must be: *Safety first, last and always.* Until a man can show himself fit

and worthy to boss a mine, let him handle the pick and shovel and qualify himself by experience and study. Great mine disasters follow each other in such rapid succession, that we hardly recover from the shock of one when we are overwhelmed with the news of another. In my opinion, the solution of this great mystery and problem lies more underground than in the office.

A. H. Stansberry.

Oliver Springs, Tenn.

Letter No. 12—I have been interested in the discussion of the question of the advisability of establishing an interchange of certificates of competency for mine foremen and firebosses, between the different coal-producing states. This seems to me to be a most reasonable proposition and one that I can indorse.

It has been argued that conditions vary widely in the mines in different states, some mines generating gas in dangerous quantities, some having highly inflammable dust, and some seams pitching while others are flat. I would ask, How long would it take a competent experienced man who had his papers of qualification, to acquaint himself with these conditions as they exist? I venture the opinion that, in a short time, he would be master of the situation, because the *principles* of mining are everywhere the same.

It must be remembered that conditions vary widely even in the same state. For example, in Illinois, some mines are worked longwall and others on the room-and-pillar system; some mines generate dangerous quantities of gas while, in others, gas is almost wholly unknown, except for an occasional feeder that causes no alarm. Many of the mines in southern Illinois, particularly Franklin County, are troubled with dangerous quantities of gas and inflammable dust. In some of the mines of the state, the seam is overlaid with a rock roof where a prop is seldom stood. In the same seam, within a few miles there is 42 ft. of soapstone between the coal and the rock, requiring the use of heavy crossbars spaced from 2 to 2½ ft. apart in the entries.

Now, considering this question, with respect to the state of Illinois, the candidate for a certificate of competency is examined as to his knowledge of conditions and methods of mining applicable to the mines of Illinois. The examination may thus often relate to conditions the candidate has never experienced; but he cannot obtain his papers certifying to his competency until he has satisfied the board that he has the required knowledge. A longwall man, having passed this examination, is certified as competent to take charge of a mine worked on the room-and-pillar system. In like manner, men from districts free from gas, but who succeed in passing the examination, are certified as being fitted to hold official positions in mines generating gas. In other words, the scope of the examination is made broad enough to cover all these conditions existing in the state.

I see no reason, therefore, why the requirements in examination cannot be extended to cover the conditions in other states, so that certificates could be granted successful candidates that would be good in any of the coal-producing states in this country. I fail to see why we should be behind Great Britain, in this respect, since the conditions there are as diversified as anywhere in this country.

Compare, for example, the South-Wales coal field with that of the Forest of Dean in England, these two fields being separated by about 20 miles. In the Forest-of-Dean coal field, gas is almost wholly unknown. About 14 years ago, many of the mines in this field were ventilated by furnace. On the other hand, the mines of South Wales give off as much gas as any mines in the world and the dust is highly explosive. Even under these diverse conditions, however, a certificate granted at Bristol, England, has the same force and value as a certificate granted at Cardiff, Wales. In fact, a certificate granted a candidate at an examination anywhere in Great Britain entitles the holder to fill the same position in any coal mine in the United Kingdom. The standard of examination is the same throughout the Kingdom; the subjects are the same, and the candidate must be thoroughly versed in these subjects before he is granted a certificate.

I would argue, therefore, for a universal standard in examination, broad enough to cover all conditions common to coal mining in this country and high enough to secure the required degree of proficiency and insure the safe operation of the mine. On some accounts, the present system of examination and certification is absurd; it is needlessly burdensome and expensive to the state, all of which could be avoided and the system vastly improved by standardization and interstate agreement.

W. L. Morgan,
Ex-State Mine Inspector.

East St. Louis, Ill.

Letter No. 13—A nation-wide certificate or a national certificate law, based upon the conditions assumed in this discussion, in my opinion, would be unjust and productive of harm. Every commonwealth has its own peculiar constitutional formation based upon the physical, social, industrial and political conditions existing within the state. The object of every state constitution is or should be to secure to each individual citizen of the state the inalienable right and privileges to which he is the rightful heir; and to require of him the performance of such duties as the safety and progress of the state demand.

While not an advocate of state rights, in general, I am a strong supporter of state rights in particular. I believe it to be the right and duty of every commonwealth to enact such statutes as will protect its citizens in their vocations and social relations and afford them every facility not inimical to the public good, which they as citizens have a right to demand.

The industry of coal mining has advanced by leaps and bounds, from the class of unskilled labor to a rank among the professions requiring practical and theoretical knowledge and scientific means and methods. Each state has established its own standard of competency based upon its own peculiar conditions, which determine the qualifications required of all candidates for the positions of mine foreman (manager) or fireboss (mine examiner). We may ask, Would not any man who had qualified himself for such position consider it an act of injustice were a citizen of another state permitted to come into competition with him without having first shown his competency by passing the state examination?

I do not regard it as a logical argument to say that the general conditions of mining are so similar in the different states, that when a man is legally qualified in one state, he is like qualified in another state. It would be just as logical to say that a practical miner, who may be as competent to take charge of the mine work as his

foreman but who, lacking the technical knowledge necessary to pass the examination required by law, is not as qualified to assume the responsibilities of the position of mine foreman as a legally certificated man. The certificate granted a successful candidate is the state's seal of approval of the test of his competency.

It is well to observe that the phrase "legally qualified" does not necessarily mean "competent." A candidate is *qualified* if he measures up to the standard of the examination, but *competency* is only determined by the results produced in actual service. The difference in the meaning of these terms is illustrated by the fact that many certified foremen and firebosses, though "legally qualified," are wholly incompetent for the performance of their duties in the mine. This is the result of an unfair examination or the employment of dishonest means and methods to secure the coveted certificate. To broaden the field of operation of such certified men, by a universal certificate law, would unquestionably be productive of harm.

I question the truth of the statement that mine foremen, as a class, have their time so fully occupied as to afford no opportunity for study. Personally, I know this is not true. Too frequently, the certificate is regarded as a guarantee of no further need of study. The rightful possessor of a certificate realizes that it has required effort and sacrifice on his part to obtain the same, and it will require greater effort and sacrifice to maintain its possession. In general, the work of preparation is not as laborious as the later work made necessary by the growing responsibilities of the position. Success in any business or profession is only attained by continually striving.

My judgment is that no qualified or thoroughly competent man would consider it a hardship or an injustice to be required to submit to the standard of examination in another state in which he seeks employment as mine foreman or fireboss.

In this connection, however, I would earnestly urge that every state examination should be open to any citizen of the United States, who should be subject to no other conditions than those of experience and character.

Jerome, Penn.

Working Coal under Watery Strata

Letter No. 1—Replying to the request for suggestions, in reference to working coal under watery strata, Coal Age, Jan. 3, p. 30, I want to say that the conditions described in this inquiry are peculiarly difficult to contend with in the mining of coal.

Unless a suitable method of mining is adopted at the start and the mine laid out in accordance therewith, much trouble is liable to arise from a sudden inflow of water into the mine workings. This is more liable to occur in the winter than in the summer time. It is also absolutely necessary in the development of such a mine, to drive all openings as narrow as possible and to leave ample pillars for the proper support of the overlying strata. In this case, much will depend on the thickness of the fireclay stratum interlaid with the shale and slate immediately above the coal and beneath the water-bearing sandrock.

In dealing with underground water in mining, it is necessary to study closely the character of the strata, in respect to their being pervious to water or otherwise. Under the action of gravity, surface water sinks into the soil and penetrates the underlying rocks to various depths, according to the character and inclination of the strata. Underground water may be considered in respect to two zones. The lower zone being more or less permanent, its upper surface marks what is generally known as the "water level." The saturation of the upper zone depends primarily on climatic conditions, as marked by the wet and dry seasons.

The water level, or upper limit of the permanent zone of saturation underground, in any district, is therefore an important factor in mining. While mine workings lying above this level may only be seriously troubled with water during wet seasons, workings below the water level will generally be subject to a more or less constant flow of water, for which ample provision must be made in the operation of the mine.

In considering rock strata with respect to the flow of water through them, it is observed that the clays and certain massive and igneous rocks are largely or wholly impervious to water, while other strata, such as sandstones, shales and some slates permit, in varying degree, the passage of water through them; and many of these strata absorb and hold large quantities of water.

A coal seam overlaid by a heavy bed of shale free from faults is quite likely to have a dry roof, although the shale itself may be saturated with water held in the pores of the rock. However, if the shale is much broken or traversed by faults or thins out in places and is overlaid with a water-bearing sandstone, there is every possibility of a sudden inflow of water occurring.

Another important effect of underground water that must be considered in mining, is the enormous pressure exerted by the water on the mine roof. Extra caution should be taken to avoid the breaking of the roof, which would be accompanied by an inflow of water. The pressure of the water may even be such as to cause the bottom to heave, in the workings. In all such cases, the work of drawing pillars should be delayed, until such time as the pillars can be drawn rapidly in sections of the mine where ample provisions for drainage are provided. The work of drawing the pillars should, of course, be commenced at the boundary and proceed outward on the retreating system.

I recall an instance, in my own experience, where the roof was broken in the first working, in a mine under conditions such as these. The result was that we had a very wet mine in the winter season, which increased the difficulty of driving the entries. In the summer season, however, the mine was practically dry.

Replying, then, to the questions asked by Mr. MacPhail, I would say that if proper precautions are taken in the development of the mine, there is no doubt in my mind but that 85 per cent. of the coal can be taken out. The amount of coal left in the first working of a mine varies widely under different conditions. The best practice is to leave ample pillars in the first workings in order to minimize the danger from squeeze and inflow of water through the breaking of the roof.

Many of the mines in Pennsylvania are taking out but one-third of the coal in the first workings, leaving two-thirds of the coal as pillars to be taken out later when

drawing back the work, previous to abandoning the mine. Many mines in the Connellsville region of western Pennsylvania take out but one-fifth to one-sixth of the coal in the first workings, driving only narrow stalls and drawing back the wide pillars between them.

It is, therefore, impossible to give exact rules for determining the proper size of pillars to support the overlying strata, as no rule is of universal application, in this regard. Each mine is a special problem that must be studied in the light of successful practice in the same field or in mines worked under similar conditions. Such practice, however, should not be followed blindly. Failure often results from copying the methods employed in other mines, without carefully considering the relative conditions. Because a certain system has worked successfully in one region is no indication that it will be like successful in another. It is of the greatest benefit, however, to study carefully plans that have proved successful and others that have failed.

In my opinion, the same amount of water may be expected in the hoisting shaft to be sunk 300 ft. from the airshaft. Also, the breaking of the roof in different parts of the mine may be expected to result, more or less, in the same inflow of water.

GEORGE STOCKDALE.

Percy, Penn.

Coal Production in Saskatchewan

In the issue of COAL AGE, Jan. 10, p. 67, an article entitled "Foreign Coal Production, Saskatchewan," by Frank B. Smith, states as follows:

> Up to the year 1905 all the published records of coal production in the province were included in the statistics of the Public Works of the North West Territories.

and further on:

> The returns made to the Government in 1905 showed only 60,000 tons mined, but there is no doubt that more coal was produced.

As it might be inferred from these statements that there is still no published record of the production of coal previous to 1905 in that portion of Canada now known as Saskatchewan, I would call attention to the fact that apparently Mr. Smith has overlooked the annual statistical reports of the Canadian Department of Mines. The statistical division of this department has published a record of the production of coal in the territory included within the present boundaries of the Province of Saskatchewan since 1890, these records having been obtained direct from the mine operators. The production for the year 1905 is shown in the report as 107,596 tons.

JOHN MCLEISH,
Chief of Division of Mineral Resources and Statistics.
Ottawa, Canada.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

Effective Depth of Air Column—It has been shown that in all shaft ventilation the effective "head of air column" (D) is the difference in elevation of the top of the upcast and the bottom of the downcast. This applies equally to all forms of natural, furnace or fan ventilation, in shaft mines, where a positive or negative air column may exist.

Likewise, in drift or slope mines, the same law will apply, except where a long slope causes an appreciable rise in the temperature of the downcast air; and in the furnace ventilation of a slope mine. In either of these two cases, three temperatures may be concerned: (1) average upcast temperature in the shaft; (2) average downcast temperature in the slope; (3) outside temperature.

In furnace ventilation, in inclined seams, also, three temperatures must be considered: (1) average temperature of the furnace (upcast) shaft; (2) mine temperature, rise or dip of seam; (3) average downcast temperature. In a few cases, a fourth (4) outside temperature may require consideration. In all cases where more than two temperatures are concerned it is necessary to calculate the column for each separate temperature and corresponding depth and take their algebraic sum.

In practice, the arrangement of the circulation in the mine may be such that the rise or dip column is eliminated by a balance of intake and return columns of equal temperature.

PROBLEMS

Example—A shaft mine, in a level seam, is ventilated by a furnace. The furnace shaft is 900 ft. deep and has an average temperature of 300 deg. F.; the downcast shaft is 600 ft. deep. Calculate the air column producing circulation in this mine and the corresponding ventilating pressure and water gage when the temperature of the outside air is 20 deg. F.

Solution—The effective head of air, in this case, is D = 900 ft. and, assuming that the temperature of the downcast shaft is practically the same as that of the outside air, which is commonly true, the air column, expressed in terms of the downcast air, is

$$h_d = \frac{(T - t)\,D}{460 + T} = \frac{(300 - 20)\,900}{460 + 300} = \frac{280 \times 900}{760} = 331.5\ ft.$$

Expressed in terms of the upcast air the air column, in this mine, is

$$h_u = \frac{(T - t)\,D}{460 + t} = \frac{(300 - 20)\,900}{460 + 20} = \frac{280 \times 900}{480} = 525\ ft.$$

The pressure is found by multiplying either of these air columns by the corresponding weight of downcast or upcast air.

Thus (downcast), $p = \frac{1.3273 \times 30}{460 + 20} \times 331.5 = 27.5\ lb.\ per\ sq.ft.$

Or (upcast), $p = \frac{1.3273 \times 30}{460 + 300} \times 525 = 27.5\ lb.\ per\ sq.ft.$

The corresponding water gage is, then,

w. g. = 27.5 ÷ 5.2 = 5.3 in., nearly

The Coal Age Pocket Book

Example—A slope mine is ventilated by means of a blowing or force fan located at the top of an air shaft 800 ft. deep. The slope is the main return airway and the elevation at its mouth is 275 ft. below that of the top of the air shaft. What natural air column exists, assuming the temperature of the mine is 60 deg. and that of the outside air 10 deg. below zero (— 10° F.); and is this positive or negative?

Solution—The effective head of air, in this case, is D = 800 — 275 = 525 ft.; because the downcast fan shaft has the same temperature as the outside air column, which therefore balances 275 ft. of the shaft column. The downcast air in the shaft being colder and heavier than the upcast or return air in the slope, the resulting air column assists the circulation produced by the fan and is, therefore, a positive air column. It is

$$h_d = \frac{60 - (-10) \times 525}{460 + 60} = \frac{(60 + 10)\,525}{520} = \frac{70 \times 525}{520} = 70.67\ ft.$$

This air column is in terms of the downcast air, which weighs, assuming a barometric pressure B = 30 in.,

$$w_d = \frac{1.3273 \times 30}{460 + (-10)} = \frac{39.819}{450} = 0.0885\ lb.,\ nearly$$

The natural pressure due to this air column is then

$$p_n = 70.67 \times 0.0885 = 6.25\ lb.\ per\ sq.ft.$$

Ques.—If the fan, in this example, were to be reversed so as to exhaust air from the mine, thereby making the slope the intake and the fan shaft the upcast, what air column would result, if the average slope temperature is 40° F.?

Ans.—In this case, three air columns exist, two assisting and one opposing the circulation induced by the fan. They are as follows:

Outside column (*positive*), $w_o = \frac{1.3273 \times 30}{460 - 10} \times 275$

Slope column (*positive*), $w = \frac{1.3273 \times 30}{460 + 40} \times 525$

Shaft column (*negative*), $w_u = \frac{1.3273 \times 30}{460 + 60} \times 800$

The net air column, expressed in terms of say the slope air, is now found by dividing the algebraic sum of these positive (+) and negative (—) columns by the weight of 1 cu.ft. of the slope air, which gives after simplifying,

$$h_s = (460 + 40)\left(\frac{275}{460 - 10} + \frac{525}{460 + 40} - \frac{800}{460 + 60}\right)$$

$$= 500\left(\frac{275}{450} + \frac{525}{500} - \frac{800}{520}\right) = 61.3\ ft.\ (positive)$$

The weight of 1 cu.ft. of slope air is

$$w_s = \frac{1.3273 \times 30}{460 + 40} = \frac{39.819}{500} = 0.0796\ lb.$$

The natural pressure assisting the circulation is then

$$p_n = 61.3 \times 0.0796 = 4.88\ lb.\ per\ sq.ft.$$

Inquiries of General Interest

Ventilation in Airways

It is possible, in the ventilation of a mine, to have the same velocity of air current at the face of the intake entry as at the main entrance? We have been discussing this point and, while one claims that the resistance of the airway would decrease the velocity of the air current, another claims that the volume of air passing the head of the entry must be the same as that entering the mine, providing, of course, there is no leakage of air through the stoppings. It is also claimed that the velocity must remain the same under the same pressure. We are considering a single straight entry having no leakage of air and no butt headings to ventilate.

I want also to ask if it is possible to have more air on the return than on the intake entry in a mine; and how does the warmer temperature of the mine affect the velocity of the air current?

J. H. Frazier.

California, Penn.

Assuming that the sectional area of the entry is the same at the face of the heading as at the main entrance and that there is no change in the temperature of the air, there would be no change in the velocity of the air current.

The *weight of air* passing into the mine, in a given time (pounds per minute), is the same as the weight of air passing out of the mine or the weight of air passing any point in the entries, in the same time. This is true, regardless of the mine resistance.

But, the mine resistance developed in any circulation of air depends on the rubbing surface and the square of the velocity of the air current. This is the total mine resistance or the total resistance of the airway; and the pressure due to this resistance is the pressure per square foot, producing the ciculation. It is the difference of pressure at the mouth of the mine or airway, between the intake and return.

It is important to observe that this difference of pressure between the intake and return decreases regularly from the mouth to the face of the pair of headings, where the difference is zero. The difference of pressure between the intake and return is measured by a water gage placed on a brattice in the crosscut. It is evident that the water-gage reading will be greatest in the first crosscut, at the mouth of the mine, and will be practically zero in the next to the last crosscut, at the face of the heading; but, as stated, the velocity of the air current is constant at all points of the airway, for the same sectional area and temperature.

In answer to the second question: For the same sectional area of the airway, a constant velocity will produce a constant quantity of air in circulation. But any change of temperature will cause a corresponding change in the volume of the air current; and, consequently, a like change in the velocity of the current. As the temperature rises, the air expands in volume. Therefore, the volume of air in circulation varies as the absolute temperature; and, for the same sectional area of the airway, the velocity of the current varies in the same ratio.

For example, a current of 10,000 cu.ft. per min. passing into a mine, at a temperature of 32 deg. F., will be increased on the return airway where the temperature is 70 deg. F., to a volume of

$$10{,}000\,\frac{460+70}{460+32}=\frac{10{,}000\times 530}{492}=10{,}772\ cu.ft.\ per\ min.$$

If the sectional area of the airway remains constant, the velocity will be increased in the same ratio. If the sectional area of the airway is 50 sq.ft., the original velocity is 10,000 ÷ 50 = 200 ft. per min. The increased velocity due to the rise of the temperature is then

$$\frac{200\times 530}{492}=215.44\ ft.\ per\ min.$$

Fan Ventilation

I have recently been studying a difficult problem and have been unable to obtain any satisfactory information from other foremen and superintendents whom I have consulted. Their views mostly contradict my own conclusions.

The situation is as follows: Having charge of a mine that is well developed, and ventilated by a fan that is not large enough to give the required quantity of air, I propose to install another fan on the other side of the mine. Both of these fans will blow air into the mine by separate air courses, the one on the right and the other on the left side of the mine; and the plan is to bring the two currents together into a main-return airway about a mile from the mouth of the mine. In other words, both fans will ventilate separate sections of the mine but use the same return airway for a distance of about a mile, from the working face back to the mouth of the mine.

The question is, will both of these fans work successfully? If you can answer this question, or if some of the readers of Coal Age will give their experience, it will greatly assist me, and I shall appreciate the favor.

D. J. Hopkins,
Foreman, Mine No. 2.

Madera, Penn.

The plan proposed by correspondent is entirely practicable. Both fans being blowers or force fans, there will be no difficulty experienced; but each will perform its proper work. It may be necessary, however, to install a regulator at the inby end of one of these airways or sections of the mine, in order to properly balance the work of the ventilators and secure the proper distribution of the air produced in the two sections.

It is always an error to undertake to run two centrifugal fans in tandem; that is to say, to operate one fan as a blower and the second fan as an exhaust on the same circulation. In that case, one or the other of the two fans will perform the entire work, and the air current will be carried through the other fan by the pressure maintained by the first.

Examination Questions

Selected Fireboss Questions

Ques.—A mine is producing 40,000 cu.ft. of air per min. with 10 hp.; what horsepower will be required to produce 75,000 cu.ft. per min., in the same mine?

Ans.—In any mine or airway, the power producing the circulation varies as the cube of the quantity; in other words, the power ratio is equal to the cube of the quantity ratio. Calling the required power x

$$\frac{x}{10} = \left(\frac{75{,}000}{40{,}000}\right)^3 = \left(\frac{15}{8}\right)^3 = \frac{3375}{512} = 6.59$$

$$x = 10 \times 6.59 = 65.9, \textit{ say } 66 \textit{ hp.}$$

Ques.—With a water gage of 0.4 in., a ventilating fan is making 65 r.p.m. and producing 36,000 cu.ft. of air per min.; what quantity of air will be produced under a water gage of 0.6 in.?

Ans.—The rise in water gage from 0.4 to 0.6 in. may result from an increase in the mine resistance, due to a fall of roof or extension of the airways; or the same rise of water gage may be the result of increasing the power and speed of the fan. The question does not specify the cause of the rise in pressure.

Assuming, first, the power applied to the fan shaft and the efficiency of the fan remain constant, the power on the air will be constant. In this case, the quantity varies inversely as the unit pressure or water gage. In other words, the quantity ratio is equal to the inverse water-gage ratio. Thus, calling the required quantity of air x

$$\frac{x}{36{,}000} = \frac{0.4}{0.6} = \frac{2}{3}$$

$$x = 36{,}000 \times \tfrac{2}{3} = 24{,}000 \textit{ cu.ft. per min.}$$

But assuming, on the other hand, that the rise in water gage is due to an increase of power and a consequent increase in the speed of the fan, the quantity of air in circulation in a given mine or airway will then vary as the square root of the pressure or water gage. In other words, the quantity ratio is equal to the square root of the water-gage ratio. Or,

$$\frac{x}{36{,}000} = \sqrt{\frac{0.6}{0.4}} = \sqrt{1.5} = 1.2247$$

$$x = 36{,}000 \times 1.2247 = \textit{say } 44{,}000 \textit{ cu.ft. per min.}$$

Ques.—The hand on an anemometer turns around 3.25 times in one minute. The airway is 6.25x8.5 ft. What is the velocity of the air current and the quantity of air passing, allowing 3 per cent. for the resistance of the anemometer?

Ans.—The sectional area of the airway is $6.25 \times 8.5 = 53.125$ sq.ft. In the Biram anemometer, one revolution of the large hand corresponds to 100 ft. of air travel, disregarding the error of the instrument. In the given case, the air is traveling at the rate of 325 ft. per min., as indicated by the instrument. Allowing 3 per cent. for resistance, the indicated velocity is 97 per cent. of the actual, which makes the velocity of the air current, in this case, $325 \div 0.97 = 335+$ ft. per min. The volume of air in circulation is then $53.125 \times 335 =$ say 17,800 cu.ft. per min.

Ques.—Where would you expect to find firedamp in a mine?

Ans.—Firedamp may generally be expected to be found in the air current passing the face of a heading or other working place generating a considerable quantity of marsh gas, sufficient to render the passing volume of air inflammable or explosive. Again, firedamp may be expected to be found at the face of a rise heading or chamber that is poorly ventilated, or where the air current is not properly directed so as to sweep the face of the heading. Firedamp also accumulates in pockets or cavities in the roof or other void places not reached by the air current and in all rise workings.

Ques.—If the temperature of the air current passing in a mine is 60 deg. F., and its velocity 300 ft. per min., the sectional area of the airway being 50 sq.ft., what weight of air is traveling per minute?

Ans.—The volume of air passing in this airway is $q = av = 50 \times 300 = 15{,}000$ cu.ft. per min. Assuming a barometric pressure of 30 in., the weight of air passing in this case

$$W = \frac{1.3273 \times 30}{460 + 60} \times 15{,}000 = 1148+ \textit{ lb. per min.}$$

Ques.—What effect does an atmosphere containing explosive gas have on a safety lamp?

Ans.—The effect will depend on the degree of explosiveness of the firedamp mixture and the character of the mixed gases. If the firedamp consists principally of marsh gas and air mixed in such proportion that the mixture has not yet reached the lower explosive point but is merely inflammable, the effect is to cause a disturbed condition of the flame of the lamp, which may reach upward, flutter and become enlarged in volume and finally fill the entire gauze of the lamp.

As more gas is added and the mixture becomes explosive and nears the maximum explosive point, small explosions and sharp cracklings are apt to occur within the lamp when the latter is first introduced into such gas. The moment of greatest danger is when the lamp is being removed from such a mixture of gas and air. The entrance of fresh air into the combustion chamber of the lamp, under these conditions, is apt to cause an explosion within the chimney that will force the flame through the gauze. The lamp should be removed slowly but promptly from such a mixture.

Ques.—Explain, briefly, what is meant by a "dead hole" and what is a "windy shot"?

Ans.—A dead hole is a hole that is drilled more or less perpendicular to the face of the coal and has no opportunity to work so that the charge can free itself. Any shot that is thus bound is spoken of as a "dead hole."

A windy shot is one where the energy of the exploding charge is spent largely on the air, producing a heavy concussion of the atmosphere in the immediate vicinity of the blast.

Coal and Coke News

Washington, D. C.

The Interstate Commerce Commission has handed down a decision in the case of "investigation and suspension docket No. 242" which involves a so called "Chicago switching charge." In this decision a proposed increase in rates on interstate shipments of coal from Chicago, Ill., to Ravenswood, Ill., and the reduction of the amount of absorption on such shipments by line carriers were found not to be justified, and the suspended tariffs were required to be withdrawn. The case in question is another of the series of switching charge cases that have been before the Commission for some time past.

On anthracite coal absorption of the switching charges of the Chicago & Northwestern to both Rose Hill and Ravenswood was provided to the extent of $4 per car, regardless of weight, the difference in rate being the result of the spread in the locals. In an attempted compliance with the order of the Commission, in the case referred to, instead of lowering the Rose Hill rate, the respondents raised the Ravenswood local to 25 cents, and at the same time the line-haul carriers filed tariff canceling the through rate and reducing the absorption on bituminous coal from $6 to $4 per car, the effect of all of which was to put Ravenswood on a basis of 15 cents and 5 cents per net ton higher on bituminous and anthracite respectively, than points immediately south of and in competition with it, by means of wagon and motor-truck deliveries.

In this situation Zipf Brothers Coal Co., located at Ravenswood, protested against the new tariffs becoming effective, alleging that they would result in an illegal discrimination, in that their immediate competitors, of which there were many, would be upon a basis of 15 cents per net ton lower, which would practically eliminate the protestant from the business. It appears that the chief interest of this concern is with the soft-coal rates. Complaint as to the proposed rates was also made by the Chicago Coal Dealers' Association.

"The respondents," says the decision, "seek to justify the manner in which they attempt to comply with the Commission's order in the Rose Hill case by asserting that if they should reduce the Rose Hill rate to within 5 cents of the present Ravenswood rate, it would result in too great a spread between Rose Hill and Rogers Park, and other points immediately north and subject them to the same complaint they encountered in the Rose Hill and the instant case.

This argument, however, is extraneous to the issue, which is whether the proposed rates to Ravenswood are reasonable. The fact that another complaint might possibly arise out of the same general situation is not a controlling factor in the determination of that question, as cases of alleged undue preference or prejudice must be adjudged upon their respective merits.

To substantiate the reasonableness of the advanced rates respondents offer testimony tending to show that what is known as the Chicago switching district really ends at Deering, though the map filed with the Lowrey tariff, to which respondents are parties, indicates that only the inner zone of the switching district terminates at or near Deering while the outer zone extends much farther north and takes in Ravenswood and other points several miles above Ravenswood."

Arguments on Proposed Alaskan Railway

The principal subject of interest during the past week with respect to mining developments has been the discussion of the bill for constructing a government railway in Alaska intended to open up the coal region of that territory as well as to render the copper and gold mining sections of the peninsula more accessible.

Much of the discussion has been of a semi-political type designed to show that the failure to develop the territory by private capital was due to unreadiness on the part of certain capitalistic interests to run counter to the wishes of others which have obtained a strong foothold in Alaska and are in position to defend themselves.

Another large division of the discussion has dealt with purely technical railroad questions, involving the routes that could be followed in reaching the districts that are intended to be opened up. All of this part of the debate has been of purely technical significance. In addition, however, there has been some development of information with regard to the probable effect of the new road upon mining conditions and the circumstances under which freight is now carried and would be carried in the event of the enactment of the legislation.

It is alleged that under existing conditions it costs about $150 per ton to get freight to Fairbanks whereas under the new plan with a Government road it would be not over $27. This is the general drift of the argument in support of the new measure.

HARRISBURG, PENN.

The Interstate Commerce Commission on Jan. 14, resumed its inquiry into the anthracite coal industry with reference to rates and practices existing among the railroads and coal companies. The hearings were begun last November, and were suspended until now, because of the death of Commissioner Marble at Washington, and Commissioner McChord, presided at the present hearing.

The principal questions which the Commission sought to determine by its investigation were:

"Are the carriers directly engaged in the mining and sale of coal, and are these big railroad companies sufficiently separated from the producers?

"Are the rates, rules and practices governing the transportation of coal reasonable?"

According to testimony presented during the hearings, efforts were made to show that the carriers had derived earnings from freights and in return made certain concessions in interest charges, royalties, rentals and in other ways to their own companies, while competitors were forced to pay big freight rates without receiving any concessions whatever.

The interlocking directorates of the Delaware & Hudson R.R. Co., and the Delaware & Hudson Coal Co. it was brought out, were responsible for the attitude taken by the latter company and also dictated its policy toward independent coal companies.

The Reading Co., it was pointed out, owns the capital stock of both the Philadelphia & Reading Coal & Iron Co., and the Philadelphia & Reading Ry. Co., thus forming a holding company and two operating companies. It was also shown that the Reading Co. is financed by $100,000,000 or more of 4 per cent. general mortgage bonds. The holding company also owns $20,000,000 bonds of the Philadelphia & Reading Ry. Co., and the later is obliged to pay 6 per cent. to the holding company, making an additional 2 per cent. The equipment used by the railway company is owned by the Reading Co., and it must pay 8 per cent., which was paid monthly in advance instead of semi-annually in arrears.

The question of interlocking directorates was also touched on in the testimony given by G. H. Ross, vice-president of the Susquehanna Coal Co., which brought out the fact that its subsidiary companies were supposed to pay royalties of from 20 to 28 cents a ton on coal mined on land leased by the railroad to the coal company, but that these royalties had never been paid. That two subsidiary companies of the Susquehanna leased land from the Northern Central R.R. and now owed $6,000,000, but that interest was never paid before 1908, and has been paid since at the rate of from 5 to 6 per cent.

Evidence that the Delaware, Lackawanna & Western R.R. Co., had been lax in its methods of renting property to the Delaware, Lackawanna & Western Coal Co., was obtained from E. E. Loomis, vice-president of the railroad company and president of the coal company. It was brought out that the railroad company is receiving a fair rental for property leased in Buffalo. A quantity of the coal company stock is owned by some of the directors of the railroad it was stated. It was also said that the coal company might have profited to the extent of $112,000 if the coal taken over from the railroad company at the time of the reorganization in 1908 had been purchased by careful inventory of the stored material. A book inventory only was taken, and by this system the coal company lost money on the transaction.

The auditor of the Lackawanna company admitted exchange shipments of coal between his company and the Central Railroad of New Jersey, but that this arrangement was reciprocal, even though contrary to the published traiff rates of the railroad company.

Concerning the storage facilities offered to competitors of the Lackawanna company, it was brought out, that unlimited detention of coal on cars was allowed without demurrage charges to all shippers, but it later developed that the only

shipper having available facilities for free storage of coal on cars is the Delaware, Lackawanna & Western Coal Co., but by pooling their interests, the independent operators might store their product as cheaply as the Lackawanna company.

Testimony on Unpublished Rates

Witnesses were examined with regard to allowances that had been made to companies, and which had not been published in the rates filed with the Commerce Commission. This allowance of from 10 to 15 cents a ton permitted to railroad companies which hauled coal after it reached the trestles and piers to which it was assigned has been stopped recently. This special rate was known as the "Penn Haven rate." The largest allowances were those permitted to the Lehigh Coal & Navigation Co., for its service over the "laterals," which means the special short-cut tracks from the collieries to the nearest railroad center or distributing point. The Lehigh Navigation Co. it was brought out transported much of its coal over these laterals, the allowance to the coal companies on this amounted often to as much as 30 cents a gross ton.

It was brought out by the general coal agent of the Lehigh Coal & Navigation Co., that this company was prevented for many years from entering the Western coal market through hindrance by the Reading Ry. It was also shown that a daily report of all coal, either anthracite or bituminous, transferred to vessels for shipment to New England and other points, is sent to the general sales agent of the Reading Coal & Iron Co., whether the coal belonged to the Reading company or to other shippers.

R. D. Rickard, secretary and treasurer of the New York, Ontario & Western R.R., testified that the Scranton Coal Co., and the Elk Hill Coal & Iron Co., both owned by the Ontario people have been operated in the last few years at a loss and that both concerns failed to pay interest on second mortgages held by the railroad company.

The railroads will have an opportunity to present their side before any decision is handed down by the commission, which adjoined on the 17th, for six or seven weeks, so that the railroads may have an opportunity to prepare their evidence.

PENNSYLVANIA

Anthracite

Harrisburg—It is thought that the next legislature will be asked for an appropriation to establish a safety station similar to the one maintained at Pittsburgh by the United States Government. This request will be the outcome of a recent conference between James E. Roderick, chief of the State Department of Mines, and Dr. Holmes, of the U. S. Bureau of Mines.

Plymouth—The double frame building occupied by Lewis Ryzdewski, located on Vine St., began settling into the workings of the Plymouth Coal Co., on Saturday, Jan. 10, and, on the morning of Jan. 13, had practically disappeared, only the roof being visible from the street.

Wilkes-Barre—Judge Fuller in rendering an opinion for the bench on Jan. 19 established the legality of the 1913 assessment which was attacked by the coal companies. Efforts had been made to set aside this assessment on the ground that it was improperly made, and that the valuation of $250 per foot-acre was unfair and inequitable. The decision in question asserts that the assessment was legally and fairly made, upholds the $250 assessment and leaves no apparent loophole of escape to the coal companies.

Hazleton—The G. B. Markle Coal Co. which has been running a special train between Hazleton and Jeddo for its employees, since the start of the trolley strike in Hazleton, has decided that hereafter the workers must pay five cents each way. The coal company contends that the train is costing $300 a day, and that the miners should defray part of the expenses.

Pittston—One man was killed and two others injured recently by an explosion of gas in No. 17 shaft, Pennsylvania Coal Co. No. 9 Colliery, at Pittston.

Bituminous

Connellsville—The Byrne Coal & Coke Co. recently concluded negotiations for the purchase of the Whyel Coke Co.'s holdings in the Yukon field, aggregating about 100 acres. The purchase price was $70,000, to which $60,000 will be added by the Byrne concern in improvements. The construction of 60 new coke ovens, in addition to the 34 already in place, will be started soon.

Philadelphia—A committee of the Association of Bituminous Coal Operators of Central Pennsylvania is considering the question of bringing damage suits against the United Mine Workers of America as an organization and individually for alleged violations of a contract existing between the operators and the union miners of the central Pennsylvania soft-coal field. Such proceedings, if instituted, would be for the recovery of damages caused by petty strikes in violation of the contract.

Du Bois—It is alleged that the Northwestern Mining and Exchange Co. (an Erie Railroad affiliation) is so disgusted with the attempt of the union to enforce a closed shop that it is preparing to dismantle its Eriton mine near this place. Should this mine be allowed to flood it will be a serious menace to surrounding collieries.

WEST VIRGINIA

Charleston—The Main Island Creek Coal Co., which was recently reorganized at a meeting of the stockholders, will open up a new field in Logan County within the next few months. This firm expects to be shipping coal from six mines by Mar. 1, and from four others in 90 days later. Contracts have been let for the erection of 500 houses, two large storerooms and three power plants of 400 hp. each, which will be completed within the next 30 days.

Wheeling—After a thorough inspection of the mine assisted by J. W. Paull, a U. S. Bureau of Mines' man from Pittsburg, Earl Henry, on Jan. 14 decided that the recent explosion in the mine of the Mound Coal Co. at Moundsville, in which four men were injured, was the result of igniting an accumulation of gas caused by a fall which occurred after the mine fireboss had made his rounds. Aside from the injury to the four men, no damage was done to the mine, which is now in good condition.

Huntington—An important real estate deal was recently consummated at Ironton, Ohio, whereby the Hecla properties passed into the hands of F. B. Enslow, A. B. Brode and Julius L. Anderson, this property consisting of approximately 20,000 acres, a large percentage of which is underlaid with coal, will probably be developed at no remote date.

MARYLAND

Cumberland—The Consolidation Coal Co. has made an opening at mine No. 9, which will develop a new field estimated to contain about 600 acres of coal 3½ ft. thick. The company has completed the outside improvements at the mine and a new haulage system.

KENTUCKY

Whitesburg—It is reported, that since re-opening on Jan. 10, after an extended holiday lay-off, the several large plants of the Consolidation Coal Co. and the Mineral Fuel Co. in the Jenkins, Burdine, McRoberts and Fleming sections, are again operating on full time, in spite of the slow demand for coal in many markets. The shortage of fuel caused by the shutdown has resulted in a good demand from customers of the companies, and large steam contracts have to be filled, regardless of general conditions, which means that the companies will probably continue operations at an active rate, being to a large extent independent of the open market.

Madisonville—Reports indicate that considerable progress is being made by Eastern interests in securing control of undeveloped properties in this section, several deals having been closed recently. Garland Roney, of Providence, Ky., C. H. Murphey, of Madisonville, and others are reported to be interested, and to have made sales lately direct to the interests who are said to be acquiring the property. Nothing is heard, however, of the formerly rumored acquisition of a large number of operating concerns by an Eastern syndicate.

OHIO

Martins Ferry—In line with the recommendations of the State Mining Commission's report to Governor Cox, the Providence Coal Co., with mines at St. Clairsville and Fairpoint, has appointed J. J. Forbes, a mining engineer, as safety inspector. Forbes' duties include the inspection of the mines to prevent possible accidents, the care of the mine-rescue apparatus, and the instruction of the men in accident prevention.

St. Clairsville—About 1000 miners employed in the Blaine and Lansing mines of the Lorain Coal & Dock Co. near St. Clairsville struck because the company refused to haul them into the mines on its mine cars. Under the provisions of the compensation law the company is responsible for injuries to miners while being hauled in that manner and since the men refused to waive their right of action the company refused to permit them to ride on the cars.

Lisbon—Dornacher & Rider, of Akron, Ohio, have purchased 3000 acres of coal lands in Wayne and Washington Townships in Columbiana County which they will develop in the near future.

Coshocton—The Morgan Run Coal & Mining Co., of Cleveland, has closed one of its mines in the Coshocton field permanently, throwing 25 men out of employment. The mine was closed following a visit of the State Mine Inspector D. H. Sullivan who ordered many repairs to insure safety to the miners. The company immediately closed the mine.

INDIANA

Boonville—The increase of stripping operations in the vicinity of Boonville, which have threatened to supplant shaft mining entirely, will meet with opposition in the future, the Central Labor Union of Boonville having adopted resolutions condemning the new method, for presentation to the United Mine Workers of America during the meeting which began Jan. 20. The resolutions point out that the stripping plan is not only detrimental to labor, but that land mined in this manner is completely devastated, and urgently recommend some action to check its further use.

Indianapolis—The Indiana Supreme Court, in a case in which the Shirley Hill Coal Co. was defendant, decides that where a healthy man of 35 years, earning $85 a month, was killed, leaving a wife and five children, a judgment of $8000 will not be held excessive without some showing of wherein the jury was prejudiced or acted with partiality or through corruption.

Dugger—The coal chute of the Sunflower Coal Co. near here was burned, with two cars of coal, Jan. 14. The loss was $6000.

ILLINOIS

Springfield—The Springfield coal Co. has closed three mines, one at Riverton, one at Klondike and one at Taylorville. The Taylorville mine has not been idle before since it was opened up, 25 years ago. The shutdown is indefinite, and all the miners removed their tools from all of the mines. In the aggregate, over 1000 miners are out of work from the three mines. No causes are given, excepting that there is no money in operating a coal mine. It is understood that three other mines of the Springfield Coal Co. will be shut down in the course of perhaps a week.

Pana—The Illinois Midland Coal Co. has filed a mortgage for $3,000,000 in favor of the Continental and Commercial Trust and Savings Bank of Chicago. Several thousand acres of coal rights were transferred this week by the Pawnee Construction Co. to the Illinois Midland Coal Company.

Bloomington—A fire of unknown origin recently destroyed the fan house and blacksmith shop at the McLean County Coal Co.'s mines. The monetary loss will aggregate over $1500, but added to this will be the inconvenience of a forced shutdown while repairs are being made.

West Frankfort—The South mine here recently hoisted 3886 tons of coal in one day. The Zeigler mine a few days earlier hoisted 3401 tons.

Pekin—Factories and railroads are commencing to store coal in anticipation of a strike which is expected when the new scale comes up for consideration and adoption.

OKLAHOMA

McCurtain—The mines of the San Bois Coal Co. will not resume operations until after the expiration of the present contract between the United Mine Workers of America and the Southwestern Interstate Coal Mine Operators' Association.

Poteau—The Claco Mining Co., recently incorporated with $50,000 capital, will shortly develop 260 acres of coal and clay properties, It has advertised for machinery to the value of about $15,000.

TEXAS

Brownwood—A thorough examination of the newly discovered coal field in the eastern part of Brown County has been made, and it is declared that a thick vein of lignite coal of a good quality exists there. The land on which this coal has been found lies along a ridge about 12 miles from Brownwood, and between the towns of Blanket and Zephyr. Leases have been secured on about 1000 acres of this land, and it is planed to start development as soon as possible.

KANSAS

Radley—Two shot firers were killed in Mine No. 48 of the Central Coal & Coke Co. near Radley, Kan., recently. A windy shot caused an explosion, resulting in the death of the men. The bodies were recovered about 12 hours after the exposion.

Mulberry—On Jan. 14 the cable at Mine No. 7 of the Spencer-Newlins Coal Co. broke, dropping the cage, which carried six men about 100 ft. to the bottom of the shaft. Three of the miners upon the cage at the time were killed, and the remainder seriously, if not fatally, injured.

COLORADO

Trinidad—It has been announced from the headquarters of the Colorado Fuel & Iron Co. that the coke ovens at Tercio and Tabasco resumed operations on Jan. 6. The resumption of operations at the coke ovens would signify that a full quota of men is employed at these places, and that the output will be materially increased.

Denver—Nine hundred union miners on Jan. 17 demanded the release within 24 hours of Mother Jones by the military authorities. This demand came from a meeting of strikers at Rockvale, about 900 men being in attendance. The miners affirmed that unless Mother Jones was freed within 24 hours, they would free her by force of arms.

FOREIGN NEWS

Vancouver, B. C.—Interest was recently aroused in Vancouver over the alleged discovery of large coal areas on Smoky River in Alberta, near the British Columbia border along the line of the Grand Trunk Pacific Ry. The coal is said to be a good grade of anthracite similar to that produced in Pennsylvania. The area of the property is 32,000 acres, and is leased at $1 per acre. The leasing company expects to sell the coal in the Prairie Provinces and on the Pacific coast.

PERSONALS

F. J. Harry, M. E. Markell, J. R. Davidson, Charles Detwiler and F. A. Parsons, of Uniontown, were recently elected directors of the Southern Connellsville Coke Co.

J. R. Watkins, Supt. of the Issaquah & Superior Coal Mining Co., after a hard year's work is taking a trip back to Wales. Mr. Watkins expected to sail from New York on the Lusitania on Jan. 14.

Malcolm Macfarlane was recently appointed inspector of mines for the New York Central & Hudson River R.R. Co., with headquarters at Phillisburg, Penn. H. B. Douglas, who formerly held this position, has been assigned to other duties.

R. B. Drum, general superintendent of the Vesta Coal Co., a subsidiary of the Jones & Laughlin Steel Co., with mines at California, Penn., retired Jan. 16 after more than a quarter of a century of service with the company. He was succeeded by H. B. N. Louttit, previously manager of the Monongahela River mine of the Pittsburgh Coal Co.

Charles F. Ice, formerly manager of the Millers' Creek division of the Consolidated Coal Co. in Kentucky, was recently made chief coal inspector for the same firm with duties embracing all divisions. G. M. Gillette, formerly assistant general superintendent of the Elkhorn division, was promoted to be manager of the Millers' Creek division succeeding Mr. Ice.

OBITUARY

L. E. Monser, president of the Wenona Coal Co., and a pioneer operator in the Illinois coal fields, died at his home at Wenona, Ill., recently, after a long illness.

The body of Edward Joyce, who mysteriously disappeared from his home in Carnegie, Penn., in April, 1909, was discovered in some abandoned workings of the Camp Hill mine of the Carnegie Coal Co., on Jan. 14. The portion of the workings where the body was found had been bratticed off from the rest of the mine for several years on account of firedamp. How Joyce, who was boss of the pit at the time of his death came to enter these abandoned workings is unknown, but it is now believed that for some reason he did so and was overcome by the firedamp.

CONSTRUCTION NEWS

Scranton, Penn.—The Pennsylvania Coal Co. is rapidly pushing the erection of its new breaker at Underwood.

Myersdale, Penn.—Men and teams are at work transporting machinery and putting it in place for starting a new coal mine a short distance below the sanitorium power house near this place.

Chillicothe, Ohio—The Norfolk & Western R.R. intends to build a short line about 17 miles in length to penetrate the coal fields of Pike Co., Ky. This branch has been incorporated at Frankfort, Ky., as the Tug River & Kentucky R.R. Co.

Cumbo, W. Va.—In addition to other improvements recently made at the Cumbo yards of the Baltimore & Ohio work has recently been started upon a coal tipple. This structure will be of concrete and its erection is being somewhat impeded at the present time by cold weather.

Pittsburgh, Penn.—The William B. Scaife & Sons Co., of Pittsburgh, Penn., recently received a contract from the Pittsburgh Coal Co. for three steel tipples, each requiring a large amount of structural steel. These tipples are for the Montour mines Nos. 1, 2 and 4.

Lancaster, Penn.—The Philadelphia & Reading R.R. Co. recently awarded to Witmer & Warsel the contract for the erection of concrete and steel coal pockets, office and stable at Lancaster. The work is to be started in the near future and rushed to completion.

Galveston, Tex.—The Atlantic States Coal & Coke Co., a subsidiary of the Clinchfield Fuel Co., has selected Galveston as its headquarters. It is the ultimate intention of the company to locate large storage yards, loading apparatus and a coke-manufacturing plant at Port Bolivar, on Galveston Bay directly across the harbor channel from the Galveston dock.

Bluefield, W. Va.—Large forces of men are engaged along the line of the Norfolk & Western R.R., between Bluefield and Vivian, and work is being pushed rapidly upon the electrification of this section. At the present time construction work is being concentrated to a large extent on the Elkhorn and Maybeury grades. It is now estimated that one year will be required to complete the electrification of the division.

Uniontown, Penn.—Reagan, Lynch & Co., contractors, of Uniontown, have recently completed arrangements for the installation of five Covington coke-drawing machines for the H. C. Frick Coke Co. Three of these machines were erected at the Mammouth works and two at Calumet. The installation of these coke drawers required a large amount of grading, laying of tracks and the reconstruction of the fronts of many ovens. The work was started last September.

Martinsburg, W. Va.—Announcement was recently made that all the rights of way for the new railroad in the Back Creek Valley have been secured and that work will be begun early in the spring. It is not definitely known what route will be followed, two having been surveyed and both being declared to be excellent. The New York syndicate owning the territory has acquired about 30,000 acres of coal land. An analysis of the fuel shows it to be of the best quality.

NEW INCORPORATIONS

Maryland, Tenn.—The Maryland Coal & Coke Co. has been incorporated with a capital stock of $50,000.

Pekin, Ill.—The Champion Coal Co. has been organized with a capital stock of $20,000, to mine and deal in coal. The incorporators are A. L., C. L. and A. P. Champion.

Connellsville, Mo.—The Connellsville Coal & Mining Co. has been incorporated with a capital stock of $15,000. The incorporators are C. W. Evans, Marion C. Miller and S. F. Shoop.

Murray City, Ohio—The Globe Coal Co. has been organized for the purpose of mining and dealing in coal. The capitalization is $10,000, and the incorporators are Vance Webb, Louis Green, E. W. Davis, L. P. Mooney and Arthur Green.

Wellston, Ohio—The Blue Jay Coal Co. has been organized for the purpose of mining and marketing coal. The capital is $10,000, and the incorporators are W. F. McCloud, H. A. Goddars, Grant McGhee, John K. Yeager and G. E. Littler.

Lewiston, W. Va.—The Lewiston Block Coal Co. has been incorporated with a capital stock of $25,000, for the mining of coal. The incorporators are A. A. Starbeury, W. E. Chandler, L. J. Schwartz, Homer Wiseman, and C. W. Morton, all of Charleston, W. Va.

Charleston, W. Va.—The Mill Creek Cannel Mining Co. has been organized to mine coal with a capital stock of $10,000. The incorporators are W. M. Watles, F. G. Campbell and C. Riggs, of Charleston, W. Va., and J. F. Hindson and Fred Watles, of Villa, W. Va.

Carlinville, Ill.—The Elly Coal Co. has filed papers of incorporation. The capital stock is $2,800,000, and the incorporators are Henry C. Hamilton, C. C. Terry, of Girard, and Albert Salzenstein, of Springfield. The company has several thousand acres of coal land in east Macoupin and west Montgomery Counties.

INDUSTRIAL NEWS

Sullivan, Ind.—The mines of the Carlisle Coal & Clay Co. have been sold to the Chicago-Carlisle Coal Co. and will be reopened.

Memphis, Tenn.—The Memphis Coal Briquette Co. is arranging to build a plant with a daily capacity of 200 tons for the manufacture of briquettes. These will be made of West Kentucky slack with a binder of asphaltic material.

Winchester, Ky.—The H. S. Davis Co. on Jan. 15 sold to the Woolf Valley Coal Co. 1270 acres of coal land in Breathitt County near the Perry County line at a private price. Immediate possession will be given and development on a large scale will soon start.

Chicago, Ill.—The O'Gara Coal Co. has given notice that all interest coupons on the bonds of the company due Sept. 1, 1913, will be paid at the office of the company in the Marquette Building, Chicago, on presentation. A few such coupons are still outstanding.

Indianapolis, Ind.—The National Executive Board of the United Mine Workers of America convened here Jan. 16 at the international headquarters to take up the consideration of appeals from the various districts. The business of the board is said to be merely routine.

Henderson, Ky.—The highest price for coal rights said to have been paid in Henderson County up to the present time was $46 per acre recently paid by the People's Mining Co. to W. T. Lambert. J. W. Todd sold about 45 acres of coal rights to the same company for $25 per acre.

Charleroi, Penn.—The H. C. Frick Coke Co. has bought two tracts of coal in Fallowfield Township from W. J. Emery and wife, of Washington. One contained 105½ acres approximately, and the other about 29¾ acres. The price paid was $75,000. This coal adjoins a large tract now held by the Frick Co.

Terre Haute, Ind.—The Illinois Midland Coal Co. has transferred to the Midland Counties Coal Co. 56,500 acres of land and mineral rights, valued at $6,000,000. At the same time record was filed of a sinking-fund mortgage of $3,000,000 upon this property. The land lies in Sangamon and Christian Counties in Illinois and in Otter Creek Township of Vigo County, Indiana.

Springfield, Ill.—The report of Master in Channcery, J. M. Ffeifer on the foreclosure sale of the properties of the Illinois Collieries Co. showed a deficit of $2,983,012.50. The properties were sold Nov. 15 to the Pittsburgh Coal Co. for $126,000. The deficit represents the amount of outstanding bonds, together with interest, and renders certain a total loss of investment to the bondholders.

Drifton, Penn.—Umpire of the Conciliation Board Charles P. Neill recently decided that the action of the Lehigh Valley Coal Co. in cutting the yard price for laying roads from 61 cents to 24 cents in August 1912, and also similarly for moving gob per car, was contrary to the wage agreement. By this decision several thousand dollars back pay will be turned over to contract miners.

Washington, D. C.—According to the testimony before the House Committee on naval affairs of Rear-Admiral R. S. Griffin, the coal taken from the Bering River field in Alaska and tried experimentally by the American navy to determine its fitness for naval uses was a complete failure. Chemically this fuel appeared to be better than the famous Pocahontas coal, but when tested it failed utterly to give the anticipated results. This was extremely disappointing to the officers of the navy.

Mobile, Ala.—The Alabama Fuel & Iron Co., of Birmingham, with mines at Acmar and Margaret on the Central of Georgia, and at Acton on the Louisville & Nashville has opened a Mobile office and appointed Messrs. W. M. and J. F. Johnston, of Mobile as its agents with the idea of entering into the bunkerage business. Contracts have already been signed with the Seeberk Steamship Line, Orr & Laubenheimer Co., fruit importers, and Hubbard-Zemurray Steamship Co., amounting to over 50,000 tons. The coal to be supplied is the Acton, Acmar and Margaret washed nut and slack, all of which is especially suitable for steamship use.

Coal Trade Reviews

General Review

Anthracite much improved by the more seasonable weather, but still lacking the customary snap. Curtailment in mining and further recessions in the bituminous situation. Sharp competition for any spot business that developes. Considerable demurrage coal appearing.

There has been a generally consistent improvement in anthracite all along the line since the recent severe cold snaps. Increased activity is noted in both retail and wholesale business but more particularly in the former. Operations in the mining regions continue on full time, and the fact that the output is being absorbed and some additional picked up from storage piles is indicative of a substantial movement. But all sizes are in free supply, and the customary snap of a mid-winter market is entirely absent.

Curtailment in mining is the salient feature in the bituminous situation. As in anthracite the more seasonable weather has tended to divert attention from the weak spots in the trade; but this has not been sufficiently persistent to hold the market steady, and further recessions are still noted, some spot business being negotiated at lower figures than prevailed at any time in 1913. Demurrage has become a prominent feature in the market, the selling price of occasional tonnages of off quality soft coal often being fixed by the amount of car service against them. Inquiries at the moment are only scattering, and the future market will be greatly influenced by the coming wage conference.

Operations in the Pittsburgh district are still heavily curtailed in spite of an increased domestic demand as a result of the lower temperatures. There is sharp competition for what little spot business developes, and the circular is freely cut. In spite of the determined effort to maintain prices in Ohio the customary winter schedule has finally been reduced to about the usual summer level; business in the spot market is confined entirely to small domestic orders which have developed as a result of the recent change in weather conditions. Contracts for the new year are being negotiated on the same basis as last year with provisions for any change in the mining scale, and method of paying the miners. The circular at Hampton Roads is being well maintained, but the movement is light. The steam demand in the Southern market is somewhat improved, while the colder weather has resulted in an increased movement of the domestic grades, and a general improvement all along the line.

Although the Middlewestern trade is well supplied with coal, the lower temperature has created such an active situation in retail circles that the affects are being felt at the mines. The domestics are notably stronger, while the steam fuels are also showing some improvement. Anticipation of possible labor troubles is already creating a rather tense feeling in some quarters, and a few large steam users have adopted a regular buying program that will provide for an accumulation of surplus stock.

EASTERN MARKET

BOSTON, MASS.

"Opening prices" rumored on Pocahontas and New River as $2.85 plus the possible advance in tolls; but little interest among buyers. Low prices on "market coal" for inland distribution. Anthracite a weather market, with stove the only short size. Disastrous gale on the coast.

Bituminous—Seasonable weather has drawn attention away from the weak spots at Hampton Roads for the time being, and there is beginning to be talk of "opening prices" on Pocahontas and New River. The consensus of opinion seems to be that the f.o.b. basis will be the same as last year, $2.85, unless the much discussed advance in tolls is made, and in that case the advance will be added. There are already rumors of certain pro forma contracts being closed on such an understanding, but it will probably be several weeks at least before there is any significant movement. A good deal will depend on the labor negotiations in the Pennsylvania districts, and it is now rather early to make forecasts.

The question of tolls is a subject of great interest to the New England trade. If coal rates are advanced all over on a percentage basis it is readily seen that it will operate rather against the all-rail shippers into New England and in favor of those who handle Southern coals at tide-water. The general impression is that such a horizontal ruling will probably be the outcome of the present hearings before the Interstate Commerce Commission.

At Providence and Boston cargoes shipped on the market have lately sold down to figures lower than at almost any time in 1913. The demand for coal inland is practically nil.

In Georges Creek and the Pennsylvania grades there is practically no market news. Operations in all the districts are under more or less curtailment and there is only a scattering inquiry. On the quality coals prices are held on a firm basis but that is a matter of policy and not in any way an indication of a better market. The lower priced varieties are heavy and the selling price depends largely on the amount of demurrage that may have accrued and how large a loss the individual shipper cares to sand. All-rail trade is more than listless.

Anthracite—We have now had nearly two weeks of strong coal burning weather and orders are beginning to filter in. Stocks are generally so large however that low temperatures will have to continue for a longer period to develop any considerable demand on the shippers. The companies are still limiting the proportion of stove size in any one cargo but every other size is in easy supply. Dock screenings are scarce on account of the light shipments of domestic coals over the piers.

The Arctic gale early last week worked havoc to shipping along the coast. The property loss is estimated at nearly $1,000,000, six schooners and a barge having been lost.

Current wholesale quotations are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$1.00@1.50	$1.25@1.60	$1.67@1.77	
Philadelphia*	2.25@2.75	2.50@2.85	2.92@3.02	
New York*	2.55@3.05	2.80@3.15	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.80@2.90
Boston†				3.53@3.72
Providence†				3.58@3.72

*F.o.b. †On cars.

NEW YORK

Market continues dull, even the better grades showing the effects of the heavy pressure. Outlook in bituminous indeterminate. Anthracite more active as a result of the colder weather. Mines still working full time.

Bituminous—The soft-coal market has suffered a still further decline during the week, and the pressure is even being felt on the better grades. The good qualities have been in uniformly good demand in the past but occasional reports of weakness are now heard. Considerable coal is on demurrage, and, as usual, the market must be forced in order to find a disposal. As a rule, this is being confined mostly to the off qualities, but, as noted, occasional tonnages of the better grades are heard. It is particularly notable that the market at tidewater continues to lead in the decline; all-rail business is holding up in fair shape, particularly up in the New England district.

But, in spite of the generally depressed conditions, the larger companies maintain an optimistic attitude toward the future market. This may possibly be due to the fact that they are the least sufferers from prevailing conditions as their tonnage is well covered, while many of the smaller concerns are being forced to restrict operations. The outlook is rather indeterminate and dependent on future developments in other lines. Already, a more cheerful feeling is noted in the Western trade as a result of the increased operations in steel.

We quote the New York market weaker but with the price base unchanged as follows: West Virginia steam, $2.60@2.75 good grades of Pennsylvania, $2.75@2.85; best Miller Pennsylvania, $3.10@3.20; George's Creek, $3.15@3.25.

Anthracite—The colder weather of a week ago has had a notably stimulating effect on hard coal. In addition to this, production was more generally curtailed over the holiday period than was anticipated, and there has been a mild rush for certain grades in short supply. All the high-grade buck-

wheats are in good demand as are also pea and egg coal in the domestic sizes. The other prepared grades are inclined to be heavy, particularly stove coal, which is notably long; No. 2 buckwheat in the low grades is rather short, while No. 3 is normal and No. 1 long.

Generally speaking, the domestic grades are all easier, while the steam sizes are strong. The movement out of storage, while improving during the past two weeks, has nevertheless been below normal for the season. All companies report stocks on hand to be larger than normally the case at this season. Some even fear that certain grades will be carried over after the Apr. 1 discount goes into effect.

We quote the New York market on anthracite as follows:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.00	$5.10	$5.05	$5.05
Egg	5.25	5.35	5.30	5.30
Stove	5.25	5.25@5.35	5.30	5.20@5.30
Chestnut	5.50	5.60	5.55	5.45@5.05
Pea	3.50	3.55@3.60	3.50	3.50@3.55
Buckwheat	2.75	2.75	2.70@3.45	2.25@2.70
Rice	2.25	2.25@2.35	1.95@2.20	1.75@2.20
Barley	1.75	1.75@1.80	1.70	1.50@1.70

PHILADELPHIA

Mining continues full but there is a lack of snap. All grades easy and trade needs a sharp rush of orders to clear up stocks. Prompt shipments made to New England.

Trade conditions in this vicinity are at least on a parity with last week. The wholesalers have not found it necessary to curtail mining, which is an indication of improvement, as the market must be absorbing the entire output; but the lack of snap that should characterize the market at this season is still apparent. All the dealers state that the call is not as active as last week, but that considerable coal is moving. As a matter of fact, all sizes seem to be in fairly easy supply. Broken, egg, stove and chestnut, and the smaller sizes are all on a parity, as far as demand is concerned.

The fact that all sizes are moving off would indicate a fairly healthy condition, but what the operators want is a rush that will deplete the stocks, which are reported to be fairly heavy. In spite of the fact that there has been fairly seasonable weather, it will take more than one or two weeks of this to help much. All through the winter there has been no disposition on the part of the trade to place orders ahead for coal. This is doubtless due to the fact that no difficulty has been experienced in securing almost any size required. If the operating companies cannot supply it, the individuals can, and quite frequently at lower prices, either by an absorption of the state tax, or a straight cut from the circular. It is understood that even stove coal, which has held its own pretty well throughout the winter, is being sold at reduction of 25 to 30c. by some of the individuals.

Retail prices continue as follows: Egg, $7; stove, $7.25; chestnut, $7.50; pea, $5.50. Prices at wholesale tidewater still continue as follows: Broken, $4.50@4.75; egg, $4.75@5; stove, $4.75@5; chestnut, $5@5.25. The differentials mark possible concessions on the part of individuals.

It is understood that the anthracite companies shipping coal from tidewater to the New England market are still able to furnish loading for the large fleet of barges engaged in handling this business, but there is no marked activity. It is almost a case of shipping the order as fast as entered, in marked contrast to normal years, when three weeks was considered ample time in which to even expect that an order would be forwarded.

The bituminous situation is characterized as poor, by some operators, but others seem to discern an improvement, as manifested by a better demand, although prices are unchanged. Taking this trade as a whole, however, there is still large room for improvement.

BALTIMORE, MD.

A feeling of confidence in the future of the coal trade. A little more inquiry developing for soft coals, and the anthracite demand is about up to seasonable average now. A number of charters announced.

In spite of all the flat conditions in the present market there is a growing feeling of confidence in the near future of the coal business. Mine interests are going ahead with development plans on the belief that things will soon take a turn for the better in the general industrial situation. The head of one of the largest coal concerns here expressed himself as entirely satisfied that the next two months would see a change for the better.

Prices at present remain at a standstill. West Virginia gas coals run from about 80 to 90c. at the mines, with steam fuels at from 90c. to $1. Pennsylvania fuels of ordinary grade command from 95c. to $1.10, with best grades worth about $1.30.

Hard coal call here is pretty well up to the seasonal average, that is for immediate sales, although the warm winter has made the business as a whole unsatisfactory. Encouragement is found in the announcement of a number of vessel charters for loadings at local piers. Especial activity was shown in foreign charters.

CENTRAL STATES

PITTSBURGH, PENN.

Demand light and production continues at about 50% of capacity. Prices are being freely cut on prompt lots. Connellsville coke demand light, with prices unchanged.

Bituminous—Demand for domestic coal has been somewhat better, as the weather has been seasonably cold, but there has been no increase in demand for railroad or manufacturing purposes, and production continues to average about 50% of capacity in the Pittsburgh district. Outside of the requirements of retail dealers there is hardly any call for prompt coal, shipments being almost exclusively against contracts, and at much less than the normal tonnages involved in such contracts. A few operators are competing rather sharply for the limited orders offered, and regular circular prices are being freely cut in most cases, sometimes to the extent of 10c. or 20c. a ton, except in the case of slack, which is bringing 15c. to 25c. above the circular price. We repeat circular prices as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The market has been quiet, no contracts having been made in the past week, while demand for prompt coke has been quite limited. There are two inquiries in the market respecting contracts, one for delivery beginning February and the other for delivery beginning March, but these are not taken seriously since the buyers had bought for the short period and are rather expected to continue buying from month to month rather than make contracts. Prices are about as well held as formerly, and we quote: Prompt furnace, $1.90; contract furnace, $1.90@2; prompt foundry, $2.40@2.65; contract foundry, $2.40@2.65, per ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ending Jan. 10 at 260,670 tons, an increase of 8519 tons, and shipment at 258,459 tons, an increase of 6308 tons.

BUFFALO, N. Y.

Coal too plentiful for much firmness. More interest now in labor matters than in trade. All reports indicate that a sharp clash is certain. Loading water coal suspended.

Bituminous—The sharp spurts of cold meather are more numerous than formerly, but are of too short duration to give tone to the coal trade, although some dealers find business steadily improving. As a rule, the improvement in demand is slowly increasing, but prices do not advance. There is not now much coal on track here unsold. Dealers have united to some extent and cleaned it up, with the understanding that it should be kept so; as long as there is a car unsold the buyer is in control of the price. There are many reports of shutdowns on account of inability to sell the full output.

The miners are becoming more difficult to manage, and strikes are numerous. Even where mine superintendents strictly observe union rules there are strikes on all sorts of minor differences. The statement made by one of the leading miners' officials that the operators will readily yield to a demand for higher wages, even before the mining year is up, is repudiated by the producers who say they have a surplus of coal, both here and on the upper lakes and do not care if they are idle till June. If the winter is not very severe from now on a long suspension will be welcome.

Some fair prices are still to be obtained for bituminous, in spite of the reports of much cheap coal offering. The highest prices are based on $2.80 for Pittsburgh lump, $2.65 for three-quarter, $2.55 for mine-run and $2.15 for slack. The market for slack is growing steadily firmer. Allegheny Valley coal is about 25c. lower than Pittsburgh.

Coke—There is a little better feeling in the coke market, but it will take some time for prices to advance or even stiffen up to any great extent. The activity of the steel mills is not yet sufficient to create the proper demand for coke. The feeling in iron is better, however, and an improvement is looked for before long. Best Connellsville foundry is quotable at $4.50.

Anthracite—The demand is still light, both locally and for rail-line shipment. The mines are running at a slow rate.

There was at one time a large amount on cars here, but that has been cleaned up. About 50,000 tons was loaded into vessels, and it is now stated that no more will be brought here for water shipment. It is customary to begin loading at least as soon as March if the coal is to be had. Reports from the upper lakes indicate that there will be quite a large surplus on the docks there on May 1, unless the winter is severe. The handlers of independent anthracite are doing very little business.

TORONTO, CANADA

Cold wave has stimulated the market. Steam demand fair but not up to normal.

Coal dealers have been busy as a result of the extremely cold weather. The cold wave was attended by a rush of orders calling for immediate delivery and dealers in many cases were obliged to take on extra help in order to fill them. The demand for soft coal for factory purposes is fair, but not equal to that of last season as manufacturing is quiet. The yards are well supplied, but freight traffic has been congested by the cold snap causing some delay in deliveries. Quotations remain unchanged.

COLUMBUS, OHIO

A new lower circular stimulated buying in steam and domestic sizes. Weather conditions improved and there is a generally better tone to the trade. Wage scale and legislation the main features of interest.

After determined effort to uphold prices for the past two months against adverse conditions, operators and jobbers last week announced a reduction in the circular, placing quotations at the lowest level for several months. This was done in order to steady prices, as cutting was prevelent in all fields. The new level, which is about the same as usually prevail in the summer months, is expected to have a good influence upon trade.

Domestic demand took a brace recently because of the short spell of wintry weather. Dealers put in small orders to replace stocks which were sold at that time. But generally speaking supplies in the hands of retailers are large. It will require considerable cold weather to have any great effect on the trade. Retailers have had a good run of small orders and their teams have been busy.

The steam business showed a little spurt also but is still at a low ebb. A number of manufacturing plants which suspended during the holidays have resumed operations and this means an increased demand for certain grades. Railroads are also taking a large tonnage. As yet manufacturers are doing little toward stocking up to guard against a suspension after Apr. 1. Certain railroads have started their stocking movement. Contracts for steam tonnage are being made at the same figures as last year with provisions for changes in the mining scales and the method of paying miners.

The output during the week averaged about 50 per cent. of normal, due to the slack demand. In the Hocking Valley district the production was about 50 per cent. of the average and the same is true of Pomeroy Bend district. In eastern Ohio and the strictly domestic fields the production was about 40 per cent.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50 @ 1.45	.....	$1.50 @ 1.45	$1.50 @ 1.40
3-4 inch	1.35 @ 1.30	$1.20 @ 1.15	1.35 @ 1.30	1.35 @ 1.25
Nut	1.25 @ 1.20	.....	1.30 @ 1.25	1.25 @ 1.20
Mine-run	1.15 @ 1.10	1.10 @ 1.05	1.15 @ 1.10	1.15 @ 1.10
Nut, pea and slack	0.80 @ 0.75	.....	0.85 @ 0.80	0.80 @ 0.75
Coarse slack	0.70 @ 0.65	1.00 @ 0.95	0.75 @ 0.70	0.70 @ 0.65

DETROIT, MICH.

Considerable coal on demurrage. Market somewhat improved by changed weather conditions but business still slow. Some stocking against a possible suspension in April.

Bituminous—The colder weather over the past week has helped the situation somewhat, but it will have to be of considerable duration before any material benefit will be derived. Prices remain at about the same level, but the movement was somewhat improved, and a generally better tone noticeable. There is said to be approximately 700 cars of consignment coal on track at Detroit, the majority of which is under demurrage anywhere from $1 to $15 per car. Conservatism in mining seems to be the rule, and this will no doubt continue until the surpluses are reduced.

There is an increased demand for the steam grades, also Pocahontas and splint coal. The railroads seem to be in the market for more coal and greater activity is noticeable in general manufacturing. Some stocking against a possible suspension Apr. 1 is also being done.

Mine-run, which ordinarily sells at $1.10@1.20 f.o.b. mines is now readily obtainable at $1; slack is the strong feature at the moment being quoted as high as $1 per ton on occasions.

The market is now quotable on the following basis:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump	$1.65	....	$1.50	....	....	$2.50	$2.50
Egg	1.65	....	1.50	....	....	2.50	2.50
Nut	1.25	....	1.30	....	....	....	....
Steam lump	.25	....	....	....	....	....	....
¾-in. lump	1.10	$1.10	....	$1.00	$1.00	....	....
Mine-run	1.00	1.00	....	1.00	1.00	....	1.25
Slack	1.00	1.05	.80	0.85	0.85	....	....

Anthracite—Indications point to a favorable business this month particularly on domestic sizes.

Coke—Connellsville coke is fairly steady on both contract and spot business. There is little inquiry and scarcely any new business being closed. Local jobbers have accepted as low as $1.90 for contract coke, but the market is more nearly quotable on the basis of $2.

HAMPTON ROADS, VA.

Loadings of coal from Hampton Roads somewhat light both on cargo and bunker vessels. Little demand during week for spot coal. Domestic business improved by colder weather.

Shipments from Hampton Roads during the past week have been somewhat light. This applies to bunker as well as cargo vessels. The greater portion of the coal moving during the week has been on contract business although, of course, there have been some small spot sales. Even with the light demand suppliers are not cutting prices below the circular which has been in effect for some time.

Several cold days during the week has caused a better demand for domestic coals and retailers have had perhaps one of the best week's sales of the winter although they still complain of poor business.

Foreign shipments from Hampton Roads for the week have gone to Montevideo, Kingston, St. Thomas, Port Antonio, Canal Zone, St. Lucia, Para and Manos. Shipments coastwise went to Boston, New Bedford, Providence, Portland, Fall River, Allens Point, and Jacksonville.

The schooner "Grace A. Martin," which sailed from Norfolk, Jan. 4, with a cargo of over 5000 tons of coal for Portland is reported to have foundered Jan. 14 near Martinous Rock. Two of the Palmer schooners which loaded here recently are past due at their destinations and considerable anxiety is felt as to their safety.

LOUISVILLE, KY.

Adverse conditions further intensified by continued mild weather. Heavy stocks on hand. Operations much restricted and prices soft.

Market conditions are practically unchanged although perhaps further intensified by another week of mild weather. Domestic coal is almost unsalable, and the steam market is rapidly reaching the same state. There was promise of some cold weather but the flurry did not last, and was succeeded by the mildest temperatures experienced within the past month or so. In consequence, the demand has since been negligible.

The efforts of the operators to effect sales have been almost wholly without results as the retailers are heavily stocked with coal purchased at bargain prices during the past month; and as the season advances with little demand from domestic consumers, the retailers are naturally disinclined to take on any further supplies. Half-time operations, or less, are in effect at many of the mines, but notwithstanding this, the supply of screenings is inexplicably large.

Prices on all grades have been affected by the conditions indicated, although it is generally recognized that it is futile to make radical cuts. However, orders are eagerly sought, and the few purchasers who are in the market have the trade at their mercy. The better grades of eastern Kentucky block can be had at $1.65 or thereabouts, which sufficiently indicates the state of the market. Nut and slack has held up much better, in comparison with this figure, but is difficult to dispose of, and 65 to 75 cents may fairly be said to represent the range of the market on first-class coal, while the lower grades are freely offered at much less.

KNOXVILLE, TENN.

Colder weather this week has caused a recovery in the market. Notable lack of consignment coal.

The market in this field was completely demoralized by the warm weather which prevailed from Nov. 10 until Christmas day. The New Year opened with coal selling at almost any price that could be secured on domestic, while steam quotations have been sagging since Jan. 1.

During January mines have averaged about four days per week, some less. Operators, however, seem to have gotten over the unprofitable habit of loading and shipping coal for which they had no orders, and little fuel has been reported on consignment this season. This fact has saved the market from a worse condition than prevailed. The cold weather of January has reduced stocks materially, but at present is having strengthening effect on prices.

SOUTHERN AND MIDDLE-WESTERN

BIRMINGHAM, ALA.

Market on domestic coal slightly improved and steam grades also in better demand. No change in blacksmith coal and furnace and foundry coke still quiet. Pig iron shows heavy sales but at slightly lower prices. Car situation fairly satisfactory.

Cool weather for several days has caused a slightly larger demand for domestic lump, though shipments are not what they should be for this time of the year. Steam coal has improved, the demand being much larger from the small users, and shipments on regular contracts increased. The outlook is better on both grades than last week. There is no change in the blacksmith market, prices and demand being about normal.

Furnace and foundry coke show little, if any, improvement, and the prospects are not as encouraging as on coal. Heavy sales of pig iron, amounting to about 125,000 tons, were booked during the week for delivery during the first half of 1914, but the prices were slightly below the $11 per ton basis 2 Foundry f.o.b. Birmingham. The car situation has improved materially, and little trouble is being felt from this source.

NEW ORLEANS

Demand increases due to high price of oil. Better coaling facilities in harbor will cause more steamships to coal at this port. Prospects for year are excellent.

Increasing prices for fuel oil is causing many steam plants in this territory to return to coal. The change of the Kansas City Southern R.R. from oil to coal is certain to have much influence on smaller consumers still using oil. It is stated that a few cents more added to the present price of fuel oil will cause the Southern Pacific to take the same step. This tendency is broadening the market for coal.

Prospects for the year's business are better than has been the case for a decade. The decrease in the use of fuel oil will be the cause of the greatest increase in coal consumption, but the improvement of the coaling facilities in the harbor will mean that many of the lines, not coaling here at present, will do so later. The facilities for loading of coal cargoes here are also likely to be improved, according to the plans of the dock board.

Despite the heavy stocks, orders awaiting the rise in the Ohio are large, while there has been no reduction in the standing orders at the mines in Alabama. With southern Louisiana and Mississippi experiencing the mildest winter in years, the demand for fuel is far below normal.

CHICAGO

Cold weather has a beneficial effect upon market conditions although they are not yet satisfactory. The domestic trade is somewhat stronger and dealers in steam coal are more hopeful. A large amount of steam fuel is being stored in anticipation of a suspension.

Lower temperatures have resulted in an appreciable upturn in general conditions in the Chicago coal market although the situation cannot be characterized as satisfactory. The tone of the domestic trade is stronger with prices remaining firm.

Dealers in steam coal are more optimistic as a result of a slow but steady improvement in manufacturing. Employees of mills and factories laid off before the holiday season are returning to work in large numbers and the consumption of steam fuel has correspondingly increased. Another important factor in the situation is the fear of labor difficulties. This has caused many of the larger consumers of steam coal to adopt a fixed plan of purchasing for storage purposes and the trade has been quick to feel the effect. Market observers express the opinion that there will be serious difficulties and that the present is an opportune time to provide safeguards against a future shortage.

Retail dealers report increased sales of anthracite coal. All-rail shipments are being absorbed more readily although there has been little influence brought to bear on movements from the lake docks. The operators in Franklin County announce that the colder weather has had no appreciable effect upon prices except to check a downward tendency. The better grades of this fuel are commanding $1.75 while other coals sell at prices ranging between $1.50 and $1.65. Prices for Carterville coal remain at about the same level.

There has been some increase in the demand for smokeless coal. A surplus accumulated several days ago because of a curtailment in production and this has been disposed of at prices quoted a week ago. The Hocking market is firmer and dealers believe it will continue to gain strength. The new circular price of $1.75 for 1¼-in. lump, the mines, holds firm. The situation so far as splint coal is concerned shows little change. A large amount of Indiana coal is being stored by steam users and the effect on the market is noticeable in a firmer tone generally.

Prevailing prices at Chicago are:

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic lump	$2.32	$2.55@2.80	$2.27	
Steam lump	1.97		1.97	
Egg		2.55@2.80		$4.30
Mine-run	1.87	2.30	1.87	3.45
Screenings	1.47	1.75@1.85	1.47@1.57	

Harrisburg coal is: Domestic lump and egg, $2.25@2.85; steam lump, $2.25; mine-run, $2.25; screenings, $1.75@1.85; No. 1 nut, $2.55@2.85; No. 2 nut, $2.55.

Carterville quotations are: Lump, egg and No. 1 washed, $2.55@2.85; No. 2 washed, $2.55.

Coke—Connellsville, $5.25@5.50; Wise County, $5@5.25; by-product, egg, stove and nut, $4.90@5; gas house, $4.65@4.75.

INDIANAPOLIS

A touch of cold weather created activity in the retail trade. But it was short-lived and market is back in the rut. Some storing against a shut-down in case operators and miners fail to agree on next wage scale. No transportation troubles. Prices generally fair.

With the temperature around 15° above for a few days the domestic coal trade was benefited, at the yards, but the effect was not felt at the mines. Retailers are well supplied, generally. They seem to have contracted for normal amounts last summer and fall and the winter so far has been mild. They have had no chance therefore to get low in their supplies, for there was always plenty of contract coal ready to fill any holes. The change of weather again dashed the hopes of dealers who anticipated a stretch of real winter.

Mine operations show little change. What little activity there is, comes from large consumers who do not care to risk a shut-down of the mines on Apr. 1 and in consequence are increasing their stores of coal. There is little if any complaint of handling of the coal by the railroads. Conditions have improved greatly in this respect over those prevailing in October and November.

Prevailing prices at the mines are $1.10 for No. 4 mine run, $1.25 for steam lump and nut; $1.45 for egg; $1.70 for domestic lump and 80c. for screenings. Contract business is slightly higher and coal in the open market can be had slightly lower than these figures. Screenings continue scarce and prices stiff while some bargains are reported in mine-run and domestic lump. There is no demoralization, however, and prices are well maintained, taking the Indiana field as a whole.

ST. LOUIS, MO.

Demand for domestic grades poor, due to mild weather. Situation now hinges on the coming labor conference.

Continued warm weather has broken down the market, and there is absolutely no demand at all for domestic sizes and the steam sizes weakening. There is something radically wrong with local conditions, but the trade seem unable to solve the problem; with no demand for lump and egg there seems to be a tonnage of the small sizes, sufficiently large to take care of the demand, and for the past week the screenings market has been gradually dropping.

It is the same thing with everything else; anthracite, coke and smokeless are slower now than in the month of March, which is usually the dullest in the year. There seems to be no relief in sight, unless it is cold weather, and the trade has about given up hope of seeing any real winter.

If the conferences between the miners and operators bring about any indication of a suspension or a strike in April, it will materially improve conditions, but if a settlement seems probable the situation will likely become worse.

The prevailing market is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump	.....	.....	.....	$0.90@1.00
3-in. lump	.....	.....	$1.40	.....
6-in. lump	$1.25 @ 1.50	$2.25	1.50	1.15@1.25
Lump and egg	1.85 @ 2.15	.....	.....	.....
No. 1 nut	1.15 @ 1.40	.....	.....	.....
Screenings	0.75 @ 0.80	.....	.....	.....
Mine-run	1.10 @ 1.20	.....	.....	.....
No. 1 washed nut	1.60 @ 1.75	2.25	1.60	.....
No. 2 washed nut	1.25 @ 1.35	.....	1.25	.....
No. 3 washed nut	1.15	.....	.....	.....
No. 4 washed nut	1.05	.....	.....	.....
No. 5 washed nut	0.50	.....	.....	.....

KANSAS CITY, MO.

Demand light due to unseasonable weather. Mining much curtailed. Market steady but weak.

Lack of a continuous stretch of cold weather has prevented operators of Kansas and Missouri from getting much beyond half time in the mines. The weather has been variable, and has not provided any great amount of business for the mines. The latter have depended chiefly on contracts from railroads and other big consumers to keep them busy, and have worked about half time without difficulty. The Pittsburg district could not have turned out more than half its capacity even if demand were strong because of an accident. Demand for domestic purposes has been light. The market has been steady and rather weak, though no pronounced change was noted in this respect.

PORTLAND, ORE.

Portland investigating the cost of fuel for bunkering purposes. Market unusually quiet as a result of the warm weather.

At its regular monthly meeting here last week the Port of Portland Commission instructed its manager, M. Talbot, to communicate with the various coal-producing districts and ascertain the cost of laying down coal in Portland. It is expected there will be a much heavier demand here upon the completion of the Panama Canal and the establishment of many new steamship lines and it is desired to be in position to furnish them with coal here as well as at other Pacific Coast ports.

So far the winter has been unusually mild here and in the entire Pacific Northwest and there has been no occasion for advanced prices. While some cold weather may be experienced, it is not likely that it will be of long duration.

PRODUCTION AND TRANSPORTATION STATISTICS

NORFOLK & WESTERN R.R.

The following is a statement of tonnages shipped over this road from mines in West Virginia and the commercial and company coal, for the month of December, in short tons:

Field	Shipped	Tipple	Total	Commercial	Company
Pocahontas	930,212	18,276	948,488	934,600	107,910
Tug River	220,746	3,050	223,796	162,666	61,130
Thacker	234,752	8,885	243,637	156,834	86,803
Kenova	78,518	9,199	87,717	70,043	17,674
Clinch Valley	.....	.....	.....	125,324	14,135
Other N. & W.	.....	.....	.....	36,848	.....
Total N. & W. Fields				1,486,315	287,652
Williamson and Pond Crk. RR.	.....	.....	.....	50,926	10,930
All Othe Railroads	.....	.....	.....	74,128	.....
Grand Total	1,464,228	39,410	1,503,638	1,611,369	298,582

Total shipments of coke, entirely from the Pocahontas field amounted to 85,846 tons.

CHESAPEAKE & OHIO RY.

The following is a comparative statement of the coal and coke traffic from the New River, Kanawha and Kentucky districts for November and the five months ending Nov. 30, 1912 and 13, in short tons:

	November		5 Months			
Destination	1913	1912	1913	%	1912	%
Tidewater	255,344	252,447	1,313,390	17	1,466,758	22
East	248,297	311,684	1,029,925	13	963,386	14
West	289,521	731,129	4,831,363	63	4,222,603	61
Total	1,395,162	1,195,216	7,174,678		6,652,747	
From connections						
Bituminous	133,599	69,230	561,420	7	175,687	2
Anthracite	1,225	1,198	7,689		5,430	1
Total	1,529,986	1,265,688	7,743,787	100	6,833,864	100
Coke	28,535	24,216	147,818		131,392	

FOREIGN MARKETS

GREAT BRITAIN

Jan. 9—Business in large coals shows more activity, but the demand is principally confined to prompt positions. Buyers continue to hold back inquiries for ahead shipments in the hope of being able to secure easier terms. Small coals are plentiful and the tendency is irregular. Quotations are approximately as follows:

Best Welsh steam	$4.62@4.74	Best Monmouthshires	$4.26@4.32
Best seconds	4.44@4.56	Seconds	4.02@4.14
Seconds	4.32@4.44	Best Cardiff smalls	2.64@2.70
Best dry coals	4.56@4.68	Seconds	2.40@2.52

The prices for Cardiff coal are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both net, exclusive of wharfage, and for cash in 30 days.

British Exports—The following is a comparative statement of British exports for December and the 12 months of the last three years, in long tons:

	December		12 Months		
	1912	1913	1911	1912	1913
Anthracite	230,803	249,496	2,454,523	2,547,712	2,976,389
Steam	4,210,920	4,4,88444	47,119,017	46,539,374	53,619,022
Gas	829,435	980,548	10,504,172	10,559,845	11,527,586
Household	141,763	134,348	1,540,710	1,639,571	1,769,571
Other sorts	284,447	276,581	2,980,844	3,157,893	3,507,402
Total	5,,697,368	6,229,453	64,599,226	64,444,395	73,400,118
Coke	97,409	118,619	1,059,876	1,059,650	1,223,936
Manufactured fuel	171,400	178,235	1,612,741	1,580,803	2,053,187
Grand total	5,966,177	6,526,307	67,271,883	67,035,848	76,687,241
Bunker coal	1,556,784	1,842,006	.....	18,291,370	21,031,507

GERMANY

The German coal production for November and the 11 months and imports and exports for November were as follows:

	Imports		Exports	
	1912	1913	1912	1913
Coal	1,002,271	910,433	2,551,839	2,879,752
Lignite	676,065	508,817	5,629	5,550
Coke	50,130	35,203	505,844	402,090
Coal briquettes	5,167	1,759	168,123	116,041
Lignite briquettes	16,276	9,483	73,885	61,140

	Production			
	November		11 Months	
	1912	1913	1912	1913

Westinghouse Motors For Moderate Sized Hoists

While manufacturing the electrical apparatus for the largest mine hoist installation ever undertaken in the United States, the Westinghouse Electric and Manufacturing Company has devoted very careful attention to the design of motors for moderate sized hoists.

No attempt is made to take motors designed for some other purpose and adapt them to mine conditions. **They are hoist motors and are especially designed in every respect for this service.**

These motors have unusually heavy pulling power for their horsepower rating. The revolving part is small in diameter to permit quick stops and reversals. Low power consumption insures economical operation.

They are particularly designed to allow ease of inspection and dismantling, if necessary. All coils are form wound and placed in open slots, making repairs, in case of accident, as simple as possible.

Our nearest office will be pleased to furnish full information about Westinghouse Mine Hoist Motors upon request.

VOLUME 5 JANUARY 31, 1914 NUMBER 5

CONTENTS

WITH PRINCIPAL ARTICLES SUMMARIZED

*Illustrated Article

FOREWORD: *Page* 191

The Question. Some verses dealing with the important subject of decently and properly providing for the older employees who have spent the best part of their lives serving in minor positions. Berton Braley. COAL AGE, Vol. 5.

IT IS BETTER TO ELIMINATE A WRONG THAN TO ALLEVIATE THE EVIL CONSEQUENCES: *Page* 192

*SAFETY LADDER FEET FOR CONCRETE AND IRON FLOORS: *Page* 192

*MINE FIRES ON AN EXPERIMENTAL SCALE: *Page* 193

*A WIRELESS SYSTEM OF TELEPHONY FOR COAL MINES: *Pages* 194-195

Reineke's wireless telephone system dispenses with all connecting wires and has been used successfully for two years in a Westphalian colliery. It can be readily moved from one place to another and is not affected by other electric currents. No sparks can be produced. COAL AGE, Vol. 5.

AN ANALYSIS OF THE OHIO MINING COMMISSION'S REPORT: *Pages* 196-200

The second and concluding article on the Ohio Mining Commission's Report. The arguments of both the miners and operators for and against the proposed new legislation are discussed in detail. The main contention of the miners appears to be founded on an intangible psychological condition. A. T. Shurick. COAL AGE, Vol. 5.

*A FLOAT-AND-SINK TEST DIAGRAM: *Page* 201

THE GASES IN COAL: *Pages* 202-203

WHO'S WHO IN COAL MINING: *Pages* 204-205

A brief sketch of the life of H. M. Wilson, chief engineer, Bureau of Mines, Pittsburgh, Penn.

EXAMINATION QUESTIONS WITH ANSWERS: *Page* 220

COAL AND COKE NEWS: *Pages* 221-224

A SAFETY BANQUET IN WEST VIRGINIA: *Pages* 205-206

The United States Coal & Coke Co. gives its fourth annual safety-boosting banquet to its employees. This banquet is one of the many plans this firm employs to foster the safety morale of its working force. COAL AGE, Vol. 5.

*THE TRANSITION FROM INFLAMMATION TO EXPLOSION OF COAL DUST: *Pages* 207-210

An explosion is not merely a culmination of progressive combustion, but a suddenly developed phenomenon when the coal as a whole enters into chemical reaction and would so act, even if it did not contain any hydrocarbons. This develops such a center of force that a wave of pressure backs on the zone of inflammation, producing those effects previously ascribed by most writers to suction. COAL AGE, Vol. 5.

EDITORIALS: *Pages* 211-212

One Way To Save Time

The Weekly Ad-Talk Page

"In this terrific, ceaseless, relentless strife, methods—ideas—are the arms and equipment, as sword and breastplate were the weapons of ancient Greek and Roman, as battle-axe and plate armor were the equipment of the Crusader. And as no nation today would think of going to war with obsolete equipment, so no business man can succeed unless new, advanced ideas are shield and buckler. One modern battleship would blow all the navies of antiquity out of the water. Similarly, there are methods for doing business, born of yesterday's ideas, which make the methods of a few years ago seem ludicrous."

The above is from an able editorial in "System"—the progressive magazine for business men.

We quote it here because the sentiment of the writer applies equally to you in the field of coal mining.

There are methods for accomplishing things in the coal mine that enable the up-to-the-minute engineer, the engineer who takes advantage of the new ways of doing things, to make the results from old-time equipment look sick.

And how are you going to keep constant track of the new things coming out and being developed in your field unless you keep in constant touch with the manufacturers in your field?

And what better way to keep in constant touch than by reading the business messages of these manufacturers in the Selling Section in issue after issue of your technical paper?

In the Selling Section of COAL AGE you find the manufacturer's explanations of why you can use his goods to advantage.

You can find the pump manufacturers quickly—the hoist builders, the drill manufacturers, the manufacturers of all kinds of mining equipment and supplies.

You do not have to weed through a mass of advertising material that is not in your field.

The advertising pages contain only advertisements of coal mining equipment and material—the kind of advertising that gives you the ideas that help you produce salary-raising results.

The Selling Section, in other words, is a business education for the mining man—the finest kind of a guide when he needs anything for his plant.

Advertising is today's method of bringing the best of manufactured goods to the doors of the men who can be materially benefited by the use of those goods.

And the man who takes advantage of the ideas the advertising pages hold out is naturally the man who is able to show the best results, the most improvement in the year's efficiency figures.

Make the Selling Section help you week after week.

* * * * *

Only good goods can be continuously advertised.

COAL AGE

Vol. 5 NEW YORK, JANUARY 31, 1914 No. 5

The Question

By Berton Braley

Written expressly for Coal Age.

What have you done with the old men
  Who're broken by toil and time?
Once they were brave and bold men,
  Now they are past their prime,
Now they are aged and juiceless,
  Now that their race is run,
Now that they're weak and useless,
  Tell us: What have you done?

Have you made their hard lives rougher
  By turning them out, in truth,
To shiver and starve and suffer
  In the world that was meant for Youth?
Now that they cannot aid you
  Nor earn their miner's wage,
For all that their work has paid you,
  How have you dealt with Age?

Once they were young and gay men
  Toiling to make you wealth,
Now they are bent and gray men
  Broken in strength and health,
Have you pensioned these one-time bold men
  Or starved them as some men do?
As you have dealt with the Old Men
  May Destiny deal with you!

It Is Better to Eliminate a Wrong Than to Alleviate the Evil Consequences

Yes, Mr. Superintendent, the Christmas and New Year season is past and you have again settled down to your ordinary way of doing things. Probably by now that feeling of benevolence stirred up in you by the sound of Christmas bells has passed away, or is rapidly disappearing. You have probably helped charities both worthy and unworthy during the past month.

Maybe you gave John Brown's orphans a dollar apiece and provided them with a few toys; also, if the feeling was strong upon you, you saw that they had their Christmas dinner.

Perhaps you also assisted Bill Thompson's children whose sufferings were caused by Bill's foolish desire for drink. What a time you had at the Christmas tree! and how glad you were to see parents and children all happy.

You did feel sorry for Henry Williams and his wife who were there, but all alone, the sweet little boy and girl they were blessed with having been snatched away from them by the "Grim Reaper," during the epidemic of fever which swept the camp last spring. But while you in your benevolence attempted to alleviate some of the misery around you, did you pause to think of what had actually caused some of it ?

Maybe if you sit down now and consider, you will discover that your mite just expended in the cause of charity did not compensate for your being responsible for much of the misery which aroused your sympathy.

Had you paid more attention to the various "Safety Movements" and not displayed such criminal indifference to the social conditions of your workmen, perhaps some of the misery which touched your pity would not have existed.

Perhaps You Are Responsible for Much Misery

You are probably indirectly responsible for the conditions of some of those poor sufferers.

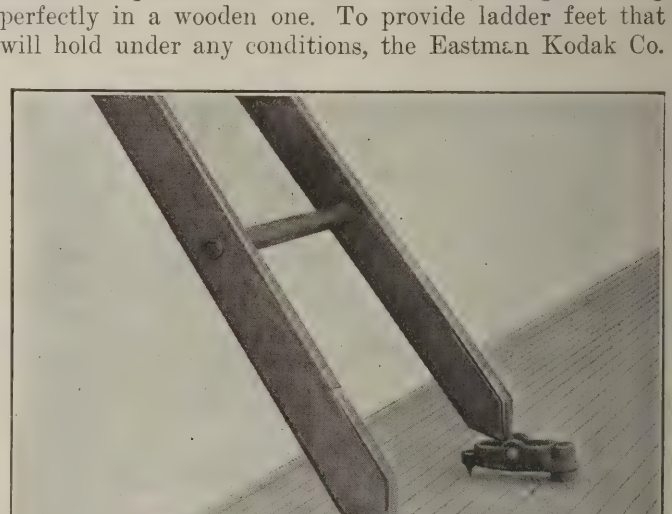
Why did you not have some of your men trained in first-aid work? Then John Brown would not have died from arterial bleeding, for his wounds would have been instantly attended to. And maybe William Thomas, whom we omitted to mention before, would have had two legs instead of only one, if he had not been roughly and unskillfully handled by untrained men.

In both cases the children depending on these men would have been able to enjoy more luxuries than they did, even without your paltry dollar or two.

You also maintain a very nice (?) saloon in your camp, and while the houses you provided for your workmen were as plainly and poorly built as possible, this same liquor emporium is fitted up with all the modern attractions of such abodes of corruption. The human desire for things better than we ourselves possess probably attracted Bill Thomson first to such a place, hence his downfall.

Your camp is in a bad sanitary condition and has been so for some considerable time. You know this is true, and you also know the reason for the outbreak of fever which took away Mr. and Mrs. Henry Williams' children. However, you excuse yourself on the plea of "saving expenses."

Why Do You Not Take an Interest?



Why do you not take an interest in the safety-first movements and maintain efficiently trained corps with all the necessary appliances? Why do you not take an interest in the social welfare of your workmen and keep your camp in good shape? Also, why do you not assist the promotion of such societies as the Y. M. C. A. in your camp? Surely it cannot be that you have no time to consider anything other than the making of a few paltry dollars to improve your reputation for cheapness of production, regardless of the fact that you are gambling away human lives.

If low cost of production is your only thought, it is time you were eliminated. Get down to business and remember there are more days than Christmas Day and New Year's Day to do good.

Pay a little more attention to the human element and then you will be fit to hand out a dollar along with a Christmas blessing to a worthy cause. If you are responsible for so many miseries, due entirely to your indifference and negligence, you are as guilty of murder as if you had deliberately shot your victims.

Safety Ladder Feet for Concrete and Iron Floors

Often a ladder equipped with sharp-pointed or spiked feet will slip on a concrete or iron floor, though holding perfectly in a wooden one. To provide ladder feet that will hold under any conditions, the Eastman Kodak Co.

Safety Feet for Ladder

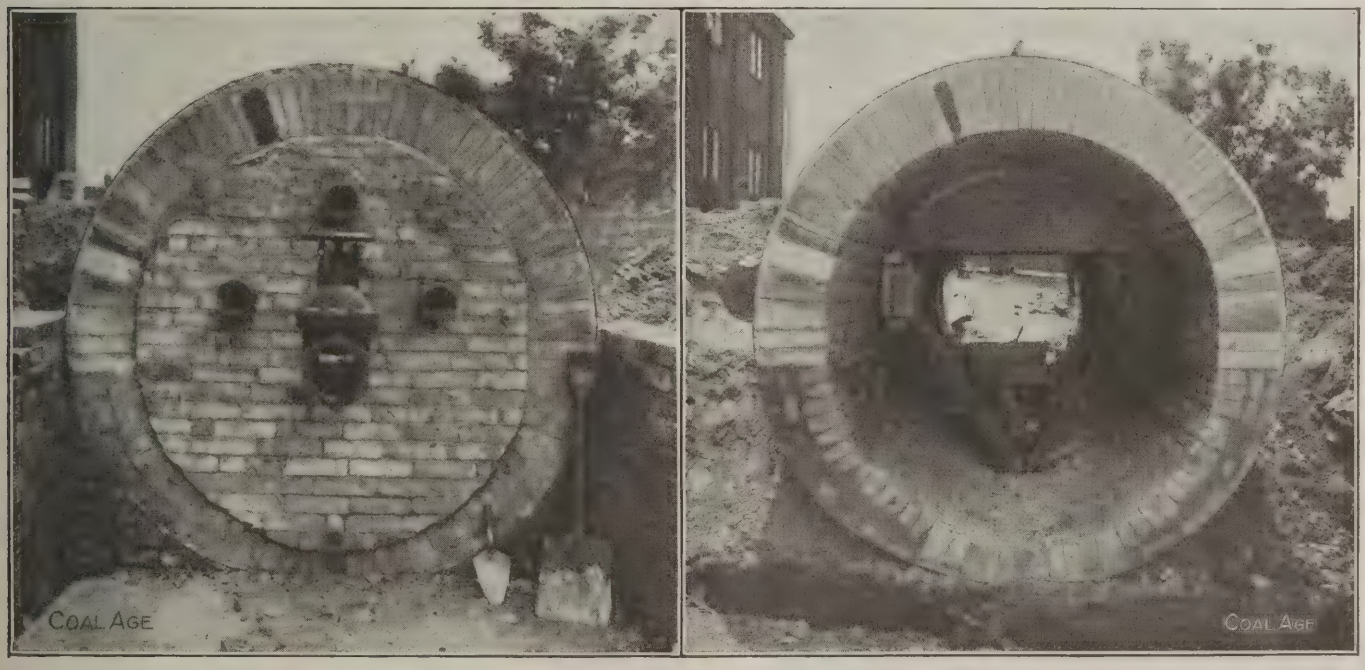
has designed the style shown in the illustration, taken from the *American Machinist*. This consists of castings hinged to the ladder legs as shown. Each casting carries a spike at one end and a rubber pad at the other. The spike will hold on wood or dirt surfaces, and the rubber on surfaces where the spikes would slip; the two make an ideal combination that needs no adjusting when setting the ladder. The spikes used are threaded horseshoe calks of a type easily purchased in the open market, and the rubber pads are standard large-size crutch tips.

The number of ladder accidents have caused much ingenuity to be displayed in their reduction. The American

Mason Safety Tread Co., of Lowell, Mass., is using carborundum grains set in delta metal casings for ladder footings. The carborundum retains its edges and even when the false ladder foot becomes coated with oil or grease, it still retains reliable nonslipping qualities.

Mine Fires on an Experimental Scale

The Bureau of Mines has recently installed at its Pittsburgh experiment station an underground chamber or furnace in which to carry on experiments relating to mine fires and spontaneous combustion as occurring in mines.



A section of steel tube, cylindrical in shape, 6½ ft. in diameter and 27 ft. long, was laid on its side in a trench. After lining with firebrick and mineral wool and stopping the ends with 13-in. brick walls, this shell was covered with two feet of earth. The chamber was constructed so as to be as nearly airtight as possible, and in such manner as to retain to the greatest degree practical any heat generated within its walls.

General View of Plant

The progressive changes in composition of the fire gases or of the air surrounding the coal will be followed and temperature measurements made, in an endeavor to apply the data thus obtained to solving practical problems in the treatment of mine fires.

Investigations have been made in other countries and to some extent also here, on the gases produced in actual cases of mine fires both before and after sealing off a burning area. The bureau is now making, however, probably the first attempt to investigate such problems in an experimental apparatus which permits careful control of conditions and yet is on a scale nearly commensurate with mining operations. These experiments are being carried on by Horace C. Porter, chemist, of the Bureau of Mines.

The Steel Cylinder Lined with Firebrick and with End Bricked in

At one end a motor-driven fan will blow in air at a rate which can be accurately measured, and at the other a stack is provided which can be opened or closed as desired. Through the top of the chamber, at frequent intervals, pass small pipes for withdrawing samples of air or gases and for inserting pyrometers for temperature measurement in the interior.

Coal and Waste Material Will Be Scientifically Tested

The chamber will hold 6 to 8 tons of coal when one-third full. It is expected that different kinds of coal or of the gob or waste material from mines will be placed in the chamber and a study made of the spontaneous development of heat in them under various conditions. After an active fire has been started either by this means or artificially, experiments will be made on controlling it by reducing the air supply or by sealing it off entirely.

Messrs. Fletcher, Burrows & Co., colliery proprietors, of Atherton, England, have just completed the erection of a lofty and spacious building containing 40 spray baths for the use of the 700 colliers employed at their Gibfield pit. The water for the baths is supplied from a large tank inside the building capable of holding 500 gal. of water. The collier, after taking off his pit clothes, goes into one of the small recesses, and pressing on a piece of wood with his foot causes the water to come over him in the form of a spray at a temperature of 96 deg. Seven minutes are allowed for the bath, and the collier has to bring his own soap and towel. After rubbing himself down, he can put on his clean walking clothes, which have been slung up to the ceiling, and if they have been in the rain, will be quite dry by the time he needs them. There are 396 of these slings, each numbered and provided with a separate lock and key.

A Wireless System of Telephony for Coal Mines

Special Correspondence

SYNOPSIS—Reineke's wireless-telephone system dispenses with all connecting wires and has been used successfully for two years in a Westphalian colliery. It can be readily moved from one place to another and is not affected by other electric currents. No sparks can be produced.

The liability of the connecting wires in ordinary mine-telephone systems to become damaged and broken by the work going on in the colliery has always been a source of trouble, and, from time to time, attempts have been made to provide a satisfactory substitute to the ordinary telephone service, or to so improve such service as to make it absolutely beyond suspicion in the above respect. With the advent of wireless or spark telegraphy for ordinary above-ground work, it was confidently hoped that developments would shortly occur in connection with the application of the same means of transmitting electrical impulses and telephony in mines, but there are certain disadvantages with regard to spark telephony which make it difficult of application to this purpose.

Means, however, of dispensing with connecting wires have been developed by Reineke's Wireless Telephones, Ltd., of London, and Herr Reineke's system has been in regular use for two years in the Carolinengluck mine, at Bochum, in Westphalia, Germany. No other system of signaling is now used. Since then it has been applied in Great Britain at the Dinnington Main colliery, and Fig. 1 shows the manager of this colliery at the receiving and transmitting station in his office underground. The second illustration shows the engineer of the colliery in the pit cage receiving a message from the pit bottom.

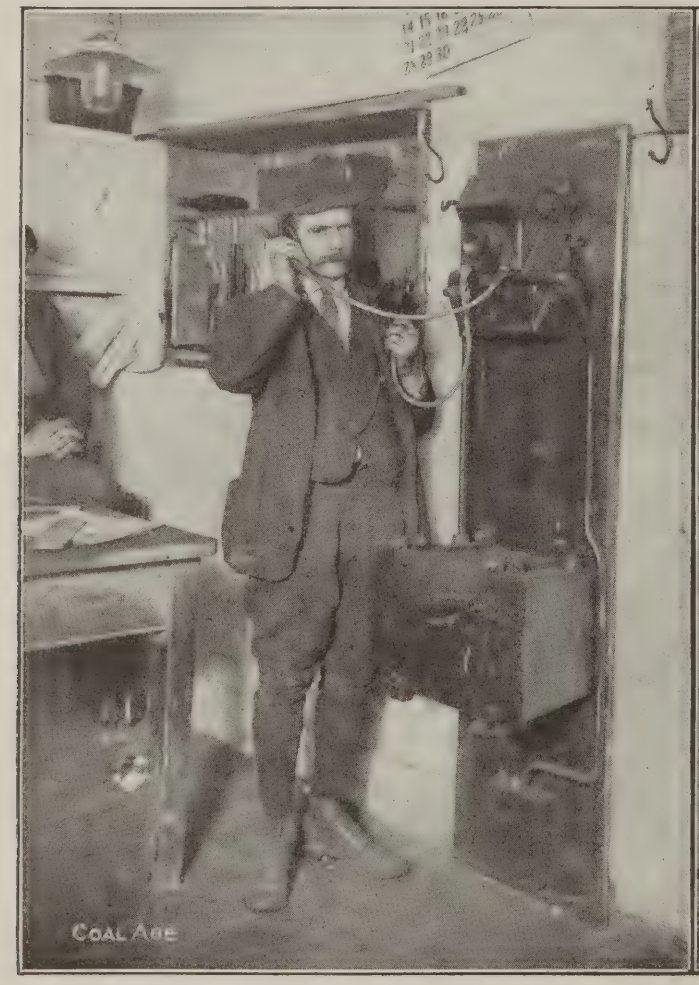


Fig. 1. Colliery Manager at Wireless Phone in Underground Office

Fig. 2. Engineer in Pit Cage Receiving Message from Shaft Bottom .

Rails and Pipes Act as Conductors

In the Reineke telephone, transmission and reception of the speech in the telephone occur exactly as in an ordinary telephone; that is to say, the current strength is varied by the sound waves causing the diaphragm in the transmitter to vibrate, and so vary the resistance offered to the current by the carbon particles in the telephone. This varying current operates the diaphragm of the receiver through the agency of the magnet excited

by the currents. Instead, however, of the current from the transmitter being conducted along wires to the receiver, it is converted to a high pressure by a transformer contained in the telephone case and the high pressure or secondary winding of the transformer is connected to the ordinary rails or pipes in the pit.

In this way, the charge of electricity is communicated in and spreads over the whole system of rails throughout the pit, the charge varying with the fluctuations of the primary current in the transmitter circuit of the telephone. In this system no attempt whatever is made to insulate the rails or pipes or to connect the adjacent lengths electrically. The conditions of distribution of electric charges underground are entirely distinct from the conditions on the surface of the earth and the working of the system largely depends on this fact which was for the first time demonstrated by Herr Reineke.

The reception of speech is accomplished by connecting telephones to the rails or pipes at any point of the system, by bridging a sufficient length to obtain a suitable potential difference, or by connecting between the rails and pipes if these exist, while in some cases it is found convenient, as in portable instruments, to connect to an antenna consisting of a loose coil of wire which may be laid on the floor or hung on the timbers.

A Bell Rings Just as in an Ordinary Telephone

To call attention, a bell similar to that of the ordinary telephone is operated by a specially designed relay. When the button is pressed at the transmitting station, all the bells belonging to the receivers will ring and all the telephones will receive the message by taking the receiver off the hook, which cuts off the bell and connects up in the usual manner.

By tuning the relays, it is possible to make each respond to its own particular signal so as to call any one station, but in mining work this does not appear to be either necessary or desirable, and the different stations are called up by giving one, two or three rings, a special signal calling all the stations to speak simultaneously. The current is given by an ordinary battery, and in outward appearance the telephones are similar to the ordinary mine telephone.

One form of the instrument is exceedingly portable, weighing with its case about 20 lb., enabling it to be carried about and used in any part of the pit to which the rails extend. It can either ring up other stations or be rung up by them. A smaller or pocket instrument can also be made which can ring up other stations, but cannot be called by them, but messages can be exchanged from any of the fixed telephones. This is useful for an overseer, who thus can give notice of any accident and ask for assistance from any point whatever in the pit.

A telephone can be fixed at any position on the surface and connected to the head gear if desired, or to the winding rope or pipes which go down the shaft. This telephone can speak to any of the telephones underground if necessary, but it is usually found convenient to enable it to speak to the station at the pit bottom only and for this station in turn to deal with the underground telephones. In metalliferous mines which have a number of different levels running from one shaft, communication from one level to the other is established without the presence of ore affecting the speech in any way.

Can Speak from a Moving Cage

A special application is the speaking from the moving cage to the winding-engine house. For this purpose the telephone is mounted on a standard which brings it close to the engineman's ear. On receiving a call he has only to put his ear to the receiver, the slightest pressure being sufficient to switch in the telephone and allow him to communicate with the cage without lifting his hands from the levers.

For the telephone in the cage, one of the best methods of connection is the connection into a loop formed by the winding ropes and by the balance rope, or if this is not used, by a wire suspended below the cage in the same way. It is then possible to speak from the cage either to the surface or pit bottom without any alteration to the ordinary winding arrangements. The surface telephone is preferably connected in circuit with a loop of wire, which is fixed to the headstocks or in the shaft in any convenient place.

System Is Absolutely Safe

We are indebted for this information to the Reineke Wireless Telephones, Ltd., and also to a paper before the Institute of Mining Engineers, by T. W. Wallis, at a visit to the Astley Green colliery, Manchester, England. The system appears to provide numerous advantages. It is claimed to be absolutely safe because there is no possibility of producing a spark under any conditions. It provides complete certainty of communication as there are no connecting wires to be interrupted. It can easily be moved from one place to another if required and it cannot be affected by, or affect other electric circuits in its neighborhood, whether these are direct or alternating currents conveying power, or used for signaling. Moreover, it is not interfered with by ordinary wireless telegraphic signals. The system therefore appears to have a great future and opens up quite a new phase in the problem of underground telephony.

Consular Market Notes

The U. S. Consular service makes the following comments on the foreign markets:

Silesia—There was a lively and continuous demand during the year for Silesian coal, especially for industrial purposes, in Germany, Russia and Austria-Hungary. The mining strike in England made German, Danish, Swedish and Russian customers buy from Silesia, and the strike in the Ruhr district in Germany increased the demand. As the river conditions were unusually good, the only complaint heard was of the car shortage, which was worse than ever, especially in this district. This shortage begins every year in the middle of September and ends in November with the close of the sugar-beet harvest.

The production of stone coal in the province for the past three years in metric tons (metric ton = 2204.6 lb.), was 39,993,239 in 1910, 42,300,412 tons in 1911 and 47,445,170 tons in 1912.

Australia—Export statistics of Newcastle for the first nine months of 1913 show gratifying trade increases over the similar period last year. Coal shipments totaled 3,786,432 tons, valued at $9,645,727, increases of 166,756 tons and $490,625, respectively. It is announced that a contract for supplying 100,000 tons to Java has been obtained for Newcastle.

Gibraltar—Coal trade of this port has increased during the last few years, and further development is looked for in 1913. In 1912 the total number of steamers calling for coal was 2010, and 239,051 tons were sold, an increase of 180 steamers and 7916 tons over the previous year. The current price for Welsh coal is $7.17 and North Country $6.32 per ton f.o.b. No American coal has yet reached this market.

Belgium—In 1912, 5,784,850 tons of coal were sold in the Liege consular district. As compared with 1911, the amount of coal sold increased 455,950 tons, or 8.6 per cent. The total increase in value of the coal output was $3,218,305, the increase in price per ton being 36c. for semihard, 28c. for hard, and 19c. for soft coal. The net profits of the coal mines amounted to $1,682,168, or an increase of $751,994 over 1911.

The coal market showed great strength in 1912, especially in coal for industrial use. Coal for household use was not in great demand, on account of the exceptionally mild winter. One result of the firmness of the market was an increase in the price of coal.

An Analysis of the Ohio Mining Commission's Report

By A. T. Shurick

SYNOPSIS—The second and concluding article on the Ohio Mining Commission's report. The arguments of both the miners and operators, for and against the proposed new legislation, are discussed in detail. The main contention of the miners appears to be founded on an intangible psychological condition. The commission finds that the impurities in the finer sizes will be so increased under the screened-coal system that they will be practically worthless unless washed. Although the operators' arguments are sustained by the commission itself, in nearly every instance, the recommendations are made in favor of the miners. The report makes the incongruous blunder of condemning without attempting to prescribe a remedy.

The report next enters into a detailed analysis of the arguments of both parties to the controversy.

The First Objection of the miners is that on the present basis of payment they are "not paid for the whole product of their labor." The commission is of the opinion that while this "will not bear analysis, it is probably true that this assumed grievance is the most serious defect in the present system of wage payment." Obviously it is a psychological effect, a condition of the mind, rather than a real, tangible grievance. Even the old, original report of 1883 pointed out: "The stubbornness of this misconception is hard to overstate." But it is none the less based upon such absurd contentions, that it would hardly seem to justify the consideration of serious men of affairs. For these rather illogical reasons, the commission shows a tendency to agree with the miners in their position.

A more tangible reason for sustaining this objection would seem to lie in the loss of fine coal, as is pointed out in the report. Under the present system of payment the miners do not benefit by loading out the smaller sizes, so that a certain proportion of these must be lost to posterity. But even this loss is so small that it cannot be considered important when compared with the average mining practice throughout the country.

It is generally true, however, as the report ultimately sums up, that since "the miners believe that they are not being paid for a portion of the product of their labors, and that this results in grievances, causes of disputes and bitter feeling between miners and operators," it is obviously desirable to effect an agreement providing it can be conclusively shown that no material injury will result to either party.

Inaccuracies of the Screen-Coal Basis

The Second Objection of the miners is that the percentage of lump coal is fixed in a more or less arbitrary manner. If, as the commission states, the amount of screenings made at the different mines varies between such extremes as 5 to 45 per cent., this certainly is one of the "strongest arguments against the present system." Not only do the operators generally benefit over the miners, but companies in different districts have a certain economic advantage over those in others. The commission is uncertain as to how much weight should be given to this objection, becauses, "under any system of collective bargaining, inequalities are bound to exist," but surely there is little excuse for a discrepancy of such proportions as this. It is not by any means an unusual practice to fix the wage scale according to the varying conditions in the different districts, and it seems that a satisfactory solution to this difficulty might be effected in this manner.

The Third Objection of the miners to the screen-coal basis of payment is that: "It is to the interest of the operators at some mines to produce a large amount of fine coal," and a number of methods of roughly handling the coal in order to obtain this end are cited. It is true that a mine may occasionally (though very rarely) find it necessary to crush a portion of its output in order to meet a temporary heavy demand for slack coal. On the other hand, this might have been readily purchased in the open market, and the differential in value between the two saved. Indeed conditions where the operator could profit by increasing his proportion of slack, so seldom occur in the commercial end of the industry that to all practical purposes this contention of the miners can be ignored.

Discrepancies in the Proportion of Screenings

The Fourth Objection of the miners charges either deliberate negligence or a studied unfairness on the part of the operators in screening the coal. It is claimed that while the companies usually comply with that part of the agreement providing for screen bars spaced 1¼ in. apart, these wear away rapidly, permitting a greater amount of coal to pass through than should. If the findings of the commission are to be given full credence, the operators have been excedingly lax in this respect and should be taken sharply to task. The commission states that it took measurements of the screens at all the mines visited and that it was *seldom* that one was found fulfilling the prescribed conditions.

Of course, there are extenuating circumstances in this connection, since it might be said that after the first day's use the screens may be sufficiently worn to make an infinitesimal discrepancy. Obviously the operators should not be required to replace such a screen, and in fact it becomes a question as to just what variations from the 1¼-in. spacing should be permissible. It is clearly a strain upon the integrity of any operator to require him to purchase new screen bars when such expenditure works to his disadvantage. It is, therefore, not to be wondered that the miners have experienced exasperating delays in prevailing upon the companies to replace worn screens.

But when the commission refers to this as "a system which knows no remedy but a strike," one feels obliged to immediately take issue with such a statement. Certainly some practical method might be evolved for solving this difficulty as, for instance, the operators could be required to make the original spacing of their bars 1⅛ in., and to replace them when the opening exceeds 1⅜ inches.

Different Coals Produce Varying Percentages of Slack

The Fifth Objection of the miners is, that owing to the varying hardness or softness of the coal in different mines, and even in different parts of the same mine, a corresponding higher or lower percentage of lump coal is obtained. Naturally a great variation of this kind would affect the earnings of a miner appreciably, although the commission is of the opinion that it is not a weighty consideration. In any event it is a difficult matter to ascertain, and could only be arrived at by careful experimentation with each mine and even different parts of the same mine. Generally speaking, it might be said that differentials in the working places at all mines is an ineradicable evil. Even under the present mine-run system all know that each mine has its "good" and its "bad" places, it being the customary practice to bestow the more favorable upon the best workers or the oldest employees.

Sixth Objection.—Coming finally to the concluding argument of the miners we find this to be founded on the contention that since the operators benefit by obtaining a large proportion of slack there is no premium placed upon skilled labor. As the report rightly points out, the validity of this claim hinges on the commercial value of the finer grades. In the opinion of the commission the large proportion of unskilled labor in the mines today is due to the introduction of mechanical devices, which has eliminated the necessity for trained labor. It might further have been mentioned, in this connection, that there is usually a great scarcity of labor and that it is becoming increasingly difficult to attract any but the lower class of workmen to the mines.

The Operator's Objection to the Mine-Run System

The crux of the argument is finally arrived at in "the operators' objections to the mine-run system," and a more or less successful effort is made to prove the uneconomic principles upon which the miners' demands have been conceived.

First Argument—As an opening gun on the subject the operators endeavor to undermine the fundamental principles upon which the miners' demands are based, by seeking to have the claim for legislative interference set aside. Accordingly they point out the fact that the miners' organization is one of the most powerful in the country and well able to adequately protect its own interests. Labor has indeed learned its lesson from syndicated capital with its interlocking directorates, alliances, etc., and has, in fact, become syndicated labor, with a latent brute power of passivity no longer to be denied.

The producers also show that legislative action in this connection materially weakens their position in future wage contentions with the miners. This position of the operators is well taken. As all know, the periodical fixing of wage scales invariably winds up in a compromise, each side giving and taking until an agreement is finally reached. This ruthless seizure of what might properly be considered one of the most valuable assets of the operators is clearly unjust. Or, as the operators point out, if this condition must be met it is only logical that a fair and equitable wage scale should be fixed upon under the same arrangements. They have also shown a commendable fairmindedness in this connection by repeatedly offering the miners the same wage scale as now in effect in Illinois and the fact that the latter have consistently evaded a definite reply to this condition, must inevitably lay them open to suspicion.

Although the commission concedes that to take away from the Ohio operators the right to grant the mine-run basis of payment will seriously handicap them at the pending wage conference, it nevertheless feels that it "cannot push this objection very far." This it does on the premises that its instructions were to find an equitable basis of payment if the present mode should be considered unfair. Apparently the commission assumes its instructions to take precedent over all considerations of an economic character—an obviously unsound principle.

An Increased Percentage of Fine Coal

Second Argument—This objection of the operators is based upon the contention that the adoption of a mine-run system of payment must inevitably bring about a large increase in the production of slack coal. The controversy focuses on this phase of the problem and the powerful arguments which the operators advanced, are ample evidence of the almost panicky fear in which they hold the adoption of any such measure.

It is, of course, clear, as the operators point out, that heavy shooting of the coal would, no doubt, be a result of the mine-run system of payment, since the miner would have nothing to lose by an excessive breaking up of the coal, whereas his labor would be materially lessened. If, as the operators claim, a great deal of trouble is already experienced in finding a profitable market for finer grades, an increase in the proportion of these must naturally be viewed with apprehension.

The commission clinches this argument by citing the testimony of a coal inspector, with broad experience, whose company uses three-quarters of a million tons of Ohio coal annually. This witness states that at the second screening of the Ohio coal, at the head of the Lakes, from 35 to 40 per cent. of slack is taken out. In answer to a direct question as to what effect a further increase of slack would have, he stated that "it would certainly work to the disadvantage of Ohio coal and would have a tendency to cause us to seek coal elsewhere," and, further, in reply to a question along similar lines: "From my standpoint as an inspector, I would certainly advise our people to dispense with the use of that coal."

This issue is more or less generally conceded by all parties to the controversy, and as the commission directly points out, the situation hinges upon just what the increase in the percentage of slack would be under a mine-run system of working. While confessing its inability to reach a decision on this matter, the commission states that all are agreed that where shooting off the solid is practised, the increase in the percentage of slack would be large. But since only between 5 and 10 per cent. of Ohio coal is mined in this manner, this does not become an important consideration. The operators rightly contend that the miner is compelled to use precaution in shooting his coal under the present system and even goes to extra labor in breaking up large lumps, while under a mine-run basis of payment he would be relieved from any restraint whatever in this connection, with the result that indiscriminate blasting of the coal would be practised which must inevitably result in a large increase in the production of slack.

Harry N. Taylor on the Slack Question

The arguments of the operators certainly lack nothing in plausibility, but the commission finds that the miners advance equally sound arguments in rebuttal. They claim that such heavy shooting as described by the operators would blow down the props and scatter the coal so that it could not be recovered. It is clearly a delicate question to decide and one that may vary greatly in different mines, kinds of coal and even with the personal equation of the miner himself. Because of the contradictory nature of the testimony, the commission freely conceded that it has been unable to arrive at a definite conclusion on this subject and that it has been obliged to rely upon testimony of witnesses residing outside of the state.

For this reason, then, it has rested its case almost entirely upon the opinion expressed before it by Harry M. (N. ?) Taylor. Mr. Taylor states that "in the solid-shooting mines there is an enormous increase in the percentage of screenings and the quality of the coal has been deteriorated by the mine-run system, but where the coal is undercut by machines this condition does not exist." In view of the great importance attached to this testimony, one is rather inclined to investigate the record of the witness in order to determine his credibility. In reviewing the history of Mr. Taylor*, it is noted that he has had an almost spectacularly successful career. He has advanced rapidly and apparently upon his own initiative from one position of responsibility to another and has been repeatedly honored by appointment to the highest office which it was in the power of his coworkers to bestow upon him. He is a man of unblemished character, vigorous personality, quick and accurate decision and occupies a preeminent position in the coal industry.

Credibility of Taylor as a Witness

But some question may arise as to the competency of Mr. Taylor's testimony on conditions in Ohio, when it is noted that his experience in that field was confined to a period of six years, between the ages of 16 and 22 years, and that he left there 27 years ago. It would seem that testimony based upon the impressions formed by a mere stripling over a quarter of a century ago should be carefully balanced before being so freely accepted as the commission apparently does.

But Mr. Taylor's testimony, in the opinion of the commission, adequately refutes the contention of the operators, regarding their fear of an excessive increase in the proportion of slack coal, and the commission believes that the chief danger will be due to the probable increase in the percentage of impurities. The commission states that in their opinion the operators should be protected to the extent that they should not be required to pay as much for the smaller grades as the larger sizes.

But when it says, "the contracts between operators and miners to have the men paid on a mine-run basis might be made conditional upon keeping the amount of fine coal within the limits established by this fixed percentage," one rather gathers the impression that the commission retains the privilege of readjusting its conclusions to suit its convenience. On pages 37 and 38 of the report, the commission points out the large discrepancies in the amount of screenings made, finding on occasions variations ranging from 5 to 45 per cent. In the minds of the commission, this was considered "the strongest argument against the present system." If such difficulties arise where exact methods have been specified for accurately determining the amount of slack made, what might the discrepancy be when less effective measures are used?

Before finally closing the discussion on this subject, the commission comments on the broader general usage into which these finer grades are coming, and their consequent enhanced value. The report states that the demand for these grades is increasing to such an extent that it is occasionally necessary to even crush the larger sizes. While it is true that appliances have been devised for burning fine coal, and there has been considerable development in this direction in the past decade, it is equally true that special and rather elaborate equipment is necessary, and that where the consumers go to this extra expense they must naturally expect to profit in their fuel bills. Indeed it would appear that the general assumption that an important market for the finer grades has already developed, would show a tendency to anticipate industrial advancement that is yet to be realized in actual practice.

Increased Impurities under the Mine-Run System

Third Objection—The third objection of the operators is that the mine-run system would result in a great increase in the amount of impurities which, in the words of the commission, "is the strongest objection to the adoption of the mine-run system." The report enters into a detailed discussion on the technique of cleaning coal underground and the difficulties attendant upon obtaining satisfactory results. The necessity for a thorough cleaning of the coal is also dwelt upon at some length. Strenuous competition with coal from other states compels the local producers to insist upon as thorough cleaning as practicable, and even where considerable expense is gone to in this direction, it is shown that consumers still continue to complain.

The report then takes up a number of methods of treating coal to remove the impurities, laying considerable emphasis upon the washing process. The fact is brought out that mines operated on the mine-run system in Illinois are generally equipped with washers as well as other devices for thoroughly sizing the coal. It is also shown that the few washers which have been installed in Ohio have not "proved very successful from a commercial standpoint," in spite of which fact, however, "the commission feels compelled to say that Ohio operators might well go farther to get clean coal." This rather ambiguous conclusion is difficult to reconcile.

On the other side of the question, however, the miners claim that they would clean their coal as well under a mine-run basis of payment as under a screen-coal arrangement. It is stated that these arguments "did not greatly impress the former commission" before whom they were also placed and "neither do they greatly impress the members of this commission." It is generally agreed by all that most of the miners make an honest endeavor and go to a reasonable amount of trouble on their own initiative to load clean coal; but since only a small percentage loading poor coal may have a serious, if not disastrous, effect upon the average product of the mine, the promulgation of any recommendation affording opportunities for increasing the impurities should be given serious consideration.

*See "Coal Age," Vol. 2, page 292.

The commission agrees that if the mine-run system opened fresh opportunities for the miner to load impurities that some at least would do so, and "would not other men employed in the mine be tempted to do the same thing?" It is conceded that such a temptation would exist, and "that even 10 per cent. of dirty loaders at a mine would make it difficult for operators to get their coal in marketable shape." But the operators must be rather startled at this point to note that the commission states: "miners say that they do not demand pay for dirt." In view of the fact that it is customary to "dock" or fine miners found guilty of loading impurities, it is gratifying to note that the men are at least prepared to temper their demands to the extent of not demanding pay for loading such impurities. Indeed the commission quite appropriately asks: "How is it possible to clean the coal before it is weighed?" Obviously this is impossible.

Testimony on Impurities Question

Testimony was taken from both operators and miners as to what effects the adoption of the mine-run system would have upon the percentage of impurities in the coal, and as was to be expected the evidence was of an exceedingly contradictory nature. The miners testified to a man that equally clean coal would be produced under the mine-run basis of payment, as is now obtained with the screen coal. The operators are equally positive that there would be a large difference and cite the effects of the mine-run system according to the report of the state geologist of Arkansas, while the commission itself agrees that the testimony of operators in other states tended to substantiate this belief.

In attempting a solution of this intricate problem the commission again relies almost exclusively upon the opinions of Harry N. Taylor, and in doing so it calls attention to the fact that since the testimony of this gentleman was adverse to the operating interests in the first instance that it is only fair that the miners should accept his conclusions in the present case. As already pointed out, there were grave reasons for taking exception to Mr. Taylor's previous testimony, although the general competency of the witness was agreed to. This exception does not apply in the present instance for the reason that Mr. Taylor has been in intimate touch with the conditions of which he speaks throughout his career.

In response to a query as to what difference exists where a miner is loading coal on a screen-coal basis as compared with a mine-run basis, Mr. Taylor said: "If a man was cleaning up his place, he cleaned it up just as clean as this floor, because he gets paid for it, if it is being weighed and paid for as mine-run." As to cleaning coal, when loading mine-run, Mr. Taylor said: "They don't clean the coal any better; in fact, they shovel in the refuse of the room; that is, they load everything out that weighs anything."

Washers a Necessary Adjunct of the Mine-Run System

Mr. Taylor states further that where the mine-run system has been adopted in northern Illinois, the proportion of impurities in the screenings amounts to between 20 and 30 per cent.—obviously an unmarketable product. This has made it necessary to construct washers in order to remove these impurities and it was shown that this added from 10 to 20c. per ton to the cost of the washed coal.

Mr. Taylor also gives some particularly valuable testimony regarding the impurities in coal, and the various subterfuges which the miners resort to in loading these out. He segregates the impurities into two general classes, the bone coal, which customarily occurs in a relatively thin stratum, "frozen" in an otherwise perfectly clean seam, and the clay minings found in the bug dust.

Speaking of the bone coal, Mr. Taylor said that he has known of repeated instances where miners would take the grease from a car wheel and cover up all evidence of this impurity in a large lump, rather than take the trouble of breaking same up and removing the impurities. As to the bug dust in the coal, Mr. Taylor calls attention to the fact that the addition of this not only forces the operator to pay for something he cannot sell, but that it materially effects the value of his product. In fact where this occurs the finer sizes cannot be sold except by giving them a thorough cleaning in the washer, a condition that was conclusively proved in Illinois, when the mine-run basis of payment became operative there. Mr. Taylor says, finally, that, "the entire method of handling coal in Illinois has been changed."

The question was put up to Mr. Taylor as to whether the miner would load out the fine clay made in working the machine in a clay seam, to which he replied: "The men will load everything that is loose in that room, where under the lump-coal system they formerly left that in because it didn't do them any good," and he went on to state further that it was impossible to apprehend those guilty of doing this.

The commission concludes this phase of the discussion with the statement "that the adoption of the mine-run system would cause a considerable increase in impurities unless some way was found to protect the operators." In view of the subsequent recommendations of the commission that the mine-run system be adopted, it would seem only reasonable that the commission should be called upon to first offer a solution of these obstacles, which even it concedes.

Fourth Objection—The concluding argument of the operators is that they would be forced to "considerable expense in rebuilding and rearranging their tipples." This objection, as is pointed out, is more or less incidental, and there is no doubt but that the operators as a whole would be willing to meet this expenditure under favorable conditions. It would seem, however, that the commission is inclined to under-rate this item, and it will doubtless be found that the statement, "All that would be necessary to do would be to cover the screens and to continue to dump the coal," will not apply to a great many mines. Should the operators be compelled to install washing plants in order to clean their finer sizes, this heavy expenditure will assuredly close up all the small operations in the state and possibly many of the larger.

"Conclusions and Recommendations"

First—The commission finds that the "present mode of payment is not an equitable one," justifying its position in this matter mainly on the grounds of the inaccuracies in screening the coal. As already pointed out, a simple remedy for this evil might easily be devised. In fact, indications point to the conclusion that the commission has recommended according to "instructions" rather than on the true merits of the controversy.

The report also comments upon the inborn prejudice of the miners against the present system of payment, which even the commission itself confesses its inability to substantiate with tangible facts. The commission asserts: "There would be carload after carload of fine coal sold, which has been produced by their labor, and for which they imagine they have received no pay whatever." One feels inclined to ask if the commission has given equal consideration to the feelings of the operator who will probably see "carload after carload of fine coal" going onto the rock dump after the new measure has been enacted?

Second—The second conclusion of the commission refers to the question of the increased amount of screenings and the greater amount of impurities in same. As already noted, the commission agrees that a very material increase in the amount of impurities in the finer grades will result, but it fails utterly to suggest a remedy for this evil.

As to the question of an increase in the percentage of screenings, the commission does not believe this will be of sufficient proportion to be of economic importance except in solid-shooting mines, and since it embodies a recommendation that all solid shooting be prohibited for the reason that this is a prolific cause of accidents, this objection of the operators seems to be adequately disposed of from their point of view. But it should be remembered that this question is still open as the commission failed to prove it as conclusively as some will expect.

Under the proposed mine-run basis the report points out that there would be an incentive for the miner to load out all the fine coal, and that this condition would, therefore, prove advantageous from a conservation standpoint. The correctness of this theory is in much question. The report has quite conclusively proved that the finer grades will carry such a high percentage of impurities under the mine-run system, that it will be impossible to market them unless they are first washed. It may be safely assumed that none of the smaller operators are financially able to undertake the installation of washer plants while it is also reasonable to believe that many of the larger operators will not feel inclined to materially increase their mining investments in Ohio. This brings one to the inevitable conclusion that instead of conserving the coal, as this measure is intended to, it is highly probable that a greater percentage will be lost and the interests of conservation even more effectively defeated than is now the case.

The commission concludes its report by conceding that it is unable to state whether the adoption of the mine-run system will result in the miners shooting their coal harder and states that "it would be the part of wisdom to provide safeguards for the mine owners."

In Conclusion

It would be well for the Ohio operators to prepare for a defeat in this measure. The trend of public opinion is too unmistakably adverse to capitalistic interests to anticipate a decision favorable to them. The best that can be expected is the customary compromise which, however small, spells victory to the miners since they have nothing to lose and everything to gain.

Whether one be for or against the political innovations of the present day, all must agree as to their radical nature. Driven on by an insistent popular clamor, the movement is evident on every hand from the insignificant city council to the national assembly at Washington. Time alone will prove the wisdom of these new departures, but it is a significant fact that serious physical conditions are already arising that throw grave doubts over the future. The attacks on corporate interests are by no means at an end and we are even now facing the problem of restoring the confidence so essential to the aggressive expansion which has characterized American enterprise in the past.

Class legislation is becoming so common that it is no longer thought necessary to attempt concealment. A notable example of this is the "rider" attached to the Sundry Civil bill enacted last year, providing that no part of the $300,000 fund set aside for prosecutions under the Sherman act should be used in cases against labor unions or farmers. A direct law exempting labor and the farmers from action under the Sherman act would have been promtly declared unconstitutional.

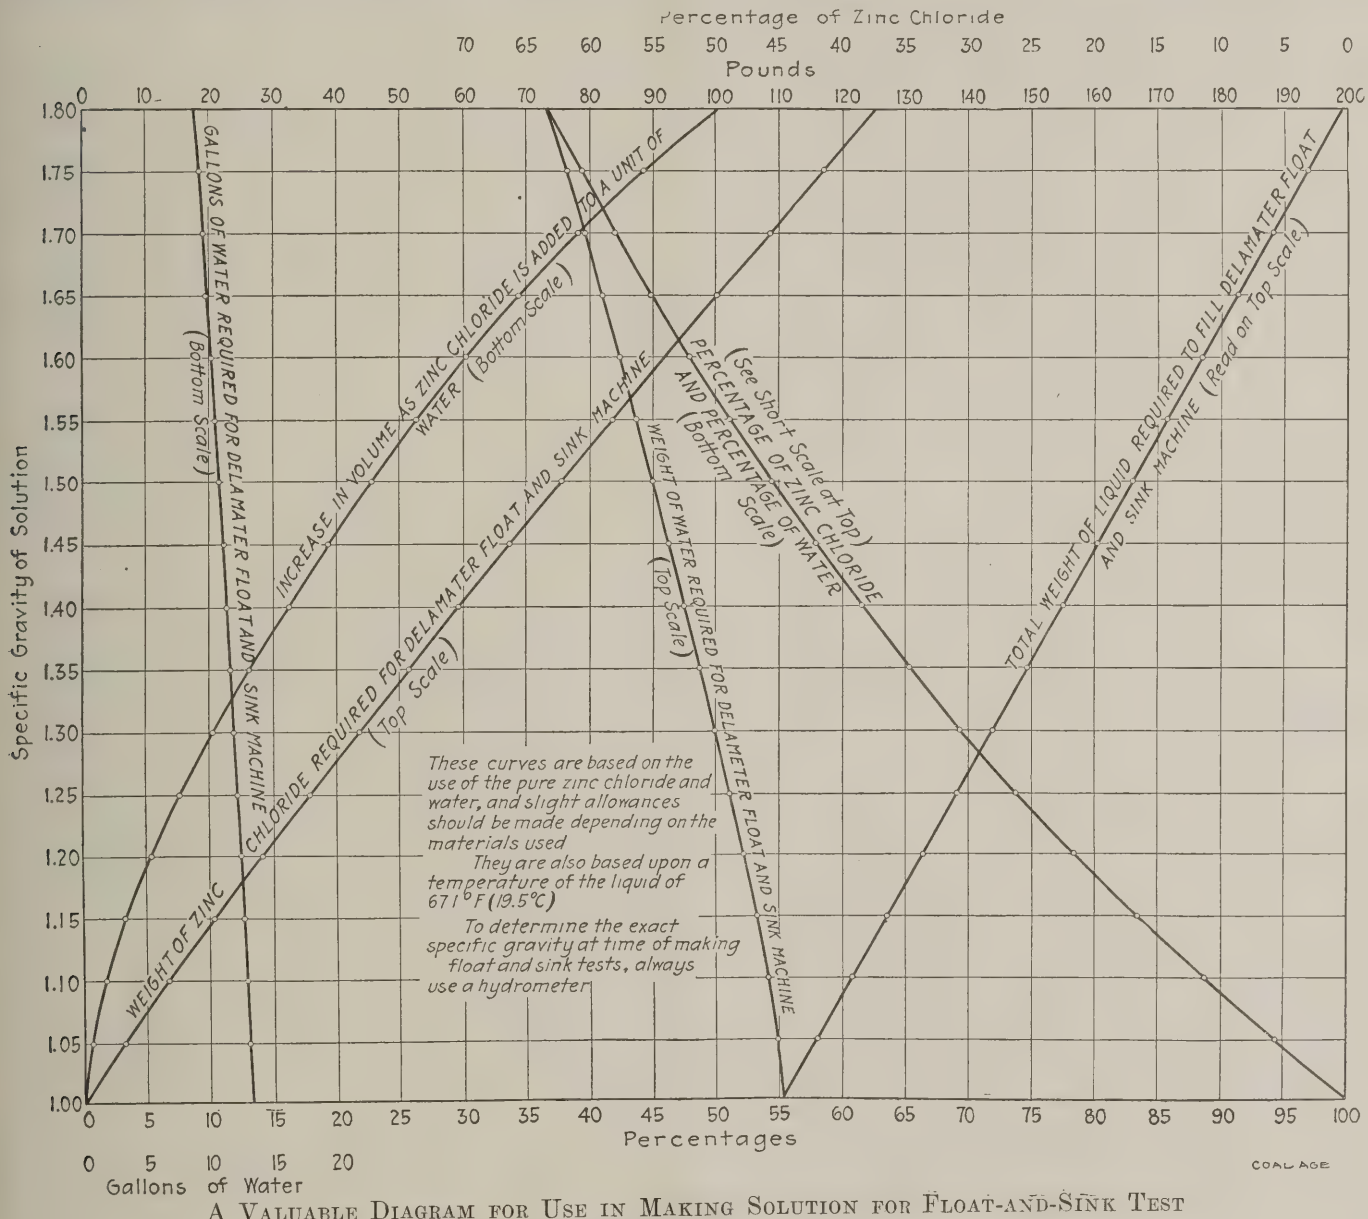
A Transitional Period

Our best students of economics are agreed that a transitional period is at hand. The representative form of government was an institution developed by oppressive political conditions that have long ceased to exist and it has not been found effective in dealing with the intricate problems relating to competition, insurance and credit. In fact it is the consensus of opinion among the best thinkers of the day that our entire social system is strikingly unfair.

The trouble is largely a psychological one, a protest against fundamental conditions, rather than the mere question of hours and wages. The proletariat is becoming more sensitive and critical with the wider diffusion of education while the modern changes in the character of labor are tending toward a loss of individuality and hence creating a lack of interest and a subsequent dissatisfaction. The evils of the fiduciary system, wherein the owner is replaced by a manager or agent, is also a prolific cause for disturbance.

As to remedies for these new conditions one finds a great diversity of opinion. Some think there must be a radical readjustment in the conditions of labor, with provisions for old-age pensions, etc. The socialists, of course, demand their "disciplined democracy" and make a strong plea for a closer understanding and more intimate relationship between the laborer and his employer.

But whatever the corrective, the conservative thinker will agree that it must be one of gradual evolution. Society is too complex, too strongly established to make feasible an abrupt and arbitrary revolution without precipitating an untenable economic situation. Radical innovations tending to effect abrupt changes in established lines of industrial endeavor are to be viewed with suspicion. The world's commerce is gaged upon delicately balanced fundamental conditions, the ruthless disruption of which must inevitably be accompanied by dire results.



Postscript—Since the publication of the first article on this subject, later advices from Ohio have been received which indicate an even more tense situation there than was thought. While we are not at liberty to use the additional information at the moment, it is probable that Coal Age will have some interesting disclosures to make in this connection in the near future.

A Float-and-Sink Test Diagram

In the washing of coal, it is often desirable or absolutely necessary to determine whether or not the washer is doing the work expected, or whether the separation of the coal from the slate and other impurities is as complete as required. Attention was drawn to this matter in an article by G. R. Delamater entitled Washery Plant Control, COAL AGE, July 20, 1912, p. 82. In that article, Mr. Delamater described what is known as the "float-and-sink test."

The test consists in preparing a solution of zinc chloride of such density that the purer quality of the washed coal will float therein, while other portions of the coal that contain too much impurity will sink to the bottom of the tank. In making this test, the float is skimmed from the surface of the liquid, dried and examined. In the same manner, the sediment at the bottom of the tank is removed, later, dried and examined. Without going further into the details of the test, which was fully described in the article mentioned, the accompanying diagram is sufficiently self-explanatory to be of interest.

The vertical scale at the left shows the specific gravity of the solution, while the curved lines of the diagram show, respectively, the gallons of water required in the use of the Delamater machine; the weight of zinc chloride, weight of water and total weight of liquid solution, corresponding to any given specific gravity from 1 to 1.8, which is a sufficient range for any ordinary coal test. The diagram also shows the corresponding percentage of zinc chloride and percentage of water, together with the percentage of increase in volume caused by the addition of the salt to the water.

A VALUABLE DIAGRAM FOR USE IN MAKING SOLUTION FOR FLOAT-AND-SINK TEST

While the diagram is an ingenious combination of curves giving the data that are of particular interest in testing the results obtained in the washing of coal, it is recommended that use should always be made of a suitable hydrometer to check the specific gravity of the solution when making a test; as the temperature and any differences in the materials employed will vary the density of the solution to a slight degree. The diagram is particularly useful in making up solutions for a given test.

The Gases in Coal

N. H. Darton, geologist in the U. S. Geological Survey, addressed the New York Section of the American Institute of Mining Engineers on Friday, Jan. 16, in the Engineering Societies' Building, 29 West Thirty-ninth St., New York. The address entitled, "Mine Gases" covered some researches and inquiries into the problem of gas emanation conducted under the auspices of the U. S. Bureau of Mines, with which Mr. Darton was for some time connected. Mr. Darton, while perhaps not a forcible speaker, has a remarkable facility of expression and a clear comprehension of his subject.

Stratigraphy and Gas Emission

The Bureau of Mines experts made their experiments in southern Illinois and in the northern anthracite field, the object being largely to connect if possible the stratigraphic conditions—cover, flexure, depth and faulting—with the volume of gas emanation.

It seems to have been in a degree a blind lead for on the whole the methane content and the emission of the gas, according to Mr. Darton, depend rather more on the actual coal substance than upon the conditions of occurrence mentioned. Yet as will be seen there are exceptions which will be later stated. The origin of the coal, its proximate composition and porosity, none of which were investigated, Mr. Darton declares, are the determinants of its gas-giving qualities. These facts are, of course, shrouded in much mystery and there seems no way of assuring oneself as to the volume and character of gas given off by any seam or part of a seam except by actual test. However, Mr. Darton's facts as collected are of great value and no little interest.

Volume of Gas in Coal Samples

The volume of gas given out by coal subject to laboratory examinations varies over a wide range. English bituminous coal gives a volume of gas 75 to 82 per cent. of its own volume; cannel coal from the same country 40 to 70 per cent.; semibituminous 99 per cent., steam coal 500 to 811 per cent. and the Ryhope coal 1000 per cent. The coal at Nanticoke, Penn., gives a volume of gas 3.1 times its own volume (310 per cent.) that at Benton, Ill., after 75 weeks 1.82 times, that at Harrisburg, Ill., after 40 weeks 1.05 times, that at Pocahontas, Va., 0.047 times in 45 weeks and that at Connellsville 0.16 times in 60 weeks. It will be seen that anthracite contains the most gas.

The Impermeability of Coal

An attempt was made at the Bellevue mine in Belgium to show to what extent the gas was bled by workings advancing toward coal and it was shown that coal is extremely resistant to the transpiration of gas through its pores. At Beaulieusart mine in Belgium it was proved that violent outbursts breaking down large quantities of coal lowered pressures in the coal bed and might at a near-by point prevent them from reaching their former values and even deter them from exhibiting any subsequent recovery. But at a point only slightly remote, the drop following an outburst was only temporary and the pressure continued to rise after the decline in pressure was compensated. The difficulty in bleeding gas from coal was most forcibly illustrated by these experiments.

Gas Pressures in English Coal Rise to 425 Lb.

L. Wood gives the following pressures of gas obtained in English coal mines. A hole was drilled in the coal, a pipe was inserted and the space between the pipe and the sides of the hole tightly tamped, the pressure developed being measured by a gage.

GAS PRESSURES IN ENGLISH COAL MINES

Mine	Depth of Hole, in Ft.	Pressure in Lb. per Sq.In.	Time Pressure Takes to Reach Maximum in Hr.
Bolden	19	425	190
	23½	381	25
	28	176	60
	32	461	60
Eppleton	3½	54	1
	7½	104½	34
	24½	204	106
	25	221	51
	37	223	174
	47	235	294
Harton	16	197	135
	27½	231	126
	37¼	296	84

Some attempt has been made to represent by a formula the relation of pressure to depth from coal face but the exceptions are almost as important as the agreements with the formula propounded.

Gas and Depth of Cover Have Little Relation

Apparently Mr. Darton's experiments showed that gas does not collect on anticlines unless they contain a large amount of crushed material. Sandstone in an arch will break and leave crevices, and gas may be found under such conditions but when the roof is shale which will flow readily, the breaches of folding are soon healed and the roof becomes so unbroken and impervious that gas cannot collect. So drillers may look for natural gas in anticlines but mine gas is not usually to be found in any greater quantity there than in synclines.

It was thought that deep coal would perhaps be excessively gassy because the opportunity for the release of gas is not provided where beds are protected by heavy cover, but while the gas content increases with depth up to 200 ft., greater depths do not seem to make any change in gaseous emanations. It was thought that the coals south of Nanticoke which are 2500 ft. below sea level might be rendered unworkable from this cause but the facts established hardly favor this idea.

Yet the nature of the cover is believed to have some effect. A chalk cap in Europe is supposed to have caused an increase in methane content and an igneous rock formation in Natal is also credited with making coal gassy.

Relation of Gas Emitted to Area Exposed

Most of the measurements made were to discover the relation of the volume of gas emitted to the coal area exposed in districts of mines making gas. And this was found to vary not only from seam to seam but freakishly in the same seam. Of course, this variation is somewhat generally known and it seems to have some connection with the paleobotany of the formation and the porosity of the coal. In the Lance Colliery, Penn., the emitted gas was as follows:

GAS IN LANCE COLLIERIES

Bed		Cu.Ft. per 1000 Sq.Ft. of Coal Exposed
Red ash		0.73
Ross		1.00
Five foot	—East Side	1.67
	—West Side	0.23
Hillman	—East Side	2.30
	—West Side	1.00

The gas in the South Wilkes-Barre colliery ran 0.22 to 5 cu.ft. per 1000 sq.ft. The Dorrance mine near Wilkes-Barre is probably the most gaseous shaft in the world. It produces 3390 cu.ft. of gas per min. The Red Ash at that colliery emits 1 cu.ft. per 1000 sq.ft., the Five-foot 2.5 cu.ft. and the Hillman 1.8 cu.ft.

Effect of Idleness on Gas Emission

A strike occurred during the course of the investigations and an opportunity was afforded to gage the effect of the idleness of the workings on the emission of gas. The results were contradictory but they did establish the fact that working or idle the mines appear to be about equally gaseous and sometimes emit even more gas after the stoppage than before. Thus for the Lance mine the following figures were obtained:

GAS FROM LANCE MINE OPERATING AND IDLE

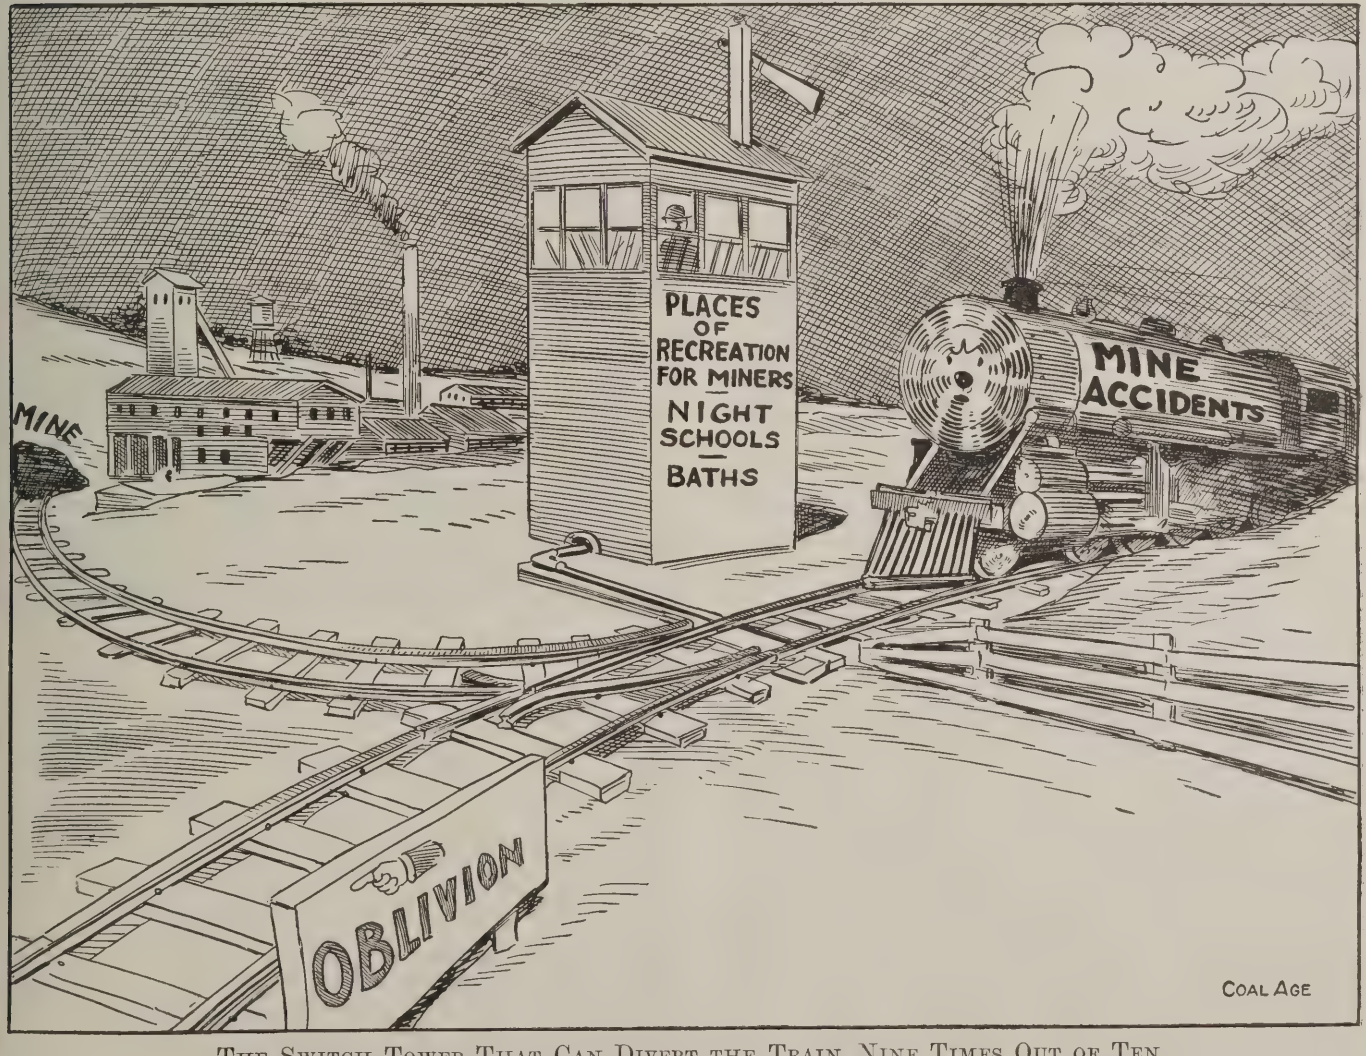
Current	Volume Under Working Conditions	After a 2-week Strike
Total upcast	2690	3120
Hillman	555	706
Cooper	508	678

But some other anthracite mines show a decrease and in Illinois there was usually a decline in emission as a result of the suspension but not always.

The pressures in the Illinois mines were quite variant. The mines showing the highest pressures of those measured were Ziegler mine 25 to 33 lb. per sq.in. and Dering No. 18 24½ to 24¾ lb. The United mine, strange to say, showed no pressure whatever.

The gas may be estimated in cubic feet per ton mined and the table below shows this relation.

GAS LIBERATED IN TERMS OF TONS MINED



Locality	Cu.Ft. per Ton Mined	Relative Volume of Gas to Coal
Germany	16 to 1060	½ to 30
Austria	7469	300
Wilkes Barre	1500	60
Anzin, France	1377	55

[These figures are much larger than those of laboratory tests, which, perhaps, is natural.—Ed.]

Mr. Darton said that though a low barometer caused an increase in gas escaping into the airways it did not cause sufficient to endanger a well ventilated mine.

Gas and Seisms

The discussion largely turned on the effect of earthquakes in causing explosions, and of volcanic release in making them less likely. When an earthquake takes place, the gas in the measures is possibly liberated by the shaking. If care is not taken this gas is ignited and explosions result. No one asserted that the alleged coincidences in the occurrence of earthquakes and explosions proved that a connection existed between them and as someone pointed out many explosions probably resulted from dry coal dust only and such disasters could not be charged to seismic action.

The Switch Tower That Can Divert the Train Nine Times Out of Ten

Who's Who--In Coal Mining

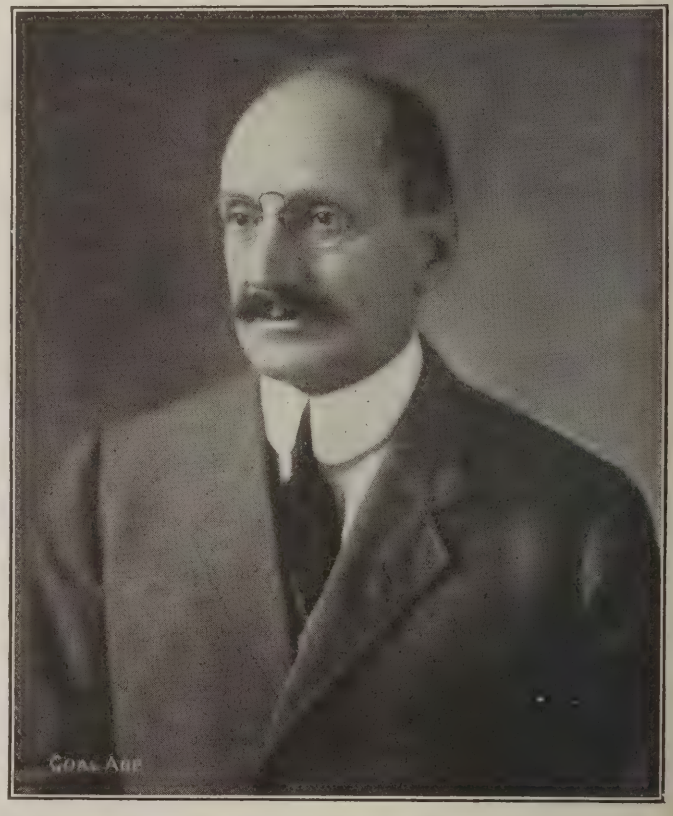
After Director Joseph A. Holmes, the one man who has been most closely identified with the inception and development of the United States Bureau of Mines, is Herbert M. Wilson, the engineer in charge of the experiment station of that bureau in Pittsburgh, Pennsylvania.

Though educated in mining, as well as civil engineering, Mr. Wilson, whose practice has been largely along other engineering lines, owes his active association with the mining industry to his capacity in managing engineering work.

When in early 1907 Secretary James A. Garfield added a technologic branch to the United States Geological Survey, Director Charles D. Walcott, of the latter institution, selected Doctor Holmes as the chief of the new division, and as his principal assistant, H. M. Wilson was appointed because of his proven capacity in the organization and management of some of the most important of the engineering works of the Geological Survey. Mr. Wilson entered upon his duties as chief engineer when the technologic branch consisted only of divisions of fuel-testing and structural materials testing and investigations.

In the next two years the foundation was laid and the work fully organized for the testing of the fuels of the United States, much as it is now conducted in the Bureau of Mines, and testing and investigations of the structural materials for the United States as now carried on in the Bureau of Standards were also developed to practically their present status.

At this time also began the investigation of mine accidents. The result of this work was such as to attract the attention of the nation and of Congress to the need of a Bureau of Mines to carry on such work, and this was authorized by Congress in 1910. The headquarters for the field and technical work of that bureau were established in Pittsburgh, where Mr. Wilson has since been stationed as an engineer in administrative charge.



During the formative work of the Bureau of Mines, the subject of this sketch had opportunity to familiarize himself in detail with the various lines of work conducted by that bureau, serving successively as active technical head of the fuel and mechanical investigations, and of the chemical and physical investigations pending their organization into divisions under separate chiefs.

In the beginning of the mine-accident investigations Mr. Wilson was closely associated with the design and installation of the equipment for testing of explosives, and the building of the various rescue cars and stations, and with other branches of that portion of the mining work of the bureau associated with safety work. In addition to all this, he still continues the active direction of the field force concerned in safety demonstrations and training, and the management of the rescue cars and stations, and their personnel.

The humanitarian side and the educational methods of that portion of the work of the bureau necessary to the extension of safety, education and training could not have fallen into more sympathetic hands. Herbert Wilson's active interest in the welfare of the workman and his well-being was promptly recognized and he was soon drafted as one of the organizers and as a member of the executive committee of the National Council for Industrial Safety. He has been actively identified with the work of the National Fire Protection Association in its efforts to bring about safety from fires in cities and in mines, being chairman of the Committee on Mine Fires.

Helped to Create the American Mine-Safety Association

He was actively identified with the organization of and was first president, and is now secretary, of the American Mine-Safety Association. This was the first step toward

Herbert M. Wilson

bringing together the operators and mining engineers for the standardization of safety apparatus and first-aid-to-the-injured methods. With a zeal born of the inspiration of a great humanitarian task to be performed, Mr. Wilson carried the association through its first struggling year and passed the period of doubt until today it is one of the potent factors in the reduction of deaths in the mines.

Not until the first gathering of the operators and engineers from different localities throughout the country had any of the members of this new association realized the great importance of the movement. It is difficult to measure in terms of lives saved the work accomplished

by this association through the efforts of its pioneer, Mr. Wilson. We can only take the evidence adduced from the members who declare that as a result of their getting together and their discussions, many of the mines throughout the country have taken a new and much more intelligent interest in both rescue and first-aid work, and that the movement is extending in a more rational way throughout the country.

It does not require much imagination to realize that in the coming years many miners may be spared to their families through the good accomplished by this association, which started with the idea of Herbert Wilson. If as someone has said, the mine rescuers are "soldiers of humanity," Herbert M. Wilson is one of the great leaders in this humanitarian army. Mr. Wilson is a member of the American Society of Civil Engineers and of several other technical societies.

In connection with these activities and especially with the Bureau of Mines, he is already well known by those in the mining industry who are concerned in safety and rescue work in mines.

Herbert M. Wilson was born of English parents in Glasgow, Scotland, Aug. 23, 1860, and came to the United States when but a few months old. He was educated in the public schools in Plainfield, N. J., where he lived until he left college. He took a year's preparatory course in Cooper Union, New York, before entering the School of Mines, Columbia University, from which he graduated in 1881.

His initial professional work was on the designing and construction of the first United States Electric Lighting plant, built in New York City; subsequently he spent a few years on railway construction in Mexico. The next 15 years were spent in topographic surveying and in irrigation engineering in nearly every state in the Union. The larger portion of this period was passed in the far West.

This early experience in the organization and management of engineering work and surveying, thrown on his own resources in remote portions of this country and Mexico, were splendid training for his subsequent work in the management and organization of similar enterprises in the technologic branch of the Geological Survey, and in the Bureau of Mines.

A Safety Banquet in West Virginia

SYNOPSIS—The United States Coal & Coke Co. gives its fourth annual Safety-Boosting Banquet to its employees. This banquet is one of the many devices this firm employs to foster the safety morale of its working force.

It has now been several years since the various companies constituent and subsidiary to the United States Steel Corporation began an aggressive campaign for the reduction of accidents to employees. The motto, "Safety First," then launched, has since spread to the four corners of the continent and become the slogan of innumerable commercial, industrial and transportational enterprises.

The fourth annual Safety-Boosting Banquet of the United States Coal & Coke Co., a subsidiary of the steel corporation, was held at Gary, McDowell County, W. Va., Saturday evening, Jan. 10, 1914, with about 175 persons present, of whom approximately 150 were foremen and subforemen of the company, while the balance was composed of state officers, professional men and ex-officials of the company.

A simple but extremely palatable menu was first served, after which the real business of the evening began. Papers were read upon the subjects of Efficiency and the Elimination of Accidents in (a) The Cutting of Coal by Mining Machinery, by J. M. Tulley; (b) The Loading of Coal by the Miner, by W. W. Harding; (c) The Setting of Mine Timbers, by W. P. Kearns; (d) The Transportation of Coal by Motors, by A. N. Harris; (e) The Handling of Supplies, by C. G. Seaton. Papers were also read upon the following subjects: The Prevention of Gas or Dust Explosions, by J. R. Booth; The Feeding of Live Stock, by H. T. Graham; The Care of Live Stock, by G. A. Wilson; Efficient Ventilation of Mines with a View to Eliminating Accidents, by A. G. Hahn; The Inspection of Mines with a View to Eliminating Accidents, by J. L. Mullen; Efficiency in Mining Engineering with a View to Eliminating Accidents, by H. W. Saunders; Efficiency in Mechanical Engineering with a View to Eliminating Accidents, by R. H. Davis; Efficiency in Electrical Engineering with a View to Eliminating Accidents, by Eli Clemens; Statistics on Results Accomplished in Accident Prevention, by H. N. Eavenson.

The hall in which the banquet was held was simply yet tastefully decorated with boughs of evergreen and rhododendron, also the national colors, while safety mottoes were conspicuous. In the front of the hall, facing the audience, was the representation of a mine heading, illustrating the system of timbering adopted by the company. As a special feature of the banquet the foremen's Honor Table was provided, at which were seated 17 foremen and assistants who had a record clear of fatal or even serious accidents for at least six months. Some had a clear record for as long as 26 months.

In order to give these officials an incentive to be constantly on the alert for dangers which may cause accidents, the company gives a premium to each of its foremen and assistants, each month, for a clear accident record. Of this premium system, as well as other means employed by this company to eliminate accidents, COAL AGE will have more to say in an early issue.

Among the guests present were Messrs. Earle A. Henry, Chief of the State Department of Mines, Lawson Blenkinsopp, district mine inspector, also attorneys at law, coal operators, representatives of the public and technical press, etc.

Unfortunately, Gov. H. D. Hatfield was unable to attend the festivities, being detained by other important business. He, however, telegraphed his regrets, and forwarded a letter reading in part as follows:

To the officials of the United States Coal & Coke Co., in banquet assembled:

I feel that I would be deeply lacking in the sense of appreciation of services well done did I not take advantage of this opportunity to extend to you my heartiest felicitations upon the unprecedented strides made by the United States Coal & Coke Co.'s officials for the protection of human life.

I trust that your activities in the precautions taken against the hazards of the mining industry will continue to the extent of maintaining you in the position you now occupy in the fore rank of those great companies which hold as their guiding motto "Safety First," and which have demonstrated the practicability of that ideal.

The day has passed when it can longer be contended that precaution in the mining industry is impractical—that it is too expensive to look after the welfare of humanity—and to General O'Toole and the other officials of the United States Coal & Coke Co., recognized pioneers in the movement for the prevention of accidents in coal mines, the people of our state owe an everlasting debt.

A persual of reports shows me that you have an average tonnage of 476,454 for each fatality in the mines at Gary, your record standing out in sharp contrast to the general average in McDowell County, which shows the fatality tonnage to be 141,582. I know that some real work has been done to make such a remarkable record as this, and I trust that you will continue to strive to reduce the mining danger to an actual minimum.

I am endeavoring in connection with my daily duties to keep in touch with the conditions of every mine in the state, through reports submitted by the various inspectors of the state mining department. One of the greatest achievements that I would like to bring about during my administration as governor is a material reduction in the death toll as well as the lessening of the number of accidents in the mines of West Virginia.

I recognize the magnitude of your coöperation to this end and the movement for the protection of life as promulgated at Gary is being reflected over all mining sections of the state. It has served to put the protection of human life in the mine within the vale of possibility.

On the whole, our state does not at this time show up creditably with other coal-producing regions when we analyze the fatalities that occur each year. Many causes are given for the terrific death toll. One of the most salient of these is the fact that West Virginia is a new mining state and the development of its coal resources is being carried on extensively at present and in the opening of new mines, new dangers are always lurking. I believe that through a system of education and instruction, whereby the miners may learn to protect themselves, that we will be able to lessen accidents to a marked degree. This you have succeeded in doing at Gary.

Miners and operators alike in West Virginia, I believe, are awakening to the fearful death toll in the mines. This awakening is necessary to reform and this I believe we will soon experience. Such affairs as this in which the means of accident prevention are discussed is one of the best ways to spread the propaganda of safety to every mining community of the state.

I want to assure you of my hearty interest in the continued success of the model mining operations at Gary, and nothing will be a greater pleasure to me than to give my coöperation to your plans for accident prevention.

I reiterate my regret at being unable to be with you on the occasion of your annual banquet. I bespeak for the officials of the company the greatest degree of success, and for that success the thanks of a grateful people.

(Signed) H. D. Hatfield.

Charleston, W. V., Jan. 9, 1914.

While the progress in accident prevention for the year 1913 was not as great as was hoped in its beginning, yet a steady progress since the campaign for safety was begun was revealed by the statistics presented. The figures for the year show an increase in tons of coal produced per fatal accident underground over those of 1909 of 250 per cent.; over those of 1910, 130 per cent.; over 1911, 68 per cent., and over 1912, 12 per cent. The number of tons of coal produced per fatal accident, both under and above ground, during the year 1913 showed an increase of over 25 per cent. over those of the preceding year.

During the first months of 1913 no fatal accident occurred, and 1,034,000 tons of coal were shipped. No. 6 works of this company has run 18 months without a fatality. During that time only one serious accident has occurred. This shows that 750,000 tons of coal have been produced and shipped with only one serious accident—a broken leg.

We have long been accustomed to hearing the mines of England and Belgium spoken of as being the safest in the world. The actual records show that the workings of the United States Coal & Coke Co. have a lower death rate than the mines of either of these foreign countries. It will doubtless be a surprise to many people to learn that the death rate in these mines is, per thousand men employed, approximately one-fourth that prevalent among the Gloucester fishermen, and closely approximates the average among the farmers of the country.

Great as have been the strides made in accident prevention in these mines, the end is not yet. No one knows or can guess the actual minimum in the death rate among coal miners from accidental causes. It is the fondest desire and the firm determination of the management of this company to render its mines not only the safest in the United States, or the world, but the safest which human intelligence and persistence can secure.

COLLIERY NOTES

Rivets are not a trustworthy method for securing the gauzes of safety lamps.

There are now five central rescue stations in working order in South Wales and two others in course of formation.

It is satisfactory to find that, notwithstanding the great strides which electricity has made as the hand-servant of the mining engineer, very few accidents are traceable to its use.

In legislating for industrial safety, it is a sound principle to forbid dangerous practices when such a restriction does not thereby entail undue hardship to the community, or, in other words, when the remedy would not prove worse than the disease.

The total coal reserves of the world, compiled from all the reports received, amount to 7,397,533,000,000 tons, of which amount nearly 4,000,000,000,000 are bituminous coals, nearly 3,000,000,000,000 are brown coals of various grades, and about 500,000,000,000 are anthracite.

In selecting a coal-cutting machine, the question of the weight of the machine is one deserving careful consideration. Where the holing is easy and a deep undercut is not required, a light machine will do the work without undue vibration, and it has the advantage of being easily and expeditiously handled, but where deep, heavy work is required, 70 cwt. is not too great a weight for the machine.

The Transition from Inflammation to Explosion of Coal Dust

SYNOPSIS—An explosion is not merely a culmination of progressive combustion but a suddenly developed phenomenon, when the coal as a whole enters into chemical reaction and would so act, even if it did not contain any hydrocarbons. This develops such a center of force that a wave of pressure backs on the zone of inflammation, producing those effects previously ascribed by most writers to suction.

The Altofts gallery, in which the experiments about to be described were conducted, and the instruments employed for determining the necessary data, have been fully described in the "Record" of the Mining Association. It will, therefore, only be necessary here to give a brief account of the manner in which the experiments were made.

The explosion-tube or gallery, as previously stated, was 600 ft. in length and 7½ ft. in diameter. One end was open, and at the other a second tube, 6 ft. in diameter and 158 ft. long, formed a right-angle bend. Then followed short lengths of tube of 6 ft. in diameter, forming a zigzag connection to a chamber in which a ventilating fan was installed. At each angle formed by the zigzag relief valves were hung, and two swing doors were attached on either side of the fan chamber. The general arrangement is shown diagrammatically at the foot of Fig. 1.

The coal dust, obtained by pulverizing nut coal, was spread evenly by hand in the quantity required on the floor of the explosion tube and along wooden shelves, 5 in. wide, five of which, fixed longitudinally above each other on each side of the gallery, extended the whole distance required for the experiment.

Ignition was effected by the firing of a charge of 24 oz. of blasting powder, with 8 in. of clay stemming, from a cannon, pointing toward the open end of the gallery and inclined upward at an angle of about 35 deg.

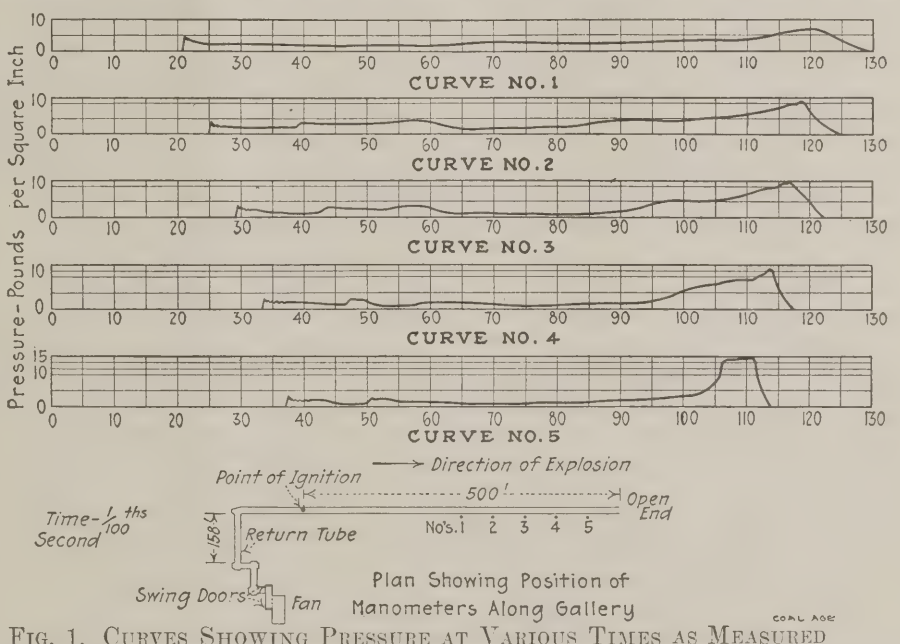


FIG. 1. CURVES SHOWING PRESSURE AT VARIOUS TIMES AS MEASURED BY FIVE MANOMETERS. THE PRESSURES PRIOR TO THE 81ST HUNDREDTH OF A SECOND SHOW THE EFFECT OF CONCUSSION ONLY

THE DUST-RAISING CANNON

A rapid air current was drawn through the gallery at the time of the experiment for the purpose of raising the coal dust into suspension. This suspension of the dust cloud was also partly effected by the concussion produced on firing a small cannon charged with 4 oz. of blasting powder and stemmed with 3 in. of dry clay. This "cloud-raiser" was placed 100 ft. toward the open end of the gallery from the point of ignition; it pointed against the side of the gallery and no coal dust was strewn near it.

DRAFT CONDITIONS

The experiments were carried out in the following manner. The coal dust having been strewn in the gallery and the cannons charged, the ventilating fan was started, both the doors in the fan chamber being wide open so that no air current was drawn through the explosion tube. As soon as the speed of the fan had attained that required for the experiment, these doors were closed by a cord controlled from the firing station, and the air current was thus drawn through the open end of the gallery. The doors when closed completed an electric circuit, which rang a bell in the firing station, and started a seconds clock. Six seconds after the closing of the fan doors the "cloud-raiser" was fired, and the "igniter" was fired two seconds later, the charges in both being ignited electrically.

The explosions as thus produced can be regarded as taking place in a tube open at one end and closed at the other, for the right-angle bends at the fan end of the gallery greatly retarded the release of pressure and had the general effect of a closed end.

THE AIR CURRENT WEAK AND ITS DIRECTION UNCERTAIN

The fact that the explosive mixture of dust and air had an initial direction of movement contrary to that of the explosion under investigation can be disregarded, for the disturbance accompanying ignition by the cannon reversed the direction of the air-current, which was moving at a speed of about 17 ft. per sec. only. The effect of the air current was, chiefly, to create a more or less homogeneous mixture of dust and air at the moment of ignition.

Note—Second abstract from the fourth report by the British Explosions in Mines Committee on coal-dust explosions. The first abstract was printed in our issue of Jan. 3, Vol. 5, pp. 19-21, under the title, "Concussion as a Cause of Explosions."

Explosion Doubtless Traveled Both Ways

In describing the experiments made under these conditions, attention will mainly be directed toward what took place between the point of ignition, the position of which along the gallery varied, and the *open* end of the gallery. The fact that inflammation could also travel toward the fan for a certain distance, dependent upon the position of the igniter, must not, however, be overlooked, for there is no doubt but that the pressure thereby produced would affect, to a certain extent, the records obtained of the explosion developed in the opposite direction.

In the experiment now to be described (No. 119, June 9, 1910), which is typical of many similar ones, the point of ignition was 500 ft. from the open end of the gallery, and, therefore, 100 ft. from the junction with the return to the fan. The coal dust was spread on the shelves and floor at the rate of 1 lb. per linear foot, equivalent to 0.4 oz. per cubic foot of air space of the gallery.

This quantity of coal dust, 0.4 oz., is about four times as much as is required for the complete combustion, to form carbon dioxide and steam, of the oxygen in one cubic foot of air. It was the quantity used throughout the experiments recorded in this report.

Pressures Measured Continuously by Five Manometers

At a distance of 250 ft. from the point of ignition a manometer, or time-pressure recorder (No. 1), was fixed. Four other manometers were also set along the gallery at distances of 300, 350, 400 and 450 ft., respectively, from the point of ignition, No. 5 thus being 50 ft. from the open end of the gallery, as shown in the diagram at the foot of Fig. 1.

Each manometer was provided with a drum revolving at a uniformly rapid speed, so that each gave a continuous record, during the whole time the experiment lasted, of the pressure existing at the particular point along the gallery at which it was placed. Each time-pressure chart was thus a curve in which the abscissae represented times and the ordinates pressures. The principle was, in fact, similar to that of an ordinary barograph.

The series of curves in Fig. 1 are reproductions of the charts thus obtained, the charts being synchronized from the records of pairs of electro-magnetic styli marking on each, one of the pair on each instrument recording the time of ignition and the other showing the speed of revolution of the drum of the manometer.*

The unit of time used in reproducing these curves is $^1/_{100}$ of a second, $t = o$, being the time of ignition, that is, the time when flame issued from the mouth of the igniting cannon. The unit of pressure used is 1 lb. per square inch.

The Concussion Wave

The first indication of pressure shown on each curve is that due to the concussion wave caused by the firing of the 24 oz. of blasting powder used to effect ignition. This concussion wave travels, as might be expected, with a velocity approximately that of sound in air at ordinary temperature and pressure. The pressure due to the concussion wave, therefore, appears on each manometer record in succession after an interval of time, dependent upon the distance of each manometer from the point of ignition.

For example, in curve No. 1 (Fig. 1) the period that elapsed between the time of ignition ($t = o$) and the first indication of pressure was 20.8 hundredths of a second. The distance from the point of ignition of the manometer that traced this curve (manometer No. 1) was, as stated above, 250 ft. The speed of travel of the concussion wave from the igniting cannon was, therefore, about 1200 ft. per second.

Similarly, the manometer fixed at a point 300 ft. from the point of ignition (manometer No. 2) began to indicate pressure 25 hundredths of a second after the cannon was fired; and so on, each manometer in succession beginning to function 4.2 hundredths of a second after the preceding one, their distance apart being 50 ft.

The Pressures Directly Due to the Firing of the Cannon

Separate experiments were made with the gallery free from coal dust to determine the magnitude and duration of this "igniter pressure" alone. They showed that when the igniter was placed 500 ft. from the open end (the same position that it occupied in the coal-dust experiment, of which the curves in Fig. 1 are records); curve No. 1 recorded a maximum pressure of 4 lb. per square inch, which appeared 21 hundredths of a second after the cannon was fired and fell gradually to zero after 81 hundredths of a second.

The pressure due to the igniter alone, as registered at manometer No. 1, lasted, therefore, 60 hundredths of a second. Curve No. 5 recorded a maximum pressure of 3 lb. per sq.in., which appeared 37 hundredths of a second after the cannon was fired and fell to zero after 60.5 hundredths of a second. The intermediate curves, Nos. 2, 3 and 4, gave intermediate values.

When considering the curves obtained during the coal-dust experiment No. 119, therefore, it is possible to divide each into two portions. The portions representing conditions prior to the 81st hundredth of a second show the effects of the concussion wave from the igniting cannon; it will be seen that they are all much of the same type. The portions exhibiting the pressures after that time represent the effects of the inflammation of the coal dust.

It is interesting to note that the curves Nos. 2, 3, 4 and 5 record the effect of the concussion wave (from the cannon) which traveled to the "closed end" of the gallery and was reflected back toward the open end. This is shown at time interval 38.5 in curve No. 2, and at time intervals 42.5, 46.5 and 50 in curves Nos. 3, 4 and 5, respectively. This "reflected wave" was traveling at a speed rather faster than that of sound in air at ordinary temperature and pressure.

In curve No. 1 the "igniter pressure" had just died away at the end of 81 hundredths of a second, and from that time onward the pressure developed was due solely to the combustion of the coal dust. The maximum pressure attained is not very great, nor is there any sign of a sudden increase. The same can be said of curves Nos. 2, 3 and 4.

Where the Explosion Occurs

Curve No. 5, however, which recorded the pressure existing at a point 450 ft. from the point of ignition, presents a different case. A rapid increase of pressure oc-

*Full details of the construction of the manometers and of the manner of obtaining the records are given in the "Record" of the Mining Association (Chapter V).

curs 106 hundredths of a second after the time of ignition, the pressure rising from 8 to 14 lb. per square inch in 6 thousandths of a second. The pressure then gradually increases to a maximum of 16 lb. per square inch, which is maintained during a short time and then falls fairly rapidly to zero as release is obtained at the open end of the gallery.

The Pressure Travels Inward

This sudden rise of pressure about 50 ft. from the open end of the gallery sends an impulse traveling back toward the closed end, where the pressure was previously comparatively low. For it will be seen that each of the curves Nos. 4, 3, 2 and 1 shows signs of a similar rise of pressure toward its end, the order in point of time in which these "peaks" make their appearance showing that the impulse is traveling along the gallery from the open end toward the closed end; that is to say, in an opposite direction to that of the inflammation.

The progress of the inflammation, as indicated by the pressure developed, is perhaps more clearly shown by the curves in Fig. 2. These curves have been prepared from those in Fig. 1, each separate graph representing the state of pressure along the gallery, over the distance lying between the first and the last manometer, at successive hundredths of a second beginning 95 hundredths of a second after ignition. Pressures are represented by the height of each part of each curve above its base line.

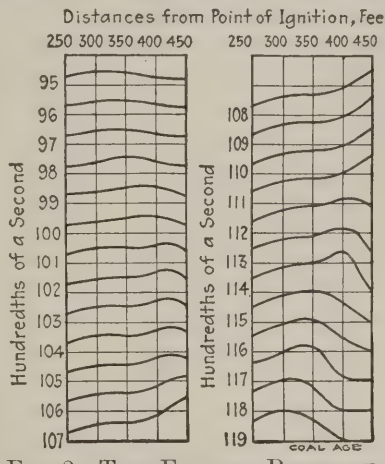

Fig. 2. The Flux of Pressure

A series of 25 diagrams showing separate pressure readings at 25 periods of time exhibiting, as in a moving picture film, the variations of pressure. The pressure summit at 0.95 sec. is at the manometer at 350 ft.; at 1.06 sec. it has moved to 450, at 1.19 sec. it has traveled back to 300. Thus the balance of pressure is first outward, then inward.

A Diagram Showing Relative Pressure at 25 Successive Instants

By comparing these successive diagrams one with another, the progress of the inflammation along the gallery can be studied; for each successive diagram, as the eye follows them in order, represents a pressure condition one-hundredth of a second later than the previous one.

On examining the successive diagrams, the manner in which the region of maximum pressure changes in position, traveling toward the open end of the gallery, can readily be seen. A sudden increase in the steepness of the curves appears between time intervals 106 and 107 (i.e., between 106 and 107 hundredths of a second after ignition); while the release of pressure between time intervals 110 and 111, followed by the movement of an impulse toward the closed end, is well marked.

Some idea can also be obtained from the curves in Fig. 1 of the speed of travel of the inflammation along the gallery. At time interval 95, the maximum pressure was at a point 350 ft. from the point of ignition; by the time the maximum is indicated 50 ft. further on, 6 hundredths of a second have elapsed, so that the speed of travel over that 50 ft. was about 830 ft. per second. Similarly, the average speed over the next 50 ft. was about 1000 ft. per second.

The Increase in Pressure Is Far Greater Than Proportional to Distance Traveled

Neither the speed of travel nor the maximum pressure attained can be called great. There is, however, a progressive increase in both as the inflammation proceeds toward the open end of the gallery. A comparison of the maxima recorded at different points along the gallery, as determined from Fig. 1, shows very clearly the cumulative increase of pressure with increased travel:

RELATION OF PRESSURE TO TRAVEL OF EXPLOSION

Distance from point of ignition, ft.	Maximum pressure, lb. per sq.in.	Increase per 25 ft. travel, lb. per sq.in
350	4.5	...
375	5.5	1.0
400	6.5	1.0
425	10.0	3.5
450	16.0	6.0

In the foregoing experiment what has been defined as "explosive combustion" had just begun after the inflammation had traveled about 425 ft. This is deduced from the fact that a sudden access of pressure at that point is indicated on the curves, previous experiments having shown that a sudden access of that nature only occurs when the combustion of the dust takes place as a whole.

The Gas Propagation Theory of Coal-Dust Explosions Not True

The idea seems to have been prevalent that the percentage of volatile constituents that a particular coal dust contains is a direct measure of the explosive properties of that dust.

The explanation usually given for this assumption is that the gases derived by distillation of the dust by the source of ignition are the real agents in propagating combustion. According to this view, distillation of inflammable gas must first take place, and it is that gas mixing with air that forms the "explosive mixture." Hence it is concluded that any dust that yields only a small proportion of inflammable gas on heating, or from which the gases are driven off with difficulty, should give only moderate explosive effects; and a dust that yields no gas at all should, according to this view, be incapable of propagating explosion.

Neither of these two assumptions is upheld by experiment. A coal dust containing 16 per cent. of "volatile matter" caused an explosion as violent as one containing 35 per cent., while wood charcoal produced an explosion as great or even greater.

Carbon "Gas"

In our view there is nothing to conflict with the belief that coal dust, when suspended in a sufficiently finely divided state in air, acts somewhat like a "coarse" gas, the aggregate of molecules contained in the one particle of dust corresponding to the single molecule that takes part in an explosion of a combustible gas and air, the heat energy necessary for propagation of explosion being derived from combustion of each dust particle as a whole without any appreciable preliminary distillation of gas therefrom.

In other words, heated oxygen molecules coming into collision with the combustible dust particles, form highly heated carbon dioxide and steam molecules, which, in

turn, transfer their energy, directly or indirectly, to other oxygen molecules and unburnt dust particles and so propagate the flame. According to this view, any finely divided dust which can be burned is capable of propagating explosion.

Distillation of Gas Is Slow

Many considerations favor this opinion. The rapidity with which explosive combustion (as distinct from inflammation) is propagated in coal-dust and air mixtures is hardly compatible with the notion that distillation of gas must necessarily first take place, and that it is the heat energy derived from the combustion of that gas which is chiefly responsible for the explosive effects. Such a distillation requires an appreciable time and absorbs energy.

If, in the propagation of flame, the time required to raise the dust and air mixture to the ignition temperature allows appreciable distillation to take place and the inflammable gases thus evolved are burnt in preference to the entire dust particles, then analysis of the products of explosive combustion should afford proof of it.

Preferential burning of the "volatile constituents" of the coal dust would result in the production of a smaller proportion of permanent gases (carbon dioxide and carbon monoxide) than would be given by combustion of the dust particles as a whole; for the "volatile constituents" contain a larger proportion of hydrogen than does the whole coal substance.

An Explosion of Dust Produces Proportionally Less Steam Than Would an Explosion of Its Gas

No evidence has been obtained of such a preferential burning of the "volatile constituents" in those experiments where *explosive combustion* has been attained. On the contrary, the gases withdrawn (just after the flame has passed*) have always shown a ratio

$$R = \frac{oxygen\ present\ as\ oxides\ of\ carbon}{oxygen\ present\ as\ steam}$$

in agreement with the ratio required for combustion of the dust particles as a whole, as determined from the chemical composition of the dust.

Samples withdrawn during the preliminary period of comparatively slow *inflammation* do indeed show that in this stage, there is a preliminary distillation of gas from the dust, and, as explained in a previous report; it is the ease with which such distillation is effected that mainly determines whether a particular dust is capable of propagating *inflammation* more or less readily.

The Sudden Rise in Pressure

The transition from comparatively slow inflammation, during which distillation of gas takes place as a preliminary to burning, to explosive combustion, during which each dust particle that aids in propagating the flame is burnt as a whole, appears to be well defined. It is characterized by a sudden rise of pressure, the change from low to high pressure taking place as the flame travels only a few feet of distance (see curve No. 5, Fig. 1). When no such "peak of pressure" occurs, as, for example, when the distance of travel has been insufficient, analysis of the products of combustion shows that preferential burning of the volatile constituents of the dust has taken place; after this rise of pressure has occurred no such preferential burning can be detected.

It is for this reason that we consider it necessary to draw a line of demarcation between "inflammation" and "explosive combustion" of coal dust and air mixtures, the difference, though mainly, of course, one of degree of rapidity of combustion, being also one of character.

*Subsequent to the passage of the explosion along the gallery, the heated products of combustion effect the distillation of gas from excess coal dust—coal dust which has not assisted in the propagation of flame—and if an auxiliary supply of air enters the gallery and mingles with this gas, a secondary explosion (of gas and air) may take place.

Annual Meeting of A. I. M. E.

The annual meeting of the American Institute of Mining Engineers will be held Feb. 17-20, 1914, at its headquarters, 29 West 39th St., New York City. All indications point to a very active and important meeting. Several interesting coal papers will be presented. Alexander Bowie will read a paper entitled, "The Burning of Coal Beds in Place." F. Donaldson is to present a paper on "The Injection of Cement Grout into Water-Bearing Fissures." George Otis Smith has a paper on "Disposition of Natural Resources." Another interesting paper will be presented by William Kent, and will deal with "Classification and Heating Value of American Coals."

Canadian Mining Institute

The 16th annual meeting of the Canadian Mining Institute will be held in Montreal, Can., Mar. 4, 5 and 6. The headquarters will be the Windsor Hotel. Among the many papers already promised are the following, which should be of interest to coal men: "Factors Influencing the Cost of Power for Mining Purposes," by J. M. Forbes, of Montreal; "Mining in British Columbia," by Howard W. Dubois, of Philadelphia, Penn.; "Coal Resources of the World," by D. B. Dowling, of Ottawa, Can.; and "Safety in Coal Mines" (illustrated by moving pictures), by a representative of the H. C. Frick Coke Co.

BY THE WAY

It is easier to be critical than to be correct.

In the spring the miners' fancy lightly turns to thoughts of strikes.

Applause is the spur of noble minds, the end and aim of weak ones.

Where doubt is, there stands truth, for doubt is the shadow of truth.

The man who has two strings to one bow may shoot strong but not straight.

Every man loves justice at another man's expense; few care for it at their own.

A "hard-boiled" (derby) hat is one of the best protections there are against the mine trolley wires.

Let a defect, which is possibly small, appear undisguised. A fault concealed is presumed to be great.

They say that money talks. Judging from the commotion out in Ohio coal fields it must be getting ready to say goodby to someone.

Editorials

What Your Coal Is Worth

It will perhaps create some opposition to state that the owner of the mine usually realizes better than his superintendent and his foreman what his coal is worth. It is this knowledge which makes the operator so keen about coal waste and so excited about the suggestion of a squeeze.

To most men the value of the coal in the hill is the sum of the prices paid for the coal area, divided by the number of tons thus purchased. To the business man the value is far greater. Before a coal property is bought at perhaps as little as $25 to $50 per acre, the company making the purchase often spends on surveys, drilling and legal expenses five and perhaps more additional dollars for that same unit of area.

These initial expenses should be added to the cost of the coal, and that figure must be increased a certain amount for the value of the improvements, if the coal seam is likely to be exhausted before the mine is worked out. Of very few mines can it be said that their life is longer than the presumed life of the bulk of the equipment.

The coal value must be loaded with this charge. It is true that it is customary to add amortization charges, depreciation and obsolescence to the annual deductions from revenue, and it may be well said that it cannot be also charged against the coal *as coal* in such an accounting. But in investigations to ascertain the question of the appropriateness of certain expenses to save coal, such a method of appreciating coal value is to be approved.

Another charge which is appropriate is one for headings driven and for drainage. The work is already done and has been paid for; to make it of no avail is to waste the money thus expended. Moreover, the wasting of coal involves a hastening of a number of expenditures which might otherwise be delayed. Rail, pipe and electric wire will probably have to be bought in quantity very little different, whether coal is wasted or not, but the time of purchase and the depreciation consequent thereon will be increased if coal is left in the pillars.

In fact, many superintendents who declare that methods such as have been practiced in the Connellsville, Pocahontas, Georges Creek and Fairmont regions would have ruined them, if put in operation in their fields, have already thrown away more heading development than would have sufficed, if economized, to put such methods into effective operation. We have noted old mines where more good heading has been thrown away than would have started two mines in the Pocahontas region along the lines required by the Pocahontas Coal & Coke Co. of all their lessees.

We leave it to our readers to value their own coal correctly. The items are so various that an estimate for mines generally would be misleading, but it must always be remembered that the values bear no close relation to the price paid to the farmer for his land. Railroad cost may be the largest element at some mines, the plant may be the big item at another, and in a third with few improvements and low coal the heading and drifting cost may be the leading item.

The value of coal in the hill is a subject well worthy of consideration, for on its determination depends the successful operation of the mine. Many a man has become bankrupt through his economies.

Nystagmus

It is a remarkable fact, not chargeable, we believe, in any large degree to malingering, that in the British Isles 1819 cases of nystagmus were carried over from 1911 to 1912 and that in the latter year 1376 cases received compensation for the first time.

The disease has spread with startling rapidity in a country where the mining conditions have not markedly changed. The mines have been worked with safety lamps for many decades; for centuries men have lain on their sides and undermined coal. In view of the new development of the disease, neither of these causes can be regarded as reasonable sources of nystagmus though it has often been ascribed to their influence.

If imperfect light is the cause, why does the disease get more frequent as the light given by lamps increases? We have progressed from the firewheel to the Davy and Geordie with their metal-shaded flames and deficient light-insuring draft. From that we have reached lamps with glass cylinders through which the full light of the flame is secured and draft is perfected. We have changed oil for naphtha and in some cases installed electric lamps but, with all our changes, nystagmus appears to have increased.

We believe we are right when we assert that nystagmus is unknown in the United States. If so, why does not nystagmus occur here, for we have safety lamps exactly similar to those which have been accused of doing so much harm in England? Why are the conditions so different across the intervening ocean? It may appear bold to suggest in absence of proof that nystagmus is a germ disease and propagates more freely in deep mines than in those that are shallow. But such an interpretation of the facts appears quite reasonable.

It seems that the depth of the mines and their consequent high temperature is the cause of the ankylostomaisis scourge in Europe. Perhaps their shallowness here keeps the United States immune. However, that disease seems not to spread on the outside of the mines in Europe, while some cases of nystagmus have occurred in others than miners in England. Here, therefore, the parallelism is not complete.

Nystagmus, as an English court has said, is rather a symptom than a disease and in discussions of its character the symptoms rather than the basal disorder are considered. If it were a newly discovered *cause* like appendicitis and not a newly found symptom, we might believe that it existed years before it was listed as an ailment.

But we cannot believe that a *symptom* did so exist, and we must, therefore, favor the idea that nystagmus is of recent origin. Consequently we are justified in our belief that it has rapidly spread and is not an old ailment which merely suddenly sprung into discussion as a result of scientific research and the fostering care of the Workman's Compensation Act.

We can remember how the story that the South was a hot bed of ankylostoma aroused the whole country. It seemed unlikely that a parasite, of which few had even heard and which was unknown at the beginning of the last century had done so much damage to a people as proud and as capable as the mountaineers of the Southern States.

Perhaps we will find that nystagmus is similarly caused, probably, however, not by a nematode, but by some lower organism, and will have a similar spread wherever favorable breeding conditions exist. For the description of nystagmus seems such that we can hardly conceive of it as a disease of the eye, but rather as a muscle or nerve trouble of a specialized kind and of extreme severity, brought on by a specific germ.

The Mining Industry and the Public

Almost all miners live in rented buildings and not in their own homes. While better paid and better housed than the tenantry of Europe, their economic condition is really in no great degree different. Such men have no reserves of any kind. Idleness and penury are with them synonymous, and discontent is inevitable. Nor is the argument that, all men could save if they would, one which appeals with any force. It does but excuse the coal operator morally; as a reasonable being who desires content as an adjunct to successful industry and as an assurance against syndicalism, the sense that he is *morally* justified is not sufficient.

The new propaganda for the destruction of capitalism of all kinds will be fostered by our creating large aggregations of people who have no reserve capital, who after periods of comfortable living are by reason of strikes and industrial irregularities frequently plunged into the most bitter poverty. The "new unionists" declare such people have "nothing to lose but their chains." They have indeed something to lose, to wit, that industrial activity and the advantages created by the accumulated capital of many years which make possible the cheap production of articles of utility. Let either be destroyed, the earning power of all of us is reduced to a minimum.

But they have no capital to lose. In this they are absolutely right, and it is not well for us to forget that in a camp full of workmen, not owning a foot of land, a single stick of timber or a brick, we have a condition which may easily become a menace.

It is true that hitherto there has not been a great demand on the part of miners to furnish their own homes; on the other hand, such a desire as existed has not been encouraged. It has its economic disadvantages, it is true. It has on occasion extended strikes, for men owning their homes are better able to withstand the stress of idleness, especially where they have both houses and farms.

Perhaps temporarily the operator is better off with "tenantry" instead of "yeomanry," if we may transfer and slightly strain those words, but the nation and ultimately the operator will suffer if the stake of the citizens in the prosperity of the nation is reduced. In fact, the coal operator is before all a citizen, a most important citizen, we think, and if he continues to create barracks, however exemplary they may be, he will help to form a new United States, composed of two classes only—the plutocrat and proletariat.

No nation has been successful long without a middle class. It may have failed to recognize that it had a linking body of citizens, but they were there nevertheless.

These facts are given emphasis by the Indianapolis convention, where the United Mine Workers of America entertained a resolution opposed to the militia, which is used to protect property such as the mine workers, for the largest part, do not possess. The modern unionism and the new industrialism join in condemning the militia and the state constabulary because they prevent acts contrary to the law. They do not desire a reform of these bodies, but oppose their very existence.

In Europe the same condition exists. Tom Mann served nine months in jail for endeavoring to seduce the military forces of Great Britain, and in France the syndicalists have paid a stipend to every soldier in the army, a sort of bribe to keep him friendly to their aims and considerate to them in the breaches of the law which they quite openly advocate.

Let the operator remember that every town of tenantry is a menace to the body politic, which he should strive to convert into a village of homes as rapidly as he can.

The Ethics of the Mine Cave Problem

A remarkable suggestion, according to the Scranton (Penn.) press, was made at the annual meeting of the Board of Trade of that city, Monday evening, Jan. 19, 1914, and promptly adopted with but a single dissenting vote.

The author of the suggestion, "speaking as a mining engineer of forty years' experience," is quoted as stating that the city has suffered a depreciation of $25,000,000 in property values by reason of the publicity it has received concerning mine caves.

The suggestion was put in the form of a motion, to the effect that newspapers should be requested to "soft-pedal" the news of mine caves. To the credit of one man, the head of a local coal company, COAL AGE is proud to say, a strong appeal was made in opposition to the motion—a plea for *honesty and integrity* in all business dealings and transactions.

The suggestion, though approved by the Board, will not receive the indorsement of responsible mining engineers, whose ethics are too sound to permit their profession to be disgraced by an acknowledged concealment of facts that concern the public good and safety.

In just and equal dealings of this nature, there is nothing to hide from public print, and we opine that no paper loyal to the reading public will withhold what it is the public's right to know. The time of domination is rapidly passing; and the right of the people to rule has never been more strongly upheld than it is today. Let right prevail; let the interests and the people of Scranton get together and prosperity for the great anthracite valley will be insured.

The Policy of Hush!

A prominent member of the board of trade of the city of Scranton, at the annual meeting today declared that the real estate of the city had decreased 25 per cent. in value because the newspapers gave too much space to mine caves. He presented a motion that the newspapers be requested to suppress all sensational news regarding surface disturbances. The motion carried, only one dissenting voice being heard.—"Scranton Truth," Jan. 19, 1914.

The above news item suggested the following:

What if a settling breaks a main,
Spreading death in the unleashed gas,
Firing the houses in its train,
Burning all to a shapeless mass?
Handle the news with care and tact,
Quite as a decent person should.
Bury the knowledge of the fact;
Keep it mum, for the common good.

Only the fool, with disordered brain,
Still gives vent to the outworn creed
"We are the victims of lust for gain,
Sacrificed to the god of greed."
Only the traitorous and the weak
Dare to tell, to the city's shame,
That which the loyal scorn to speak.
Keep it mum, or you'll soil our fame.

What if the schools and churches fall,
Shattered wrecks on the shaken sod?
These are the things that we ought to call
Signs of wrath from an angry God.
What if the bottom drops clean out,
Letting a city block go down?
Don't go telling the tale about;
Keep it mum, or you'll hurt the town.

What if a flimsy shack or two,
Roofing a litter of dirty wops,
Splits and vomits its frightened crew
After the surface quakes and drops?
Why should a fevered, frantic fuss
Over a thing like that be made?
Can't you see how it injures us?
Keep it mum, or you'll kill our trade.

Kingston Coal Co.'s Improvements

The Kingston Coal Co., at its No. 4 shaft, in Edwardsville, has established a surgical operating room. The intention is to perform operations in this building before moving the patient to a distant hospital or his home. An abandoned storehouse has been reconstructed so as to serve the purpose described. This work alone will cost over $1000.

Surgical Operating Room

The main compartment will be known as the "first-aid room." It measures 22x24 ft. and like the other rooms it has been floored with cement, and the floors, ceilings and walls have been covered with an enamel paint which permits of sanitary cleansing. The first-aid room will contain an operating table, operating chairs, sterilizers and instrument cabinets, all of steel and coated with white enamel. Adjoining this compartment is a bathroom with tub, shower and foot baths, basins, etc., and adjacent to both is a locker and supply room. All fixtures are portable so as to permit moving the furniture for cleaning. The building is heated with steam and lighted by electricity.

One man will be always in attendance and no one else will be admitted as this exclusion is necessary to maintain asepsis. Dr. D. H. Lakes will be summoned as soon as a man is injured in the mines and he will be at the hospital before the man arrives at the surface.

Bathhouses

A description of the washhouse at No. 1 shaft of the Kingston Coal Co. will be of interest, as it is typical of those at other plants of the corporation. There are three rooms, one equipped with baths and two with clothes lockers. In the bathroom are 36 cement bath tubs, 12 basins and 6 showers.

The company is renovating their houses, which are being made spacious and airy and are being equipped with baths. Many of the sidewalks are being paved and the company has taken part in many of the town improvements at its own cost. It is largely through aid given by the coal company that the work of the Visiting Nurse Association has been made so extensive. Eventually a lecture hall for instruction in first aid, mining and other educational work will be built.

Recent Legal Decisions

Assumption of Risk by Miner—A mining company is liable in damages for death of a miner resulting from negligent failure of the company's inspection officers to discover the necessity for timbering the roof from which the rock fell which caused the accident, but there is no such liability if the miner's own work created the dangerous condition, and he remained at work knowing the hazard. (Kentucky Court of Appeals, Cooké-Jellico Coal Co. vs. Richardson's Administratrix, 161 Southwestern Reporter 537.)

Abandonment of Rights Under Lease—A lease in favor of a coal-mining company, giving the company the right to explore for and mine coal, if found in paying quantities, upon certain conditions, did not give the company such vested right in the coal in place as prevents a finding that it abandoned its rights under the lease, though the period within which an ordinary action to recover an interest in land might be brought had not expired. Whether the lease was abandoned depends upon the intention of the company and the surrounding circumstances of the particular case. (Iowa Supreme Court, McColl vs. Bear Creek Coal Mining Co., 143 Northwestern Reporter 532.)

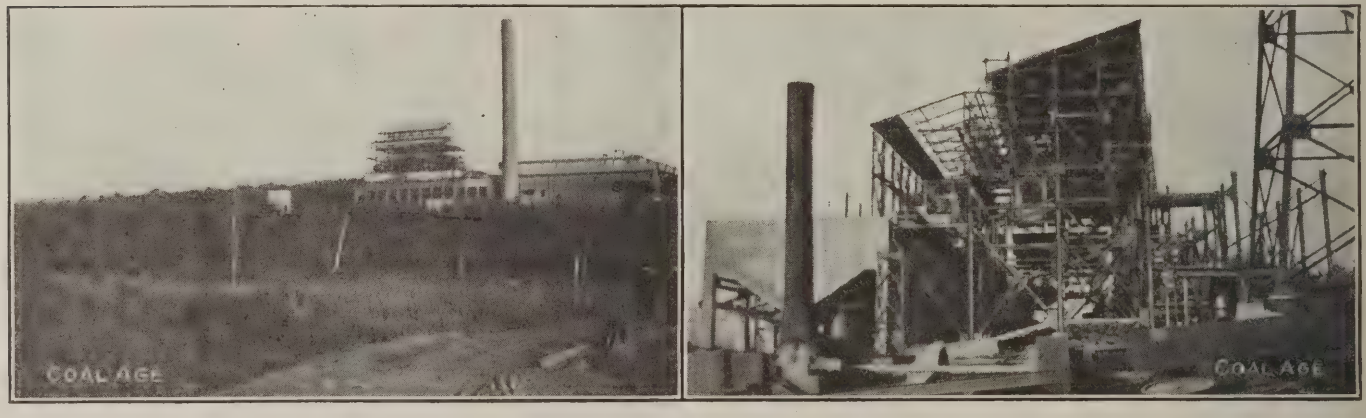
Liability for Injury to Miner—The rule of law that an employer is not responsible for the safety of a place to which an employee's duties do not take him cannot be extended to exempt a coal-mining company from liability for injury to a miner, caused by the fall of rock from a mine roof at a place which he was passing in returning tools borrowed from a co-employee, although the miners were required to furnish their own tools; it appearing that the company knew of, and had not disapproved, a custom of miners to borrow tools from each other. (Iowa Supreme Court, King vs. Mendota Coal Co., 143 Northwestern Reporter 539.)

Effect of Iowa Mine Law—Where the operator of an Iowa coal mine has control of the entries of the mine and certain employees are by custom required to repair any defects in the same, the operator is liable for injury to another employee resulting from negligent failure to keep the entries in a reasonably safe condition; miners being required by the Iowa mine law to prop or support the roof of only such entries as are under their control, respectively. (Iowa Supreme Court, Carnego vs. Crescent Coal Co., 143 Northwestern Reporter 550.)

The Underwood Colliery

The Underwood Colliery of the Penn. Coal Co. at Dunmore, Penn., is expected to be ready for the shipment of coal in the spring of 1914. It is designed to ship 3000 tons of graded coal per day. There are 9 beds of coal of good quality, and it is figured that there is coal sufficient to permit of operation for 50 years. Shaft No. 1 has 4 cageways, and all the coal will be hoisted at that point. Shaft No. 2 is for hoisting men and for an airway. Shaft No. 3 is for the same purposes and for pumping, and lowering supplies. There is also to be a fourth opening, a slope, by which only supplies will be delivered.

UNDERWOOD NO. 3, FOR LOWERING MEN AND MATERIAL, FOR PUMPING AND VENTILATION



Twenty double houses are being constructed to house 40 families. The street on which they front is paved, and each house will have a sidewalk and shade trees. The rooms will be lighted by electricity. Each half of each double house will have 6 rooms, a closet and a sink. There will be two bathhouses, one for the women and the other for men. These will be kept clean by a caretaker appointed by the company.

There are 8 single, plastered-frame houses for the foremen. W. A. May is general manager, and W. W. Inglis, general superintendent.

More Rescue Maneuvers

The car of the Bureau of Mines which was stationed for three months at Fairmont, W. Va., has been moved to Uniontown, Penn., and at Revere an abandoned slope has been offered the rescuemen at which maneuvers like those at Chiefton, W. Va., can be practiced. The car is in charge of E. Steidle and C. W. Riggs, the latter being the first-aid instructor. Two rooms in the old Y. M. C. A. building on East Main Street, Uniontown, are being used as training headquarters, and are temporarily equipped with 10 sets of breathing apparatus.

The slope at Revere which belongs to W. J. Rainey, has been fitted for the training work by the bratticing off of a section of the mine about 400 ft. long. In this section a dense smoke and harmful gases will be formed by burning wood. The companies sending teams are the Tower Hill Connellsville Coke Co., Consolidated Connellsville Coke Co., Oliver & Snyder Steel Co., Coal Department, Republic Iron & Steel Co., Coal Department, W. J. Rainey and the Puritan Coke Co.

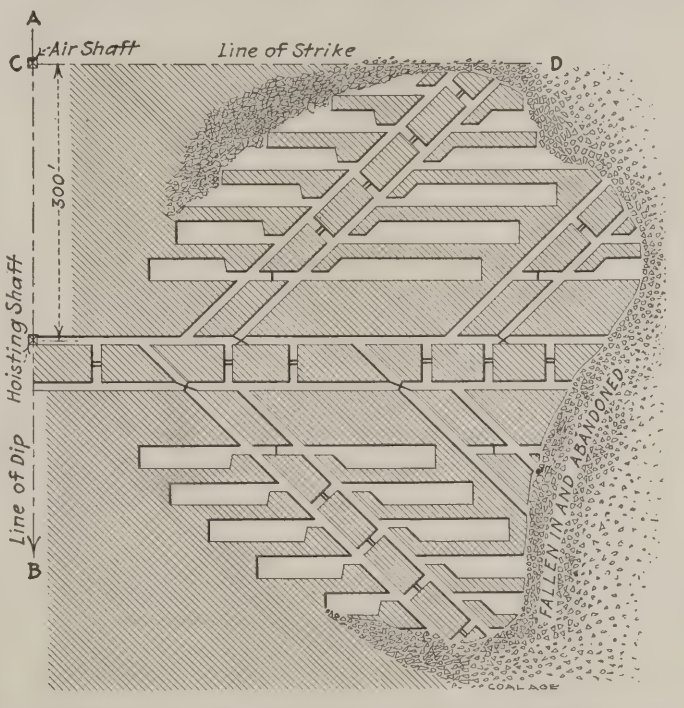
Discussion By Readers

Working Coal under Watery Strata

Letter No. 2—Replying to the inquiry of Geo. MacPhail, COAL AGE, Jan. 3, p. 30, I will answer the questions in the order they are asked, giving my own experience under similar conditions. It may be stated, however, that the data given in the inquiry are scarcely sufficient for the satisfactory solution of a question of so much importance.

The first question asked, If the coal is taken out to such an extent as to break the sandrock, would it be reasonable to expect the same inflow of water as was experienced in sinking the shaft? In reply to this question, I would say that my own experience is that if the roof was fractured only, and no cave took place, although the flow of water might be considerable at first, it would gradually diminish and, in some cases, might cease altogether. The impervious nature of the bed lying above the coal and underneath the sandrock will, in many cases, close the fissures as the strata settles. Should a heavy cave occur, however, the pressure of the water might be sufficient to cause a further fall that may extend to the sandrock. In that case, the inflow of water would probably be as great as that encountered in sinking the shaft. In my opinion, the question of the measures breaking up to the sandrock seems to be a more important matter than the breaking of the sandrock itself.

The second question asked, Would it be advisable to leave in a possible 50 per cent. of the coal as pillars to support the roof, in order to prevent the breaking of the sandrock. In answer to this question, I would advise leaving 50 per cent. of the coal or whatever is necessary for the proper support of the roof. I would suggest that working this seam on the panel system would be advantageous and present opportunities for testing the amount of coal that can be safely taken out in the first working, besides affording ample means of damming off any section in which an inflow of water might occur.



The third question asked, Will the proposed hoisting shaft sunk 300 ft. away from the airshaft make the same amount of water? In reply, I would say should a fault exist between the two shafts, it is possible for the second shaft to pass through practically dry ground, assuming the source of the water supply to lie on the other side of the fault. Otherwise, however, it is probable that the same quantity of water will be met in sinking the second shaft, as in the first shaft sunk. But a sharp rise of the measures toward the second shaft might reduce the volume of the flow.

JOHN E. SPICER.

Cumberland, B. C., Canada.

Letter No. 3—The data given by Geo. MacPhail, in his inquiry, COAL AGE, Jan. 3, p. 30, are so meager, that it will be necessary to make several assumptions, which may or may not be true in his case. However, assuming that no unusual amount of water was encountered before reaching the sandrock when sinking the airshaft, it may be inferred that this stratum is the natural channel for the water entering it at the outcrop or along the line of some geological formation, and that the sandrock bed forms a natural reservoir for whatever water percolates through the overlying strata.

In answer to the first question asked, I will assume that the dip of the seam is in the direction *AB*, indicated by the arrow in the accompanying figure, and the line of strike *CD* perpendicular to the dip *AB*. Assuming, further, that the seam is developed by driving the main entries on the line of strike or parallel to *CD*, and that

ILLUSTRATING SUGGESTION ON DRAWING PILLARS ON THE RETREATING PLAN

cross-headings are turned at an angle to the left and right of the main headings, and rooms are driven off these cross-headings, when the first break occurs in drawing back the pillars on the retreating system, as shown in the figure, an increasing inflow of water may be expected in the dip workings or those lying below the main entries where the break advances toward the rise. On the other hand, a decreasing flow of water would naturally be expected in the rise workings or those lying above the main entries where the line of break is advancing toward the dip.

The reasoning on which I base this opinion is that in the rise workings, the first break would produce the maximum flow of water. Following this, each successive break made in the roof by the retreating pillars, would produce only the water stored in the sandrock directly over that joint. In other words, the first break, occuring to the rise of the pillar workings, would cut off the subsequent inflow of water from the strata higher up the

pitch; while, in the dip workings, the reverse of this is true and the inflow of water would increase with each successive break.

Replying to the second question asked, I would say that since the airshaft is making nearly one-half of the assumed pumping capacity, good judgment would dictate leaving in sufficient pillar coal to support the roof and prevent a cave. If the workings are of any considerable extent, it would only take a small additional inflow of water to overtax the capacity of the pumps and, therefore, any serious break in the sandstone would result in the flooding of the mine. In order to prevent the loss of a large percentage of coal, under the conditions named, it will be necessary to adopt some method of support of the roof that will be equally as effective as the pillar coal left in the first working.

In the working of a thin seam of coal, under similar conditions, we adopted the plan of driving four rooms in a range of 32 yd., leaving a 4-yd. pillar between each range or block. By the time the rooms were driven up their proper distance (75 yd.), this pillar had grown much less. It was necessary to take down roof or lift bottom on the roads; and this material was thrown into the waste on each side of the road, but no particular care was taken to build packs. The roof varied from slate to fireclay in different portions of the mine, and the seam was underlaid with a stratum of hard fireclay interspersed with ironstone. The roof settlement, in this system of mining, was uniform and falls were rare. Even these could have been prevented, had proper care been taken in building packs. In mining a seam of the thickness mentioned by Mr. MacPhail, the waste material produced in driving the entries could probably be used to good advantage in building the packs required in the rooms. The method of culm flushing, as used in the Pennsylvania anthracite region, is worthy of consideration in this connection.

Replying to the third question asked as to whether the proposed hoisting shaft will produce the same quantity of water as the airshaft, permit me to state that, in my opinion, this will depend upon the location of the second shaft with respect to the first. My experience, in this regard, has taught me that if the second shaft be sunk on practically the same line of dip as the airshaft and below the latter it will not make the same quantity of water, for the reason that the water flowing into the airshaft cuts off, in a large measure, the water that would otherwise drain into the second shaft. If, however, the second shaft is sunk to the rise or to one side of the airshaft, practically the same flow may be expected.

I. C. Parfitt.

Jerome, Penn.

Letter No. 4—Replying to the inquiry of Geo. MacPhail, I want to suggest a plan that we have found to work successfully in the gas and oil sandrock in Oklahoma. Although the conditions are somewhat different from those described by Mr. MacPhail, I believe the same method could be employed to advantage in his case also. I have sunk a shaft through quicksand that had to be frozen before we could pass through the stratum. Also, I have seen 14x16-in. oak timber crushed when mining under water-bearing strata.

My suggestion is as follows: If possible, find a basin not far away from the proposed location of the hoisting shaft. Drill a 10-in. hole to the sandrock in this basin and shoot the hole with some high explosive. We use for this purpose about 90 qt. of nitroglycerin, in holes 1200 to 1500 ft. deep. In the present case, the hole being, say 150 ft. deep or less, I would suggest using about 25 to 30 qt. of the explosive. The effect, I believe, should be the same as that produced in our sandrock, which is very hard. The force of the blast should open up the water strata and, perhaps, cause the well to overflow at the surface; but if not, a pump can be used to handle the water and drain the territory in the vicinity of the shaft. The question may properly be asked, Would such a blast shatter the strata between the sandrock and the coal? I do not believe that it would, as my experience is that while this explosive will crack shale, it pulverizes rock and granite, which is of a coarser grain.

In reply to the second question, I would say that, inasmuch as there is a bed of shale beneath the sandstone, interstratified with slate and fireclay, this should be sufficient to keep the water from penetrating to the seam, assuming, however, that proper precautions are taken in mining the coal. Due care should be taken to prevent a cave of, say over 40 or 50 ft. Under ordinary conditions, a shale roof will not cave higher than 30 ft., but will arch over and form a natural support for itself.

The answer to the third question will, in my opinion, depend on the extent to which the drillhole, mentioned, drained the territory in which the shaft is sunk. The manner of shooting this hole is as follows: The explosive is lowered into the hole in cans, by hand or winch, using a double cable fastened to the explosive by a slip noose, so that the cable can be released and drawn from the hole when the charge is at the bottom. The charge is then exploded by dropping a weight or heavy iron bar into the hole. A chisel-pointed bar, called a "go-devil," 4 ft. long and made of 7/8-in. drill steel, is sometimes used. At times, the hole is fired by dynamite, using insulated wires and a blasting battery.

Poteau, Okla.

The Certificate Law

Letter No. 14—I have noted with interest the wide difference of opinion expressed in reference to the mine foreman's certificate, issued in different states. For my part, I fail to see why a man who holds a certificate of competency to act as mine foreman in Pennsylvania, should have to pass an examination in another state before assuming a similar position therein.

A number of arguments have been advanced to the effect that the conditions differ so greatly in the different states, that no matter how good a man may prove to be in the management and control of a mine in one state, he must begin at the bottom and learn the business again, which seems to me absurd. Coal is coal whether here or in China, and the manner of formation of the deposit is practically the same. While some seams may be thicker or somewhat more inclined in one state than in another, it must be remembered that the same differences occur in the districts of a single state. There is the same variety of conditions in the state of Pennsylvania, in respect to coal mining, as exists in any two states in this country. In my opinion, it would be just as absurd to require a man who has been acting as mine foreman in Clearfield County

and desires to take a position as foreman in the Pittsburgh district, to obtain a new certificate before assuming the duties of that position.

Again, many men have gone from Pennsylvania into other states to act as superintendents and are not required to procure certificates and yet they seem to produce good results. In general, the conditions of mining are much the same in one state as another; the mine gases are the same; roof conditions, methods of ventilating and draining the workings; methods of timbering and systems of haulage differ in no material way. In some states, the coal is "shot off the solid"; but that practice is fast disappearing, except in the anthracite region. The greatest difference may be and probably is in the methods of working employed; but no state has a hard-and-fast rule in this regard; and, generally, the mine foreman must work to a plan that has been laid out and adopted by the management.

I fully agree with Mr. Clark, Letter No. 10, COAL AGE, Jan. 10, p. 100, except where he says that a mine foreman should undergo an examination every three years. I would like to ask, what would a doctor, a lawyer or anyone who has passed a civil-service examination think if they had to pass such an examination every three years, in order to keep abreast of the times? I consider that the mine foreman who does not take sufficient interest in his work to keep himself posted on the best means and methods employed in mining, without being compelled to do it through the possible loss of his certificate, is unfit for the position.

THOMAS HOGARTH.

Heilwood, Penn.

Letter No. 15—Referring to the discussion of the certificate law, there seems to me much wisdom expressed in the letters of R. J. Pickett and Geo. N. Lantz, COAL AGE, Dec. 27, pp. 987-8. Of special interest is the suggestion of Mr. Lantz, that certificates be classified according to the classification of mines, and that such classification be made general in the coal-producing states.

In Alabama, we have two classes of certificates; the first applying to mines generating explosive gas and the second to nongaseous mines, which fact implies a similar classification of the mines in this state. It would be manifestly unwise to make a holder of a second-class, Alabama certificate eligible to a similar position in another state, without regard to the gaseous character of the mine, although he would be fully competent to handle a nongaseous mine in any state. Again, the manner of handling gases under various conditions is so similar in all coal mines, that the holder of a first-class Alabama certificate should be qualified to hold a similar position in any state or country. In like manner, the qualifications of a fireboss are practically identical everywhere.

It appears to me that sufficient importance has not been attached, in this discussion, to the part every employer takes in the selection of a mine foreman or fireboss. No employer will risk his property and the safety of his employees by giving a man charge in a mine, before he has fully satisfied himself of that man's knowledge and fitness for the position he is to occupy. He will inquire to ascertain whether his experience has been such as to make him familiar with the conditions he is to handle.

It should be borne in mind that the holding of a certificate of competency is not the supreme qualification of a successful foreman or fireboss. The ability of a foreman to handle men, plan work, think correctly and act quickly in an emergency, as well as his judgment, alertness, industry, soberness, devotion to duty and loyalty to his employer are even of greater importance than the certificate he holds. A man may possess a first-class certificate with a high grade and yet be deficient in many of these essentials. The point I desire to urge is that a man who holds a certificate of qualification, granted in one state, and who is able to satisfy a would-be employer in another state, as to his ability to fill the position successfully, should not be barred by law from taking that position until he has passed a similar examination in the state in question. Such requirement works a hardship on the man and handicaps the employer in his attempt to secure an efficient foreman or fireboss.

It is a fact that many a competent man hesitates to give up a position in one state, upon the offer of a higher position in another state, because of the risk he takes in being able to pass the required examination. Attention has been drawn frequently to the fact that many of the best and most successful mine managers and foremen had little or no early education; but by diligent study and application, they have risen to a position of responsibility. Such men are ill equipped to solve offhand many of the purely theoretical problems required in an examination; and many of these problems rarely confront the mine foreman, in actual practice.

It should be remembered that the most practical mine foremen and firebosses today are studying the actual problems involved in their work. Their spare time is largely devoted to the reading of mining journals and other literature that will keep them fairly well informed on occurrences and abreast with the times in respect to mining practice. It is rare that much of this time is spent in brushing up their mathematics. Again, the excitement and uneasiness that usually take possession of a man in an examination on which much depends, prevents him from doing his best work. Under these conditions, he will often make mistakes that he would not make under other conditions.

I have in mind a successful mine official whose great est misfortune was that his early education was deficient; but, by means of a correspondence course and hard study, he obtained a sufficient knowledge of mathematics to enable him to pass an examination with a high percentage mark. He has been since that time preëminently successful and is considered by all who know him best, including his present employers, as the best all-around mining man in the state. However, in the absorption of his duties, he has forgotten what mathematics he knew, and today would be unable to pass an examination, as he could not solve a simple triangle, without reference to his handbook. The fear of failing to obtain a certificate in another state has kept this man from accepting positions at higher salaries outside of his own state.

In most cases, it is idle to say that if a man is truly ambitious, he will study sufficiently to pass the examination required for the position he desires. Most men will refuse to "cram" *today* for an examination, and to study to remember things that they will not use again and forget *tomorrow*. We must take men as they are and not as we think they ought to be. I may add that

the limitation of a practical man's employment to a single state is not his loss alone, but one that affects the mining industry in all states. A classified universal certificate, or interchange of certificates between states, would benefit all concerned.

WM. KELLUM, Sup't.,
Southern Coal & Coke Co.

Glen Carbon, Ala.

The McAllister Experience

In reading the discussion on Retarding Ventilation when Firing, COAL AGE, Jan. 17, p. 122, I was surprised and disappointed to find that Mr. Paul should speak so disparagingly of the narrated experiences of Mr. McAllister, who conducted a series of experiments in a Kansas mine a few years ago. The experiments were fully described in a number of letters in COAL AGE, a year ago; but the letter to which Mr. Paul particularly refers, COAL AGE, Vol. 3, p. 25, describes a remarkable experience in the rescue of men after an explosion.

To throw doubt on *all* of Mr. McAllister's experiences and statements; because he said that he found "a small tunnel of air traveling in the center of the entry," is, to say the least, in my opinion, ill-advised and unwarranted. We may reject Mr. McAllister's conclusions, but nothing is gained by disregarding facts that are evidently true. Also, we are compelled to admit that this man has rendered valuable service in his investigations of the phenomena of mine explosions. In my opinion, he has shown himself to be a courageous, observing, practical miner, who has repeatedly risked his life in attempts to ascertain the true facts. Because he may have failed, in a scientific sense, to express correctly his meaning is no excuse for discrediting his statements.

After any mine explosion, there is bound to be a reflex movement of the air in order to bring about an equalization of temperature throughout the entry. As Mr. McAllister entered the mine immediately after the explosion, this reflex movement of air, which was especially marked along the bottom or floor in the center of the entry and which I have often myself experienced, was probably more pronounced under the conditions existing in that mine, than anything observed by Mr. Paul. In his description, Mr. McAllister does not state that the air traveling in the center of the entry was "pure," as Mr. Paul quotes him; but, in his rescue of the men, he proved that this air would sustain life and permit strenuous bodily exertion at the same time.

JOHN VERNER,
Ex-Mine Inspector.

Chariton, Iowa.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

Example—To show the effect of natural air columns in fan ventilation, assume a shaft mine ventilated by means of a fan; the seam is practically level; the fan shaft is 800 ft. deep and the hoisting shaft 600 ft. deep.

(a) Assume the fan is exhausting and produces a circulation of 200,000 cu.ft. of air against a water gage of 2 in., in the winter when the outside temperature is 30 deg. and that of the mine 60 deg. F., and calculate the resulting water gage and the volume of air that the fan will circulate, running at the same speed in the summer season when the outside temperature is 70 deg. and that of the mine, as before, 60 deg. F.

(b) Assume the same conditions in the mine and the same respective temperatures and calculate the water gage and volume of air this fan will produce when running at the same speed and blowing instead of exhausting the air, for the winter and summer seasons, respectively.

Solution—(a) When the fan is exhausting, the fan shaft being the upcast, the effective depth of air column is D = 800 ft. The natural water gage due to this depth (barom., B. = 30 in.) is

$$\text{Winter,}\quad w.g._n = \frac{1.3273 \times 30\,(60 - 30)\,800}{(460 + 60)\,(460 + 30)\,5.2} = 0.72\ in.\ (positive)$$

$$\text{Summer,}\quad w.g._n = \frac{1.3273 \times 30\,(70 - 60)\,800}{(460 + 70)\,(460 + 60)\,5.2} = 0.22\ in.\ (negative)$$

In the circulation of 200,000 cu.ft. of air, under a 2-in. water gage, as stated in the question, therefore, the water gage due to the action of the fan is 2 — 0.72 = 1.28 in., the natural water gage, in this case, assisting circulation, being positive. In the summer season, the fan exhausting at the same speed as before will create the same ventilating pressure and water gage (1.28 in.); but, the natural air column now being negative (0.22 in.), the effective water gage producing circulation is 1.28 — 0.22 = 1.06 in. Then, since the circulation in any given mine or airway varies as the square root of the pressure or water gage, the quantity ratio is equal to the square root of the water-gage ratio.

$$\frac{x}{200{,}000} = \sqrt{\frac{1.06}{2}} = \sqrt{0.53} = 0.728$$

Summer (exhausting), $x = 200{,}000 \times 0.728 = 145{,}600$ *cu.ft. per* ***min.***

(b) When the fan is blowing the hoisting shaft is the upcast and the effective depth of air column is then D = 600 ft. The natural water gage is then 600/800 = ¾ of the value previously found; or ¾ × 0.72 = 0.54 in. (winter), and ¾ × 0.22 = 0.165 in. (summer). As before, the natural gage is positive in winter and negative in summer, which makes the effective gage 1.28 + 0.54 = 1.82 in. (winter) and 1.28 — 0.165 = 1.115 in. (summer). The circulation is then

$$\text{Winter (blowing),}\quad x = 200{,}000\sqrt{\frac{1.82}{2}} = say\ 190{,}800\ cu.ft.\ per\ min.$$

$$\text{Summer (blowing),}\quad x = 200{,}000\sqrt{\frac{1.115}{2}} = say\ 149{,}400\ cu.ft.\ per\ min.$$

The Coal Age Pocket Book

EXAMPLES FOR PRACTICE

1. How many feet of air column is equivalent to a mine water gage of three inches?

Solution—Under ordinary or normal conditions water weighs 815 times as heavy as the same volume of air; hence,

1 *ft.* (12 *in.*) *water column* = 815 *ft. air column*
1 *in. water gage* = 815 ÷ 12 = 68 *ft. air column*
3 *in. water gage* = 3 × 68 = 204 *ft. air column*

2. Express the pressure equivalent to 200 ft. of ordinary air column, in pounds per square ft.; ounces per square inch; inches of barometer; inches of water gage.

Solution—

200 ÷ 13 = 15.39 *lb. per sq.ft., nearly*
200 ÷ 117 = 1.71 *oz. per sq.in., nearly*
200 ÷ 920 = 0.22 *in. of mercury, nearly*
200 ÷ 68 = 2.94 *in. of water gage*

3. What is the pressure of the atmosphere, in pounds per square inch, corresponding to a barometric pressure of 30 in.?

Solution—

30 × 7.86 = 235.8 *oz. per sq.in.*
235.8 ÷ 16 = 14.74 *lb. per sq.in., nearly*

4. Find the pressure in ounces per square inch corresponding to a water gage of 2.5 in.

Solution—

2.5 × 0.58 = 1.45 *oz. per sq.in.*

5. Find the barometric pressure in inches of mercury corresponding to a water gage of 3.4 in.

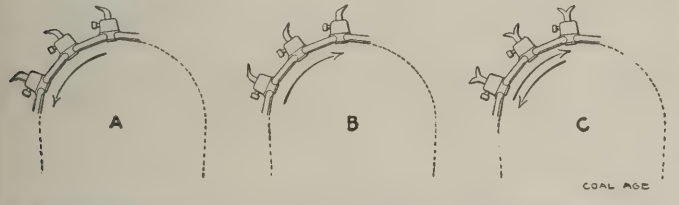
Solution—

3.4 ÷ 13.6 = 0.25 in.

6. If an aneroid barometer gives a reading of 29.65 in. on the surface, what should be the reading at the bottom of a downcast shaft 500 ft. deep where the ventilating pressure caused by a blowing fan gives a water gage of 2.85 in., assuming all readings are taken at about the same time?

Solution—The air column in this shaft will increase the barometric pressure 500 ÷ 920 = 0.54 in. The water gage due to the blower will still further increase the barometric pressure, at the foot of the downcast shaft, 2.85 ÷ 13.6 = 0.21 in. The reading of the aneroid, therefore, should be 29.65 + 0.54 + 0.21 = 30.4 in.

7. In a mine ventilated by an exhaust fan, giving a water gage of 2.33 in., if aneroid readings taken on the surface and at the bottom of the upcast shaft show a difference of 0.76 in., what is the calculated depth of the shaft?



Solution—The action of the exhaust fan makes the aneroid reading at the shaft bottom lower than it would be if the fan were not running, and decreases the difference of the surface and underground readings 2.33 ÷ 13.6 = 0.17 in. of mercury. The difference of reading due to the depth of the shaft only is, therefore, 0.76 + 0.17 = 0.94 in. of mercury. Reducing this barometric difference to air column gives for the approximate depth of the shaft 920 × 0.94 = say 865 ft. under ordinary conditions.

Inquiries of General Interest

Reversible Coal-Cutting Machine

I would like to draw attention to the reversible feature of the Sullivan "Ironclad" *C E-7*, shortwall machine. Those familiar with this machine know that it operates on the same principle as previous types of Sullivan continuous-cutting machines, for use in room-and-pillar work. The machine is sumped under the coal at one rib and undercuts the entire face of the room to the other rib where it is backed out and loaded for transportation to the next working place.

The new feature to which I refer, in the ironclad model, is its reversibility, which enables the machine to cut from right to left or from left to right. To do this, however, it is necessary to change the bits from the position shown in the sketch at *A*, to the position shown at *B*. The arrows show the direction in which the cutting

A Suggestion of a Double-Tooth Bit in a Reversible Coal-Cutting Machine

chain revolves, the first (*A*) cutting from right to left and the second (*B*) cutting from left to right. Of course, after changing the bits, the motor must also be reversed.

I want to make a suggestion, which, if possible or practicable, would greatly expedite the work, by enabling the machine to cut, either right to left or left to right, without the necessity of changing the bits. The suggestion is to use a double-toothed bit, as shown in the figure at *C*.

The scheme, if practicable, would possess another advantage, as it would then be possible, if a tooth was broken or dulled badly, to reverse it by loosening the set-screw and turning it over. I would like to have the views of readers of Coal Age who are familiar with this machine, in reference to this suggestion.

A Reader.

Oliphant Furnace, Penn.

Longwall Mining

I am much interested in the matter of longwall mining on the retreating plan, and would like to ask two questions:

1. Can any of the readers of Coal Age suggest a method of timbering or cribbing and the general arrangement of a longwall face over 300 ft. in length, when working a seam of semibituminous coal averaging 3½ ft. in thickness, under 300 ft. of cover. The roof is a hard slate, varying from 1 to 12 ft. in thickness; and overlying the slate is sandrock or a sandy shale, from 10 to 20 ft. thick. There are slips in the slate running almost at right angles to the face of the coal. What I most desire to know is the best method of arranging the timbering or cribbing to secure the proper breaking of the roof.

2. Is there a method of longwall retreating being worked successfully in either the Pittsburgh or Central Pennsylvania district; and, if so, where? I shall much appreciate any suggestions from readers who have had experience in this system of mining.

Bituminous.

Windber, Penn.

One of the most essential features in successful coal mining is a roof that will bend without breaking. The breaking of the roof over a longwall face almost invariably results in disaster. Success in the operation depends on maintaining a constant, traveling weight that advances with the progress of the work, only enough pressure being thrown on the face to break down the coal when it is undermined.

Cribs are only used in special cases of longwall mining. The more common method is to employ two and sometimes three rows of posts parallel to the face of the coal. These posts are set on a slight mound of dirt or slack that will enable them to take the pressure gradually without breaking and that will make it possible to draw them more easily, at the proper time. As the working face advances, a new row of posts is set in front and the posts at the rear are then drawn, so as to allow the roof to settle uniformly on the packs or waste.

In this connection, we would refer to the article by Samuel Dean, on Retreating Longwall Mining Methods, Coal Age, Vol. 4, p. 722; and the two interesting letters discussing this method, by Charles Waine and William James, Jan. 10, p. 99. We shall be glad to hear from readers in answer to the second question and to have further suggestions on this important subject.

Ventilation

Kindly answer the following question in Coal Age: What is the theoretical velocity of air corresponding to a 1-in. water gage? I am unable to recall the formula required for this calculation.

Forgotten.

Welch, W. Va.

The formula for finding the theoretical velocity of any fluid, air or water is $v = 8\sqrt{h}$.

Now, since 1 in. of water gage is equivalent to 68 ft. of air column, under normal conditions (Coal Age, Dec. 27, 1913, p. 990), we have, for the theoretical velocity of air (ft. per sec.), expressed in terms of water gage (in.),

$$v = 8\sqrt{68\ w.g.} = 66\sqrt{w.g.}$$

Therefore, for a 1-in. water gage, the theoretical velocity of air is $66\sqrt{1} = 66$ ft. per sec.

Examination Questions

Miscellaneous Questions

(*Answered by Request*)

Ques.—What method would you use in extracting pillars, using mining machines for this purpose, under ordinary conditions of roof and floor?

Ans.—Assuming a level seam and the conditions of roof and floor such as to enable mining machines to be used with safety in the extraction of pillars, two general systems are in use. Under suitable conditions of roof and floor, permitting the extraction of a considerable percentage of the coal in the first working, the rooms are often driven the usual width, say 20 or 24 ft., with pillars varying from 10 to 16 ft. wide, between them.

In that case, when the rooms have reached the limit the pillar is cut across at the end, by the machine, the cut being about 7 or 8 yd. wide. This being done, a stump is left that varies from 5 to 8 ft. wide, depending on roof and other conditions, and another cut, 7 or 8 yd. wide, is made across the pillar with the machine, as before. The coal is loaded out as each several cut is made, until the pillar is cut across. When this is done, the 5- or 8-ft. stump is removed with a pick and the roof allowed to fall. The same process is continued until the entire pillar is removed up to the entry stump.

Another method is adapted to roof conditions that are not as favorable to wide openings. In this case, the rooms are driven up as stalls 4 or 5 yd. wide, with pillars varying from 10 to 20 yd. in width, between them. Where the conditions will permit, wider pillars (100 yd.) are left and a face track is then laid along the face, the pillar having first been crosscut at its inby end. It is now worked out on the retreating plan.

In this method, two or three rows of posts are set parallel to the face of the pillar and at such a distance back as to permit the machine to be worked freely between the coal face and the first row of props. A cut is made with the machine across the entire face of the pillar. This coal is loaded out in the usual manner and a new row of posts set, after the track has been shifted forward a distance equal to the depth of the cut. The back row of posts is then drawn, after which another cut is made with the machine, as before. This process is continued until the entire pillar is removed, up to the entry stumps.

Ques.—(a) What percentage of fuel will be saved by heating the feed water of a boiler to 150 deg. F., by means of the exhaust steam, before introducing the water into the boiler, instead of feeding the water to the boiler at a temperature of 50 deg. F. Assume the total heat of vaporization or the heat above 32 deg. F., for a boiler pressure of 100 lb. per sq.in., as 1185 B.t.u. (b) Assuming that this percentage of fuel is saved, at a mine using 1200 lb. of coal per hr., what weight of coal will be saved in a day of 8 hr.?

Ans.— (a) The weight of coal burned being proportional to the heat (B.t.u.) developed, the percentage of fuel saved is the same as the percentage of B.t.u. saved in the heating of the feed water from 50 deg. to 150 deg. F. The heat thus saved is 150 — 50 = 100 B.t.u., per lb. of water evaporated, or steam generated. At a boiler pressure of 100 lb. per sq.in., the heat in the steam above 32 deg. F. being 1185 B.t.u., the heat above 50 deg. F. is 1185 + 32 — 50 = 1167 B.t.u. The percentage of heat saved is, therefore, 100 × 100 ÷ 1167 = 8.57 per cent. As previously stated, this is the percentage also of fuel saved by heating the feed water from 50 deg. to 150 deg. F., by means of the exhaust steam.

(b) The saving of fuel at a mine burning 1200 lb. of coal per day is, therefore, 0.0857 (8 × 1200) = 822+ lb.

Ques.—What would be the height of motive column in a mine where the depth of both the upcast and downcast shaft is 300 ft., the temperature of the downcast shaft being 32 deg., and that of the upcast, 48 deg. F.?

Ans.—Assuming a level surface, or what is the same, a level seam, the motive column, in this case, depends on two temperatures only; namely, those of the upcast and downcast shafts, respectively. The motive column may be calculated in terms of the downcast air, as follows:

$$M_d = \frac{(T - t)\ D}{460 + T} = \frac{(48 - 32)\ 300}{460 + 48} = \frac{4800}{508} = 9.45\ ft.$$

In terms of the upcast air, this air being lighter than that of the downcast, the column will be longer. The calculation is as follows:

$$M_u = \frac{(T - t)\ D}{460 + t} = \frac{(48 - 32)\ 300}{460 + 32} = \frac{4800}{492} = 9.75\ ft.$$

Ques.—What pressure will be necessary to pass 20,000 cu.ft. of air per min. through an airway 6x14 ft. and 3000 ft. long? Assuming there is no change in the temperature of the air current and ignoring any change in volume due to a decrease of ventilating pressure, if the volume of the return air is found to be 20,300 cu.ft., what percentage of gas is contained in this current; and, assuming that the gas present is all marsh gas, what indication would be shown on the flame of the safety lamp in the return current?

Ans.—Under the assumed conditions, the increase in volume, which is 20,300 — 20,000 = 300 cu.ft. per min., represents the volume of gas in the return current. The percentage of gas present is then $\frac{300 \times 100}{20{,}300} = 1.47$ per cent. It would not be possible to detect this percentage of gas on the flame of an ordinary Davy lamp.

Corrections

(*Examination Question, Dec. 13, 1913, p. 914*)

Ques.—If 20,000 cu.ft. of air and gas, etc.

Ans.—The answer should read as follows:

24,600 + 1892 — 20,000 = 6492 *cu.ft. per min.*

(*Examination Question, Jan. 10, p. 103*)

Ques.—We have a tank full of water, etc.

Ans.—The answer should read as follows:

2394 ÷ 672 = 3.56 *hours, say 3 hours 30 min.*

Coal and Coke News

Washington, D. C.

There seems every reason to expect an elaborate inquiry will be made into both the Colorado and Michigan mining strikes by the House Committee on Mines. It is believed that the hearings on the subject will begin within a couple of weeks and that an effort will be made to thresh out all of the facts in both situations just as was done with reference to the West Virginia mine strike situation.

Sharp criticism of this plan is being offered by a number of congressmen who are of the opinion that the controversies in question do not involve any subject over which the United States Government has jurisdiction. Insofar as the Government has anything to do in the matter, it is claimed by them, the subject is one for investigation by the Department of Labor which is under the law specifically vested with powers of mediation and conciliation whenever it can induce employers to accept its offices in that capacity.

Some time ago an attempt was made to induce the new industrial relations commission to look into both of these strikes and it was semi-officially announced that the commission had been brought to the point of accepting this work as one of its duties.

Later on the decision was reached not to take up the investigation of contemporary labor controversies, and while the rule thus established was broken in the case of the New York garment-workers strike, this apparently was only a temporary lapse from the position then taken, inasmuch as it has now been practically resolved by the mines committee to take up this work, thus indicating that the effort to shoulder it off upon the industrial commission was not successful.

HARRISBURG, PENN.

The constitutionality of the 1913 act providing for a tax on anthracite coal was attacked in the Dauphin County Courts on Jan. 22, when a suit in equity was filed by the People's Coal Co., of Scranton. Frederic W. Gleitz, counsel for the company and an ex-Attorney General, filed the proceedings, which are directed against Auditor General Powell and State Treasurer Young, fiscal officers of the state. The Attorney General's department accepted service.

The act signed June 27, last, provides for a 2½ per cent. tax on coal mined, and the money thus raised is to be divided equally between the state and the municipalities of the county where the coal is mined.

It is set forth by the papers filed that the constitution is violated because the tax is confiscatory, and that the coal companies would not be doing their duty to their stockholders or the public if the act were not tested. An injunction asking that the Auditor General and State Treasurer be restrained from assessing, collecting or distributing the tax is sought.

The People's Coal Co. asserts that the tax it must pay will amount to $15,000 annually and that the total tax will reach in the state over $7,000,000.

The chief contention will be that the measure is class legislation and that it is in conflict with the 14th amendment of the constitution of the United States, and is also in violation of the constitution of the state.

If the tax is to be laid, then, all coal should be included and not only anthracite. It is also contended that the bill in effect is not a revenue-producing act, but levies a personal tax. The method of distributing the tax is also unconstitutional, it is contended, upon the ground that the money would be distributed among municipalities by means of special appropriations.

A great many people believe the strongest point against the law is its alleged conflict with the clause of the United States constitution forbidding any state to levy export duties, that being the exclusive privilege of congress. A considerable quantity of anthracite is exported to Canada, and it is said it would be impossible to differentiate on the product mined for that country and that intended only for home consumption. The test of the validity of the law will be carried to the United States Courts as well as those of Pennsylvania.

Filing of the action in equity will not halt the steps taken by the Auditor General for the collection of the tax, because the bill entered in the case does not ask for an injunction, except after the hearing. Operators have until the end of January to file their sworn statements of production during 1913, and then bills will be sent out from the capitol.

Attorney-General Bell will determine during the week the manner of meeting the suit, whether a demurrer or an answer should be filed. It is probable that the suit will be argued in Harrisburg before the Dauphin County Court within a few months, and that other coal companies will enter into the proceedings in order to test questions that have arisen.

PENNSYLVANIA

Anthracite

Scranton—The legal suit against the Peoples Coal Co. by the Lackawanna Coal Co. begun as an injunction proceeding to restrain the former firm from mining coal out of its bounds in West Scranton has been terminated by the Peoples Coal Co. purchasing the land in dispute.

Hazleton—The building of five new mess houses at as many collieries has been authorized by the officials of the Lehigh Valley Coal Co. These structures will be of a standard design based on that of the mess house built experimentally at the Prospect Colliery of this company. The size will, however, depend upon the number of men working at the various operations. Their construction will be started at once.

Wilkes-Barre—Judge Garman, of Luzerne County recently granted a compulsory non suit in the case of Cornelius Vistock against the Pennsylvania Coal Co. Holding that the mine foreman and not the coal company or mine superintendent was responsible for the safety of mine passages after they were opened. The Supreme Court in a somewhat similar decision holds that neither a superintendent nor the owners of the colliery are at liberty to disobey the mine foreman's instructions as to how business inside the mine shall be conducted and managed.

Plymouth—The grievances of the miners employed at the No. 11 Colliery of the Lehigh & Wilkes-Barre Coal Co. regarding the reinstatement of check docking boss Joseph Bogdan has been decided in favor of the miners, and the checking boss is back at work. The contentions of the officials was that the presence of Bogdan at the colliery created trouble and finally resulted in a strike. The difficulty was brought to a temporary settlement by the appointment of District Vice-President Joseph Yanis as check docking boss.

Bituminous

Johnstown—Extensive changes are expected to be made shortly in the Kennerly coal holdings in this vicinity. Philadelphia banking houses are said to be interested both in the property of the Valley Smokeless Coal Co. and the Seward operations of Mr. Kennerly. It is said that one firm is interested to the extent of $100,000 and another for about $250,000 which indicates that the bankers now control the property.

Furnace Run—The general repair shops of the Allegheny River Mining Co. at this place were recently placed in operation. Repair work for all of the mines of the above mentioned company in Jefferson and Armstrong counties will be done at these shops.

Rockwood—Hitchman Bros. are making preparations for the opening of their big coal tract about 4 miles west of Rockwood, comprising approximately 5000 acres of coal. It is said that two openings will be operated and that construction work will be begun in the near future.

Du Bois—The strike which has been in progress for some time at the Eriton shaft has been ended, a satisfactory understanding, which is to be in force until the present wage-scale agreement expires, having been arrived at.

Washington—The entire town of Desco, together with a modern coal and coke plant recently became the property of I. W. Semans, of Uniontown. This town, which has just been completed, comprises 57 houses, 257 coke ovens, and 300 acres of coal land together with an uptodate mine.

Wampum—I. E. Ingham & Co. will shortly open a new coal mine at this place. It is expected that about 65 more men will be employed.

WEST VIRGINIA

Charleston—A $60,000 coal tipple of the Boomer Coal & Coke Co. was completely destroyed by fire recently. It was necessary to use dynamite to blow up this structure in order to save three smaller ones which were in close proximity. The cause of the fire was unknown.

Attorneys E. W. Keatley and C. M. Alderson recently returning from New York where they conferred with the English and American representative of the British syndicate which contemplates the purchase of the entire New River coal fields state that there is every prospect of a consummation of the deal.

Clarksburg—The entire holdings in the Irvington-Late Coal Co. have been purchased by Gordon D. Late, who will continue the operation of the plant under the name of the Gordon D. Late Coal Co.

The organization of the First Aid to the Injured Association, which was to have been effected at Fairmont, Jan. 22, was postponed indefinitely on account of there not being enough of the coal operators present to express their sentiment regarding the matter. Such associations have been formed in a number of states, and many of the coal operators throughout West Virginia are desirous of forming a like organization here.

Fairmont—Fire recently destroyed the tipple of mine No. 21 of the Consolidation Coal Co. at Gypsy. The origin of the conflagration is unknown. The construction of a temporary tipple was at once begun and it was stated that no men would lose time on account of the fire.

TENNESSEE

Chattanooga—The Continental Coal Corporation has sold approximately 3000 acres of its undeveloped lands in Bell County, Kentucky, for about $550,000. This transaction means a reduction of something like $700,000 in the company's bonded indebtedness and about $100,000 in its floating loans.

KENTUCKY

Madisonville—Rumors continue to circulate in the western Kentucky district, to the effect that deals are pending for the transfer of coal rights in that section, in addition to those already reported as consummated. Options are said to have been given on large properties to the same interests which have made the purchases heretofore noted. These reports, however, continue to limit themselves to undeveloped property, and no options or sales have yet been suggested relating to existing operations.

Pineville—Reports are to the effect that contracts have been let for the camp construction and development work on four large coal operations in the Harlan county field, which, when finished, will add about 2000 tons a day to the production of the field. This is already estimated to be about 6000 tons a day. Other developments are projected in that field, following various deals which have been reported within the past few months.

OHIO

Columbus—A joint committee of operators and miners will assist the newly created safety commissioner John M. Roan to prepare regulations to reduce the hazard in mines. A meeting of mine bosses and superintendents of the Hocking Valley field, held at Athens, has promised to give the movement enthusiastic support. The plan is to have all regulations promoting safety passed upon by both miners and operators, so that there will be no friction in introducing reforms.

Bellaire—The property of the Gordon Coal Co., of Stewartsville has been leased to J. F. Johnson, of this city, who has also secured a 14-months' option on the property which consists of one coal mine and all the necessary equipment. It is expected that the output of this mine will be approximately doubled in the near future and the number of men employed greatly increased.

INDIANA

Terre Haute—Nine miners were injured, Jan. 27, one probably fatally, when the engineer at Mine No. 1 of the New Central Coal Co. lost control of his engine, causing the cage carrying the men to run wild to the bottom of the pit, a distance of 200 ft., where all were hurled out. The injured men were brought to this city.

Indianapolis—The convention of Michigan, Ohio and Indiana Coal Dealers will be held in this city this year, the directors having accepted an invitation extended by the Indianapolis Retail Coal Merchants Credit Association. It is expected the date will be about June 15. H. H. Deam, Bluffton, Ind., is president of the association and B. F. Nigh, Columbus, Ohio, is secretary.

ILLINOIS

Duquoin—Abe Eaton, manager of the Majestic mine, has been acquitted at Mt. Vernon on the charge of murdering Wm. Sisney, president of the miners' union here. The case was taken to Mt. Vernon on change of venue. The trouble arose over an argument several months ago.

Danville—An idea as to what business conditions in Illinois have been during the year 1913, may be gained from the fact that the Federal Court of the Eastern District of Illinois, shows that there were 177 bankrupts in the southern part of Illinois during the year. The number in 1912 was 110. For years previous to 1912 the number was far below 100. Included in the number for 1912 and 1913 were several big coal companies.

Pana—Owing to the mild weather and slight demand for coal nearly a score of the largest coal mines in the central Illinois district have recently suspended operations. These suspensions have thrown more than 3000 men out of employment.

Chicago—The Chicago, Rock Island & Pacific R.R. Co. has stored about 500,000 tons of coal at Des Moines and West Liberty, Iowa. This has been done on account of the threatened general strike of the miners in the Middle West on Apr. 1.

KANSAS

Topeka—Based on the number of men used in the mines 30% more coal was produced at the State Penitentiary during 1913 than in 1912. Five months' daily reports show 33,323 working days in the mines in 1912 as compared with 27,858 working days in the same period of 1913. Last year the men from the mines were worked in the construction of the prison twine plant and buildings destroyed by the fire in April. At the present time only about 175 men are used in the mines as compared with 250 a year ago.

SOUTH DAKOTA

Woonsocket—Excitement has been caused here by the discovery of a bed of lignite coal on the farm of Joseph Dodd

WYOMING

Cumberland—A diamond drill operated by representatives of the Union Pacific Coal Co. has located a vein of coal 18 ft. thick, seven miles south of Cumberland in Uinta County.

Smoke Consuming Mechanism. D. D. Keltner, Des Moines, Iowa. 1,078,927, Nov. 18, 1913. Filed Oct. 14, 1912. Serial No. 725,561.

Mine Car Lubricator. J. H. Thomas, Independence, Col. 1,080,500 Dec. 2, 1913. Filed May 29, 1913. Serial No. 770,716.

Gas Producer. C. M. Garland, Assignor to Camden Iron Works, Camden, N. J. 1,079,234, Nov. 18, 1913. Filed Jan. 6, 1913. Serial No. 740,469.

Self Acting Conveyor for Coal and Goaf-Packing in Colliery Inclines of Low Gradient. L. Hyve, Dorignies, France. 1,079,176, Nov. 18, 1913. Filed Oct. 15, 1912. Serial No. 725,851.

PERSONALS

E. T. Hendon, receiver for the Oak Leaf Coal Co., a bankrupt concern of Cordova, Alabama, was recently elected trustee without opposition at a meeting of the creditors.

J. J. Malloy for the past 7 years a mine foreman at Davidson, Penn., has been appointed superintendent of the Filbert plant of the H. C. Frick Coke Co. He will assume his new duties on Feb. 1.

H. H. Robertson, president of the Asbestos Protected Metal Co. of Beaver Falls, Penn., has been elected vice-president of the Pittsburgh Branch of the National Council for Industrial Safety.

L. O. Mellinger, superintendent of the Furnace Run operations of the Allegheny River Mining Co., has resigned to accept service with the Rochester & Pittsburgh Coal & Iron Co. He will be succeeded Feb. 1 by Samuel Wallwork.

L. C. Sherrill, prominently identified for the past few years with the Pioneer Coal & Coke Co., of St. Louis, has resigned that company to accept the sales management of the fuel department of the Roman & Bush Pig Iron & Coke Co.

Ralph Lockhard formerly superintendent of the Quemahoning Coal Co.'s mines at Ralphton, Penn., has been elected manager of the Canadian Collieries, Ltd., which has developments under way in the vicinity of Cumberland, B. C.

Thomas Davis, of Nanticoke, has been elected a member of the executive board of the United Mine Workers of America by the members of the union in that district, to fill the vacancy caused by the death of John Fallon, of Wilkes-Barre.

Heber Denman has been appointed asst. general manager under Thos. Fisher, of the Berwind-White Coal Mining Co. at Windber, Penn. This company recently abolished the office of general superintendent formerly held by Walter R. Calverley.

At the recent annual meeting of the St. Louis & O'Fallon Coal Co., T. M. Jenkins, former general manager of the St. Louis & Suburban Ry., was elected president; Adolphus Busch, Third, vice-president; Geo. Kauffman, secretary and treasurer.

William A. Rodda, of the United Mine Workers of America, was held up on the night of Jan. 19, by two men on the limited train of the Baltimore & Ohio R.R. and robbed of the membership rolls of the newly organized lodge of the United Mine Workers in Frostburg, Md.

Daniel F. Connor, general sales agent of Whitney & Kemmerer, returned recently from a trip looking over the conditions throughout the territory. He was very optimistic over the outlook of the industry and was gratified at the progress which has been made during the winter. He expects to sail for Panama, Feb. 7.

A. Reiche formerly general manager of the Orenstein-Arthur Koppel Co. at Koppel, Penn., has severed his connection with the firm to assume the position as managing director of a German concern manufacturing locomobiles and agricultural machinery. He will be succeeded by Mr. Erich Joseph formerly of New York.

Edgar Wallace, editor of the United Mine Workers Journal, has given bond in the Federal Court in Indianapolis for his appearance in Colorado to answer an indictment of officials of the union charging them with violation of the Sherman anti-trust law in restraining trade in coal and boycotting mines not employing union labor. Other officials were also indicted.

John R. Bryden, for many years the general manager of the Scranton Coal Co. and the Elk Hill Coal Co., has tendered his resignation, and has been succeeded by Wiliam L. Allen, formerly general superintendent of the two companies. In addition to having been the general manager, Mr. Bryden was a member of the board of directors, and also vice-president. It is not known whether or not he is to retire from these positions as well.

OBITUARY

D. D. Shumway, vice-president and treasurer of the Springfield Coal Mining Co., a prominent coal man of the state of Illinois, suffered a stroke of appoplexy at 5 o'clock, Jan. 20, and died at St. Johns' Hospital a few hours later. The coal company of which Mr. Shumway was an officer, recently suspended operations at all of its mines for an indefinite period and it is thought that the failure of the company to show a profit is partly responsible for the death of the vice-president and treasurer. Mr. Shumway is survived by his widow, three sons, one brother and two sisters.

CONSTRUCTION NEWS

Furnace Run, Penn.—An additional 500-kw. Westinghouse turbo generator is being installed by the Allegheny River Mining Co. at this place.

Hartford, Ark.—The Central Coal & Coke Co. announces that it will shortly spend between $150,000 and $200,000 in opening a new coal mine near this place.

Salem, Ohio—The Dunn Coal Co., of this city, which has under lease a large area of coal north and east of Beloit, is preparing to open mines early in the spring.

Superior, Wis.—The mammoth coal dock of the Berwind Fuel Co. will be completed this year. It is also contemplated to build a briquette plant during the coming season.

Somerset, Penn.—The Consolidation Coal Co. is rushing work on its openings on the John Biesecker farm in the Jenner field. A number of new mines will shortly be opened.

Kittanning, Penn.—A 750-kw. alternating current generator direct connected to a Ridgway engine is being installed at the Conifer operations of the Allegheny River Mining Co.

Columbus, Ohio—An order for 1000 coal cars has been placed by the Kanawha & Michigan Ry. with a Columbus car manufacturing company. The Hocking Valley Ry. has also contracted for 1000 cars with an eastern concern.

Louisville, Ky.—The Harlan Coal Mining Co. has awarded a contract to the Roberts & Schafer Co. for a new "Marcus" coal tipple and retarding conveyor. This plant will be built at Coxton, Ky. at an approximate cost of $25,000.

Tacoma, Va.—The Greenough Mining Co. will increase its plant by opening five new mines in close proximity, largely increasing the output. The company a few days ago increased its capital stock from $50,000 to $1,000,000.

Jenkins, Ky.—The Consolidation Coal Co. makes the announcement that it will open a number of new mines, starting work about Feb. 1. This will greatly increase the coal tonnage from the works in the Kentucky coal field.

Charleston, W. Va.—The Roberts & Schafer Co. of Chicago has secured a contract from the Paint Creek Collieries Co. for the building of a new mining plant in which the "Marcus" table screen will be installed. This tipple will be built at Olcott, W. Va., at an approximate cost of $27,000.

Viper, Ky.—The Lexington & Eastern Railroad Co. is completing plans for the construction of an 8-mile branch up Mace's Creek from Viper to reach rich coal and timber land holdings of a number of corporations, one of them the Kentucky River Harwood Co. having a number of large mills.

Pound, Va.—The Indian Creek & Pound River R.R. will start immediately the construction of the Upper Pound River branch of the road to reach extensive coal and timber fields soon to be developed by the Guest River Coal Co. and the Tidewater Lumber Co. The development will total several hundred thousand dollars.

Athol, Ky.—The Louisville & Nashville Railroad Co. building a 20-mile cut-off between Athol and Beattyville Junction in order to reduce curves and heavy grades has begun laying steel on the new line. It is expected, that this work will be completed and in operation within 60 days. The company is spending about $2,000,000 in the work.

Whitesburg, Ky.—It is announced here by representatives of the Mineral Development Co. that a big development work will be started by this company Mar. 1 at Lower Boone's Fork above here where at least two good-sized industrial cities will be built and a large number of mines opened. Several million dollars will be expended in the development.

Fleming, Ky.—S. T. Mundy who has the contract for the construction of the three-mile branch road up Yount's Fork—a spur of the Lexington & Eastern—has just put 400 extra men on the work in an effort to push its construction. The road will be completed and in operation within 60 days. The Mineral Fuel Co. will spend several million dollars in developments on Yount's Fork.

Waynesburg, Penn.—Rumors are circulating in Greene County to the effect that the Baltimore & Ohio R.R. is planning an east and west line through Greene County, which would open up rich coal territory. It is anticipated that this line would pass through Waynesburg, Rogersville, Rutan and Graysville emerging through the southern section of West Finley Township, Washington County, where but a short line would connect it with the Pittsburgh & Wheeling division of the Baltimore & Ohio.

Whitesburgh, Ky.—A number of large coal developments have been recently started in the eastern Kentucky field especially along the Lexington & Eastern R.R. Among these might be mentioned the Wolf Valley Coal & Coke Co., which proposes starting development work in the next few days and having everything in readiness to ship coal by spring. The Garret-Hardwick Coal Co., has also made the necessary arrangements to start immediately the work of development. A modernly equipped mining plant will be built as well as a number of large sawmills. The Williamson & Pond Creek R.R. Co. also contemplates building 17 miles of coal and

lumber road from the head waters of Pond Creek, to a connection with the Chesapeake & Ohio R.R.

Whitesburg, Ky.—The present year will see an unusual amount of railroad building throughout the Big Sandy and Kentucky River valleys, which comprise a large portion of the coal fields of eastern Kentucky. The Kentucky River and Tug Fork R.R. Co. was recently organized to build a line 17 miles long from the head waters of Pond Creek connecting at Shelby Station, with the main line of the Chesapeake & Ohio up to Big Sandy, also the Baltimore & Ohio branch reaching the Consolidation Coal Co.'s extensive operations at Jenkins. A branch line of the Baltimore & Ohio at Long Ford near the Letcher-Pike border, a distance of 8 miles, has also been announced. This is to reach the holdings of the Elkhorn Gas & Coal Mining Co. A large number of branches of the Lexington & Eastern are assured in Letcher and Perry Counties. These include the Pottersfork, Younts Fork and Bottom Branch extensions to reach the holdings of the Mineral Fuel Co. Branches of the Lexington & Eastern are also planned up Big Leatherwood, Line Fork, Mace's Creek and Rockhouse Creek. It is expected that all of these will be built during the present year.

NEW INCORPORATIONS

Linton, Ind.—The Linton-Summit Coal Co. has increased its capital stock from $45,000 to $50,000.

Danville, Ill.—The Beach Flats Coal Co. has increased its capital stock from $100,000 to $125,000.

Danville, Ill.—The Two Rivers Coal Co. has increased its capital stock from $100,000 to $125,000.

Strattanville, Penn.—The Co-operative Coal Co. has been incorporated with an authorized capital of $50,000.

Cincinnati, Ohio—The Beddall Coal Co., of Union County, has changed its name to the Hercules Coal Co.

Lexington, Ky.—The Eureka Coal & Mineral Co. has been incorporated with a capital stock of $75,000 to develop coal lands.

Salem, Ohio—The Salem Mining Co. has filed papers with the secretary of state increasing its capital stock from $75,000 to $150,000.

Barbourville, Ohio—The Tye-Wheeler Coal Co. has been incorporated with a capital stock of $10,000. The incorporators are George W. Tye, R. R. Wheeler and Myrtle Tye.

Nashville, Tenn.—The Tennessee River, Coal & Coke Co., of Hamilton County, has been organized with a capital stock of $125,000. The incorporators are J. P. Gillespie, F. T. Tarver, J. T. Walker, J. E. Pride and G. D. Murray.

Wetumka, Okla.—The Hokesy Mining & Development Co. has been organized with a capital of $6000. The incorporators are Thos. H. Dunson, Laura E. Dunson and F. H. Williams, all of Wetumka.

Columbus, Ohio—The Bixler-Ohio Coal Co. has been organized in Columbus to mine and deal in coal. The capitalization is $20,000 and the incorporators are R. T. Irwin, J. W. Miller, A. Roahrig, R. M. Stimmel and D. R. Postlewaite.

Uniontown, Penn.—The Biddle Coal & Coke Co. has been organized in Uniontown to mine coal and manufacture coke. The capital stock is $250,000, and the incorporators are A. P. Austin, J. P. Robinson, John B. Carr, John E. Hess and George Patterson, all of Uniontown.

INDUSTRIAL NEWS

Cincinnati, Ohio—Fire believed to be of incendiary origin recently totally destroyed the coal elevator of the Baltimore & Ohio Southwestern R.R. in Cincinnati entailing a loss estimated at $10,000.

Waynesburg, Penn.—George E. Rice, of Waynesburg, recently closed a deal for several small tracts of coal in Belmont County. This purchase gives Judge Steel and his associates title to about 8000 acres of coal on the Baltimore & Ohio R.R.

Charleston, W. Va.—The Safe Deposit & Trust Co., of Pittsburgh, Penn., has purchased from Edward E. Duff, trustee, 14,386 acres of land in Kanawha and Boone Counties, formerly owned by the Forks Coal Co. The price was reported as being $124,000.

Cairnbrook, Penn.—Noah Blough, owning about 100 acres of coal land above Shade Furnace, closed a deal with H. C. Cook, of Johnstown, for the purchase of the tract for $25,000. This sale means another opening along the Cairnbrook extension of the South Fourk branch.

Fairmont, W. Va.—A report was recently circulated that negotiations were under way which looked to the merging of the Elkhorn Fuel Co. with the Consolidation Coal Co. The properties of these two firms in Kentucky are contiguous and if the deal is effected, it will bring under one management over 400,000 acres of coal in Kentucky.

Philadelphia, Penn.—Figures for the first 11 months of 1913 show that the Reading R.R. shipped more soft coal than hard. Of the total shipments of 27,609,127 tons of coal handled during the first 11 months 15,761,638 tons were bituminous coal and 11,847,489 were anthracite. In other words 57 per cent. of the total coal shipments over the road were of bituminous.

Wheeling, W. Va.—During the past week or so the coal industry in West Virginia has revived considerably, and the mines are now working smoothly and steadily while the demand for coal has increased. The uneasiness over the conference between the miners and operators which will take place in April is thought to be partly responsible for the increased purchasing of coal.

Columbus, Ohio—Requests have been made of Attorney-General Hogan that he drop the suits started by the state against the Columbus & Ohio, Hocking Valley and the Kanawha & Michigan railways to dissolve joint ownership between the three lines. It is said by the officials of the railway companies that the federal decision dissolved the relationship and that this has been lived up to.

New Orleans, La.—The Alabama & New Orleans Transportation Co. recently launched the largest lighter ever built in the South. This craft, which is to be propelled by internal combustion engines has a carrying capacity of 1000 tons, is 240 ft. long and has a rate of coaling vessels of 275 tons per hour. The vessel will be a valuable acquisition to the large fleet of steel barges now owned and operated by the company.

Elkhorn, Ky.—The Elkhorn Fuel Co. which recently purchased a large area of fine coal land from the Long Fork Coal Co. on Long Fork Creek, Pike County, makes the announcement that it will begin immediately the initial work of development there. A first-class coal mining plant will result. The company is well under way on a mammoth coal mining plant on Beaver Creek, building two industrial cities Wayland and Allen.

Indianapolis, Ind.—Resolutions sent in to the national convention of the United Mine Workers of America from various parts of the central competitive field indicate that it is probable that the scale committee's demands will include one for a 10% advance in wages, and that probably the Ohio miners demand for "run-of-mine" will be broadened out to include the remainder of the central competitive field. These demands will be laid before the operators at Philadelphia Feb. 3.

Fayetteville, W. Va.—It is rumored in mining circles that the Virginian R.R. will soon award six leases in and around Mullens. It is stated that several applicants for the leases were in the field, but probably two large mining syndicates will be awarded all six. The territory embraced in the field is understood to be 5000 acres, which the road recently acquired in exchange for land situated on Cabin Creek. The whole territory is located on the main line of the Virginian.

Pittsburgh, Penn.—More than 1,000,000 bushels of coal were shipped down the Ohio River, Jan. 22, towed by boats operated by engineers, who, according to the Marine Engineers Association, are strike breakers. The Monongahela River Consolidated Coal & Coke Co. and the Diamond Coal Co., the heaviest shippers on the river, are holding out against the union engineers who on Jan. 1 demanded an increase in salary from $100 a month and board to $125 a month and board.

Birmingham, Ala.—Chief Mine Inspector Nesbitt has announced the successful candidates for state mining certificates for the first- and second-class mine foreman and fire bosses in the examinations held Jan. 20 to 22. In the first class foreman's list William Drury took first place with an average of 91. William Chase and William Mulholland taking second and third places. Among the first class fire bosses J. Y. Malone and Edgar McElreath tied for first place. U. West made the highest mark for second-class mine foreman. The percentage of failures was comparatively low. Many of those who would have applied for certificates were not allowed to do so because they had not had actual experience with safety lamps in the mines. Without this knowledge, other qualifications are of no avail.

Coal Trade Reviews

General Review

Slowing down in operations and lower prices characterize the anthracite market; consumers have full supplies and demand light. January bituminous trade considered the worst in years. Accumulations the rule and much coal on demurrage. Producers have lost their former confidence and even strike scare fails to stimulate business.

The stimulating effect of the recent cold snap has died out, and the anthracite trade has again relapsed into its former lethargy. The heavy production and light consumption, due to the unseasonable weather, has resulted in such large accumulations that operators are being forced to restrict production for the second time this year—a most unusual procedure in the mid-winter season. The dealers are filled up on all sizes with the possible exception of some of the steam grades; there is only a scattering demand, and orders are promptly filled. The independents are endeavoring to force the market with substantial concessions, particularly on egg coal.

The bituminous market is under equally heavy pressure. Accumulation at all points is the rule, and the spot market is much depressed with substantial concessions on the regular circulars being freely offered. The January trade is considered by some as the worst for that month, in the history of the industry. Even under heavily curtailed operations, the producers are experiencing much difficulty in placing their tonnage. As a rule, the movement on contracts continues fair, but some suspensions have even been noted in this business. Consignment coal is appearing in all parts of the country, which is tending to make buyers cautious.

The Pittsburgh district reports little inquiry with prices still being cut, and operations reduced to 50% of full rated capacity. The opinion prevails among many that there will be a suspension of some duration beginning April, which will be followed by a short but active and profitable summer trade. The new January circular in Ohio has been fairly well maintained, but the consistently warm weather has severely shaken the confidence of the sellers. The possibility of a suspension in mining Apr. 1 is doing little to stimulate the market, a great many manufacturers, working under restricted operations, finding it possible to accumulate stocks on their regular requisitions.

The accumulations at Hampton Roads last week were the highest for some months, while the demand from all sources was particularly light, although prices continue holding moderately firm with some agencies even short of tonnage for immediate loading. The demand in the Southern markets continued far below the average for this period, some inquiries on contracts being the only favorable feature in that market.

Although there has been an occasional cold snap in the Middlewest, the more or less continued mild weather has produced almost summer-like conditions in the coal trade. Prices have reacted to new low levels, and even the strike scare has failed to help matters. Quotations on contracts are holding moderately steady, but there is considerable shading on spot business. It is stated that the operators will go into convention with the miners, with instructions to effect a settlement at any cost. There is also a strong movement to continue operations pending a settlement so that consumers feel relatively safe.

EASTERN MARKET

BOSTON, MASS.

Active campaigning for contracts already begun on Hampton Roads coals but buyers are expected to be slow responding. Low spot prices have unfavorable effect. Stocks large everywhere. Anthracite inquiry confined to odd sizes and buyers are conservative.

Bituminous—Preliminary canvassing for contract business on the part of some of the Pocahontas and New River agencies is causing considerable comment. Buyers especially are beginning to feel this will be an "easy" year and they are not much inclined to close business until they can get a better line on spring developments. Practically all the Southern shippers are expected to make an aggressive campaign for contracts but it is probable that the season will be slow starting and further that it will spread over longer than usual.

Meanwhile the accumulations at the Virginia piers are still very much in excess of current requirements and this in spite of rigid curtailment at most of the operations. The spot market is considerably depressed and reputable coals have been offered more or less freely at a considerable discount from the $2.85 basis. Further offerings of "market coal" for delivery inland have had an unfavorable effect on the market as a whole and particularly those buyers who might otherwise be disposed to come in early. Government and off-shore requisitions are few in number and even the large corporations are backward about accepting their full monthly quotas on contract. Outside of these factors that are pressed with coal to move there is, however, almost nothing doing on Pocahontas and New River in this territory at this writing.

Georges Creek shares the general apathy, and shipments are extremely light for the season. The demand for the higher grade Pennsylvania is still very quiet, with no significant change to report. Stocks are large in every direction.

Anthracite—There is only scattering demand, and that for odd sizes to piece out the next month or so. Few dealers have courage to buy further ahead as February weather is uncertain. The slow movement of barges is inducing some to be more forehanded, but there is almost no life to the trade.

Water Freights are somewhat firmer on account of the storms that have prevailed; 75c. is now the minimum rate for steam or barge tonnage from Hampton Roads to Boston, but inquiry is confined to a few large shippers.

Current wholesale quotations are about as follows:

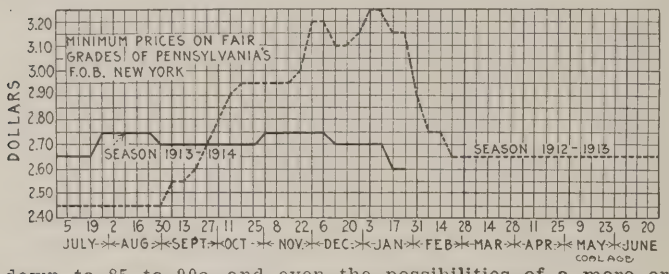
	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.95@1.55	$1.25@1.60	$1.67@1.77	
Philadelphia*	2.20@2.80	2.50@2.85	2.92@3.02	
New York*	2.50@3.10	2.80@3.15	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.80@2.85
Boston†				3.50@3.67
Providence†				3.58@3.72

*F.o.b. †On cars.

NEW YORK

Full stocks of anthracite, both at tidewater and all-rail. Operations heavily curtailed and individual prices on domestic grades decline sharply. Bituminous also at a low ebb. Much consignment coal reported and practically no spot business being negotiated.

Anthracite—The New York hard-coal trade is unchanged but slower if anything. As is to be expected in a weather market, such as now prevails, the dullness is accentuated on the domestic sizes. These are all in poor demand, the trade being full up both all-rail and at tidewater. Egg coal is probably the heaviest and if the unseasonable weather continues, and there is no curtailment in mining, there will be considerable stocks of this grade carried over. Stove coal is not in such excess supply.



Curtailment in mining has become generally established throughout the region. Nearly all the large companies are restricting operations to a greater or less extent while individuals are said to be down to a basis of about three days per week. Since the consumption of the steam sizes is not affected so much by the unsatisfactory weather conditions, there is somewhat of a shortage of these due to the curtailed operations. Rice, barley and No. 2 buckwheat are particularly short, but all the finer grades are in rather active demand as the output of these is much reduced by freezing weather.

We quote the New York market considerably off from last week, as follows:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.00	$4.50@5.00	$5.05	$4.45@4.95
Egg	5.25	5.25	5.30	5.20
Stove	5.25	5.25	5.30	5.15@5.20
Chestnut	5.50	5.50	5.55	5.35@5.45
Pea	3.50	3.55	3.50	3.45
Buckwheat	2.75	2.75	2.70@3.45	2.25@2.70
Rice	2.25	2.25@2.35	1.95@2.20	1.90@2.20
Barley	1.75	1.75@1.80	1.70	1.50@1.70

Bituminous—The soft-coal situation is even worse than anthracite. Nearly everyone seems to be stocked up to the limit and quite a little demurrage coal is being reported. Operations in Pennsylvania are about 75% capacity and business is confined mostly to contracts, requisitions on which are fair. Companies who failed to get their production covered are the principle sufferers from the depression.

The outlook is mostly conceded to be pessimistic. Railroads are stocked up with full supplies. Coal is offered

down to 85 to 90c. and even the possibilities of a more or less protracted suspension in mining after Apr. 1 has failed to have any reviving influence on the situation. There are some optimists in the market, however, who feel that the buying has been so light recently that consumers stocks must be down to a low point, and this together with the possibility of labor troubles, will start a sharp buying movement about the middle of February.

We quote the New York market still weak but with the price base unchanged as follows: West Virginia steam, $2.60 @2.75 good grades of Pennsylvania, $2.75@2.85; best Miller Pennsylvania, $3.10@3.20; George's Creek, $3.15@3.25.

PHILADELPHIA

Zero weather stimulates demand for hard coal but conditions still slow. Mining restricted and the demand continues rather light. Bituminous market fails to rally in sympathy.

Anthracite—The local hard-coal market last week was more encouraging. The appearance of real winter weather early in the week stimulated the demand and increased consumption to a greater extent, even more than the most optimistic operator or dealer anticipated. The change was badly needed as the operators were contemplating half-time operations but conditions have now assumed a better aspect.

The continuous large shipments and the decreased consumption, because of the mild weather, had been seriously felt here for several months. Throughout the city yards and cellars were filled with coal that has not been required. The result was that since the middle of November there has been an exceedingly slack trade with the usual concessions in prices. Now the trade feels that it has come into its own at last and that normal activity is to be expected by the end of this month.

Bituminous—Conditions have not altered in the bituminous trade. Some coal is moving on contracts but new orders are scarce. Cheap grades can be bought at from 90c. to $1 but good grades are bringing $1.25@1.40.

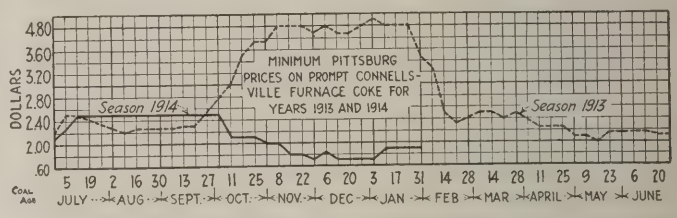
BALTIMORE, MD.

Low prices for soft coal continue. Demand not active and suspension of contract obligations in evidence. Retail hard-coal market fairly good.

The entirely unsatisfactory period of low-priced soft coals continues in this market. Demand is the worst for a close of January that has come to the trade for some years. All of the mining centers near-by are feeling the effects of this condition. Some of the largest mines are only working about two days per week. Even at that there is trouble in disposing promptly of the coal produced. One of the great troubles of the trade just now is the suspension of contracts.

Prices to the trade in West Virginia do not give any great encouragement. Slack was quoted down to 65 and 70c., and three-quarter gas around 75 and 80c. West Virginia steam coals were again quoted around 90c. West Virginia low-grade fuels were bringing from 90c. to $1, while best grades were offered from $1.20 to $1.25.

The anthracite coal trade is experiencing but a fairly good period. The weather as a whole is below the seasonal average, despite the occasional colder spells, and household trade has not been quite up to the mark. The much talked of merger of some twenty of the largest coal concerns here is now reported to be progressing favorably, and an announcement of its consumation may be made in the next couple of weeks.



In export lines fairly good progress is being made. Mexican shipments have been resumed, although they are not as heavy as they should be. The month of January, however, is expected to show a considerable tonnage moved from this port to foreign points.

CENTRAL STATES

PITTSBURGH, PENN.

Mine operations continue light, about 50% capacity, with prices being cut on prompt. Miners in convention at Indianapolis. Connellsville coke market quiet, with some operators showing low production.

Bituminous—Mine operations continue on a very restricted scale, little, if any, above 50% of full mine capacity. Many mines are closed entirely, while a few are operating at nearly normal. Prices continue to be cut by a number of sellers except in the case of slack, which is bringing $1@1.15, or above list. While there is little inquiry regarding contracts, full list prices would doubtless be quoted, and we repeat the list as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25, mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district. While the exact demands of the miners in connection with a scale for the new period beginning Apr. 1 are not known, it is well understood that the convention at Indianapolis will demand advances, together with the establishment of a straight mine-run rate, instead of a rate on screened coal with a differential for mine-run.

Connellsville Coke—The market has been quiet, but it maintains some show of strength. Prompt furnace coke is not openly offered below $1.90, though it is reported that one furnace interest, which refused to pay above $1.75 for any coke for this year, has picked up various odd lots at not over this figure. There is nothing doing by way of contracts, and two or three inquiries recently put out do not seem to have led to business. Several consumers covered for January only and their inquiries for February are expected within a few days. Some of the operators who held out for the full $2 price are showing extremely light operations. We quote: Prompt furnace, $1.90; contract furnace, $1.85@2; prompt foundry, $2.40@2.65; contract foundry, $2.40@2.65, per ton at ovens.

BUFFALO, N. Y.

Some improvement in the bituminous trade. Steady winter weather will soon restore activity. Surplus coal about gone. Anthracite more quiet. Coke stronger.

Bituminous—The bituminous trade in general agrees that the demand is better than it was a month or even a week ago. Both here and in Canada the consumer is beginning to take an interest and if the weather should become cold there will be plenty of business before long.

It is generally thought that the miners will go out at the end of March and as a rule the operators will not object. Indications point to a suspension of considerable length, followed by a short summer season with a good, paying trade. The feeling in the Philadelphia market, which depends largely on coal from nonunion mining districts is said to be more confident, but the cue of the operators is to let the miners do what they like in the matter. If they elect to go out they can do so and the suspension will be allowed to last till the market is out of surplus coal. Quite often this plan is not carried out very fully, but there seems to be every reason for it now.

Coke—There is also an added firmness in the higher grades of coke, the best foundry output being quite scarce in most markets, due both to restricted output and to a better demand. The lower grades are, however, plenty enough and promise to remain in surplus for some time. Prices are based on $4.50 for best 72-hr. foundry, with a slight upward tendency.

Anthracite—There is no stir in the anthracite trade, one reason being the heavy overstocks and the short duration of the occasional cold snaps. This trade is more affected by weather conditions than others and the fact that the winter in the West and Northwest is even milder so far than it is East has a distinctly depressing effect.. All anthracite mines are running on part time, and still there is some unsold coal from independent companies reported here and there. No premium has been obtained over the regular circular this season.

TOLEDO, OHIO

Domestic market was slightly stimulated by lower temperatures. Operators and dealers are still optimistic. Prices are holding up better than was anticipated. Little track coal and traffic moving well.

A briskness in the demand for domestic is noted as the result of some real winter weather in Toledo. Despite the return of milder temperatures toward the end of the week operators and dealers are still confident and the weather bureau has predicted continued lower temperatures. A strong demand for Pocahontas egg is evident and dealers need orders for lump coal in order to meet the demand for egg. Pittsburgh No. 8 is also strong.

Owing to curtailment at various factories steam coal is in light demand. Three of the sugar plants also shut down last week and this threw an extra tonnage on the market. One comforting fact in the local situation is that prices are holding up wonderfully well. Two weeks ago it seemed as though this would not be the case but the scarcity of various grades at the mines has served well to pull the former firm prices back to normal.

COLUMBUS, OHIO

Little change in the local trade reported during the past week. Weakness still apparent in both steam and domestic. Mining operations are not active. Little stocking reported as yet.

Continued slowness has characterized the coal trade in Ohio during the past week. The mild weather has affected the domestic trade adversely and dealers are not placing orders extensively. The steam trade is also quiet and on the whole the market is completely at the mercy of weather conditions. The price list of the middle of the month is being well maintained, although there are some instances of cutting to force trade.

Contrary to expectations there is little being done by steam users toward stocking up to guard against a suspension after Apr. 1. Manufacturing plants are accumulating stocks from their usual requisitions which are not being consumed because of the warm weather and slack orders. Some railroads which do not penetrate any coal fields are stocking up some, but on the whole most of the consumers are not worrying over the future.

In the domestic trade dealers are loath to place orders, even for future delivery. The continued mild weather has interfered with trade seriously and many of them have let a number of wagons go into other business. Small orders are the rule and the larger users who laid in their supply in the fall have not been compelled to place second orders. There is some demand for the fancy grades, but even these are weak.

Production has increased very slightly. In the Hocking Valley and Pomeroy Bend the output is estimated at 50% normal. In the strictly domestic fields it is only about 40% of the average, but eastern Ohio is increasing, reports showing about 55 to 60%.

What steam contracts expire at this time are being renewed without a great deal of trouble. The prices generally are the same as prevailed in 1913.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50 @ 1.45	.....	$1.50 @ 1.45	$1.50 @ 1.40
3-4 inch	1.35 @ 1.30	$1.20 @ 1.15	1.35 @ 1.30	1.35 @ 1.25
Nut	1.25 @ 1.20	.....	1.30 @ 1.25	1.25 @ 1.20
Mine-run	1.15 @ 1.10	1.10 @ 1.05	1.15 @ 1.10	1.15 @ 1.10
Nut, pea and slack	0.80 @ 0.75	.....	0.85 @ 0.80	0.80 @ 0.75
Coarse slack	0.70 @ 0.65	1.00 @ 0.95	0.75 @ 0.70	0.70 @ 0.65

DETROIT, MICH.

Some indications of industrial improvement had a mildly stimulating effect, but the market still rules dull at a discouraging low level. Demand fails to materialize as a result of the strike talk. Negotiations on contracts for the new year.

Bituminous—There is some improvement in new business, but track and spot coal remain about the same with perhaps a decrease in the supply of cheaper grades. Interest is beginning to focus on the making of new contracts, and there are rumors of an advance of 10c. per ton over last year's figures. It is doubtful, however, if operators will succeed in maintaining an increase of even 5c. per ton.

Anticipated labor troubles, Apr. 1, have failed to create any renewed activity at the mines. Some indications of improvement in general industrial manufacturing had a mildly stimulating effect, but the reports of an almost unprecedented surplus of idle coal cars was a weakening factor in the situation. The domestic market continues dull and uninteresting at a discouraging low level. The colder weather of last week created some demand, but coal came in, in unlimited quantities to meet it. Local coal men have hopes, however, of a profitable season this year.

Anthracite—The supplies of hard coal exceed requirements, and it is now almost certain that stocks will be carried over into the spring.

Coke—Coke is slightly more active, local ovens which have been closed for the past month having gone in blast. Connellsville is quoted at $2.25, Solvay at $3.25, and gashouse at $3 f.o.b. ovens.

HAMPTON ROADS, VA.

Coal accumulation slightly above normal. Norfolk & Western Ry. makes record day's dumping. Some shippers still short and prices holding remarkably well.

In consequence of only a fair movement from tidewater the accumulation of coal is somewhat larger than it has been for some months. The demand from all sources has been particularly light during the entire week. In addition to the falling off in cargo vessels there has also been a decrease in the arrival of bunker steamers. The falling off in the latter is probably due to light export shipments from the Southern ports. Although there is more than the normal supply on hand some of the largest shippers are short of coal for tonnage actually in port.

Even with the light demand it is impossible to find that there has been any cut in prices. Some spot sales have been made during the week but it is impossible to ascertain at what prices. It is not believed, however, that they were made below the regular circular.

Notwithstanding the light shipments from Hampton Roads the Norfolk & Western Ry. on Jan. 19, had the heaviest day's dumping ever made over the piers of that road at Lamberts Point. Five barges and a like number of cargo steamers were loaded with 832 cars, a total of 36,692 tons. This is 2834½ tons more than was dumped on Dec. 22, 1913, the largest previous record. The total dumpings for December 22 was 33,857½ tons.

LOUISVILLE, KY.

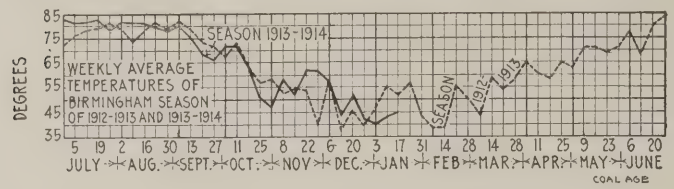
Consumption abnormally low and few dealers are inclined to buy. Large surplus of railroad cars. Mine operations much restricted. Price cutting becoming general.

The coal trade is still facing an almost unvarying continuance of mild weather, one or two days of comparatively low temperatures early in the week not being sufficient to affect the market appreciably. This has made domestic coal increasingly difficult to move, inasmuch as the stocks accumulated during the past month still remain much too large. Consumption has been at an abnormally low point and domestic users are not inclined to buy in view of the approach of the second month of the year and the last of the winter.

The present excellent car supply, and the rapidity of the movement are largely due to the small volume of business as compared with a normal season. It is reported that many mines are only working two days a week, while other operations have stopped entirely, the supply of coal already in the hands of the trade being excessive. The high stage of the Ohio for the past month has enabled the river companies to replenish their holdings considerably, so that there is a large supply of coal in all quarters with little demand.

Quotations on the best grades of eastern Kentucky block are made at $1.85, but this is shaded to effect a sale. It might be said that there is practically no market for the domestic grades, and hence no figure which would represent a fair average price. The steam market is somewhat more satisfactory, the supply being larger than the limited operations would seem to provide, while prices are fairly good, considering the general state of the market. For the first grades 85c. is about the average figure, while for second qualities and western Kentucky screenings 15 to 20c. lower is the market.

SOUTHERN AND MIDDLE-WESTERN

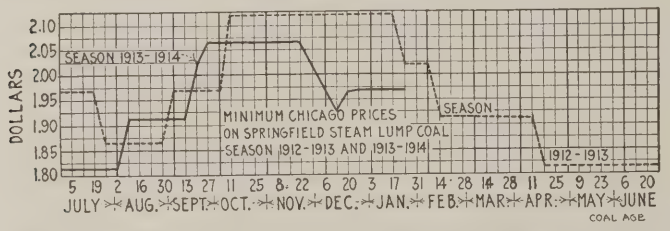


BIRMINGHAM, ALA.

Very little change in coal market. Furnace and foundry coke still quiet and blacksmith coal satisfactory. Large sales of pig iron with prices slightly below $11. Car situation improving.

From the indications about ten days ago, it seemed that the coal market was picking up, but the past week has brought little improvement, either on lump or steam coal, and while the demand is slightly better on both grades than it was two weeks ago, still, it is far below the average for this season of the year. As a rule, all mines are being rushed to their full capacity to fill lump orders, but the operators are experiencing some trouble in keeping their output moving

regularly. The steam trade is not in a much better condition, though the past week has brought out inquiries for contracts amounting to approximately 50,000 tons.



The conditions generally are not satisfactory. Furnace and foundry coke are still quiet, though prices are holding up. Blacksmith coal is moving in about its normal tonnage. Furnaces report large sales of pig iron, one operator reporting approximately 25,000 tons sold for the week, the base price being slightly below $11 for 2 Foundry f.o.b. Birmingham. The car situation has improved to some extent, and little trouble is being experienced for want of equipment.

CHICAGO

A continuation of warm weather and light buying has caused some prices to reach new low levels. Steam users are not in the market except for comparatively small amounts. A renewal of activtiy in the southern Illinois fields has been noted.

Lack of usual buying by consumers has been a noticeable factor in the anthracite trade. Consumption in apartment houses and other dwellings is about normal, but there has been a marked falling off in other business. Easier conditions prevail so far as smokeless is concerned. It is not difficult to obtain a lot of mine-run from small producers at $1.25 a ton, although the larger operators are still demanding $1.40, the mines. The demand for lump and egg is fairly good, the market being firm at from $1.85 to $2.25, the mines. The circular price of Hocking remains at $1.75, although there are many sales at $1.50 for the best grade.

The attitude of many concerns in restricting expansion until they can ascertain what Congress proposes to do on the subject of anti-trust legislation is having an important effect on the steam trade. Smaller concerns are following their example and the result is slow business.

An increase in activity has been noted in the southern Illinois fields. The major producers of Franklin County coal are selling lump and egg at $1.65@1.75. The action of the railroads and some other large consumers of steam coal in making purchases for storage purposes has had a beneficial effect on the market. A reduction of 5c. a ton in Springfield steam lump and mine-run and a cut of 10c. in the price of screenings has been recorded. Indiana operators report light buying and few signs to indicate that business will be accelerated to any marked degree in the near future. The current needs in furnace and foundry coke are being taken care of by small purchases. Few contracts are being closed. Carterville producers are selling lump, egg and No. 1 washed at $1.50 to $1.75.

Prevailing prices at Chicago are:

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic lump	$2.32	$2.55@2.80	$2.27	
Steam lump	1.92		1.97	
Egg		2.55@2.80		$3.90@4.30
Mine-run	1.32	2.30	1.87	3.30@3.45
Screenings	1.47	1.75	1.47	

Prices quoted for Harrisburg coal are: Domestic lump and egg, $2.55@2.85; steam lump, $2.25; mine-run, $2.25; screenings, $1.75; No. 1 nut, $2.55@2.85; No. 2 nut, $2.55.

Carterville prices are: Lump, egg and No. 1 washed, $2.55@2.85; No. 2 washed, $2.55.

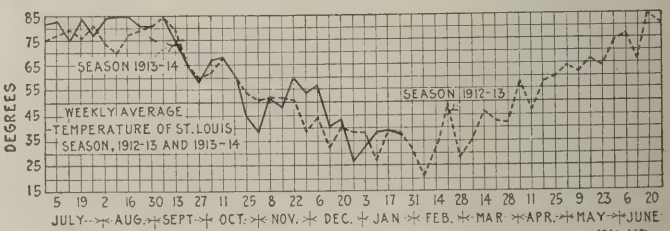
Coke—Connellsville, $5.25@5.50; Wise County, $5@5.25; byproduct, egg, stove and nut, $4.90@5; gas house, $4.65@4.75.

INDIANAPOLIS

Mild weather a check to good business. Dullest January on record at the mines. Brief spells of cold weather prevent demoralization, but some bargains being offered. Miners making about half-time.

Continuation of mild weather tends to make conditions dull in the coal industry. It would be unprecedently so, if there were not brief interspersions of cold weather that make it necessary for the domestic consumers to keep an ample supply on hand. Operators say that, taking the season as a whole, the 21,000 miners of the state have not made better than half-time. They cannot recall a January when mining operations were so slow. Better reports are coming from the iron and steel industry, however, and this means an improvement in the coal mining industry.

There has been a check to the buying caused by fear of a suspension of work after Mar. 31, when the present wage contract runs out. Operators and miners have both passed resolutions opposing any shut-down during wage negotiations, no matter how prolonged these may be. The final action concerning this, however, is in the hands of the interstate joint committee that meets in Philadelphia, Feb. 3. The feeling is general that there will be no material change in the wage schedule and some Indiana operators are so certain of this that they are trying to make yearly contracts on the same wage basis as last year. The largest consumers also seem to be taking it for granted that if there is a suspension it will be a short one.



Mines that do a large part of their total business on contracts are holding prices steady but some bargains are being offered at retail, probably indicating concessions made by some mines. Several yards have cut prices 25c. all down the line and on some coals 50c. a ton. One of them offers "good, clean Indiana lump, best quality," at $2.90 a ton, as against $3.50 the general price, and Hocking lump at $4.20, as against $4.75.

ST. LOUIS

Market conditions continue adverse, owing to mild weather, and failure of big steam users to put in usual storage supplies. Colder weather predicted which it is hoped will bring better conditions. Rumors from the strike zone.

Market conditions here continue in practically the same rut as for the past several weeks. Continued warm weather has kept business in perhaps a worse condition than it could possibly be in the middle of the summer. Usually at this period of the year, preceding the termination of a wage agreement between the miners and the operators, there is an unusual amount of storage coal bought, but there is little if any being purchased at this time, principally because the railroads have been stocking up gradually for several months, on account of the attractive prices.

Manufacturers, as a rule, are not expecting at the present time to place for any great amount of storage coal. They are under the impression that the miners and the operators will accede to the demands of certain railroad interests. It seems that one of these demands is that operators on certain railroads have been instructed by the road's officials to do everything possible to prevent a suspension and they will go to the convention instructed this way. On the other hand, the small operators would welcome a suspension of from two to three months. It would bring good prices now and enable them to shut down during a period when there is no business under the most favorable conditions.

Locally, the screenings market has dropped off and seems to be getting lower, and strange to say, the same applies to the screened sizes. All these latter have dropped during the past week, and there is no immediate indication that there will be any advance soon, although there now seems to be a likelihood of St. Louis getting a little real winter weather.

Anthracite, smokeless and coke are moving slow; the first is usually a demurrage proposition at East St. Louis.

The prevailing market is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump				$0.90@1.00
3-in. lump			$1.40	
6-in. lump	$1.25 @ 1.50	$2.25	1.50	1.15@1.25
Lump and egg	1.85 @ 2.15			
No. 1 nut	1.15 @ 1.40			
Screenings	0.75 @ 0.80			
Mine-run	1.10 @ 1.20			
No. 1 washed nut	1.60 @ 1.75	2.25	1.60	
No. 2 washed nut	1.25 @ 1.35		1.25	
No. 3 washed nut	1.15			
No. 4 washed nut	1.05			
No. 5 washed nut	0.50			

KANSAS CITY, MO.

Operations at the mines much restricted. Market dull and hinging entirely on weather conditions. Prices resisting any tendency to decline.

Remarkably variable weather has prevented the coal operators from making much of a gain during the past week. Arkansas mines have operated only about half-time. Those in Kansas and Missouri have done a little better, as a rule, running about four days. The weather, the key to the situation, has been inconsistent, providing extreme cold one day and balmy breezes the next. The market has been steady, but far from strong.

OGDEN, UTAH

Moderate weather prevails and mines idle because of no orders. Operators believe season's demand for coal is over and are putting mines on half-time basis. Freight rate reduction to Northwest. Shipments to sugar factories discontinued.

During December 1913 the operators had a hard time to keep orders coming in fast enough to take care of the production. January 1914 opened up weak and it has been a continual fight to dispose of the output. Many of the operators kept their mines running in order to hold the men, thinking January would bring some winter weather, and increase the demand for coal; however by January, 15, it was the general impression that such would not be the case. Reports from Portland, Walla Walla and Spokane show that weather conditions are above normal and that these points have had practically no winter weather. One report states that the rose bushes in the parks at Spokane show indications of budding.

All of the sugar factories have completed the season's run and shipments of slack and steam coal have been discontinued. This has caused a surplus of slack coal at the mines. There is also a surplus of nut coal and prices have been lowered at times. A permanent reduction of 25c. on nut for shipment to Nebraska was established early in January in order to move the surplus.

The Union Pacific, Oregon Short Line and Oregon, Washington Railroad & Navigation Cos. announced a reduction in the freight rate on coal from Rock Springs effective Jan. 8, to points northwest of Huntington, Oregon. This reduction was made necessary by the commission's reduction in the freight rate on coal in the Sheridan district of northern Wyoming. These coals originate on the C. B. & Q. R.R. and come in direct competition with Rock Springs coal in Washington, Oregon and northern Idaho. The reduction in the Rock Springs rate varies from 25c. to 90c. per ton.

Present quotations are rather weak and unsteady on the following basis:

	California	Nebraska	General
Lump	$3.00@3.50	$3.00	$2.75
Nut	2.50@3.00	2.00	2.25
Mine-run	1.85	1.85	1.85
Slack	1.00	1.00	1.00

PRODUCTION AND TRANSPORTATION STATISTICS

PENNSYLVANIA RAILROAD

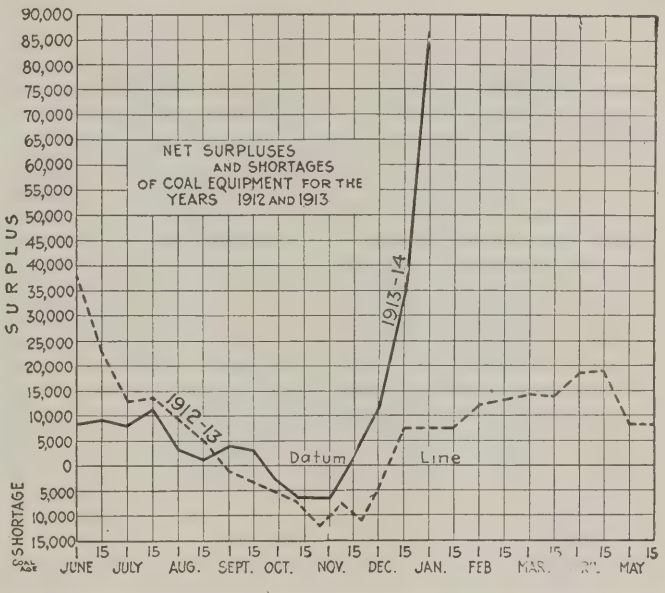
The following is a statement of shipments over the P. R.R. Co.'s lines east of Pittsburgh and Erie for December and the twelve months of 1912 and 1913 in short tons:

	December		Twelve Months	
	1913	1912	1913	1912
Anthracite	1,012,125	1,036,717	10,711,335	10,312,348
Bituminous	4,354,729	4,271,702	51,526,267	46,434,187
Coke	880,962	1,242,882	13,892,825	13,371,345
Total	6,247,316	6,5 1,301	76,330,427	70,117,880

NORFOLK & WESTERN

The following is a statement of the tonnage shipped over this road during December, 1913, and the twelve months, as compared with corresponding periods of 1912 in short tons:

	December		Twelve Months	
Coal	1912	1913	1912	1913
Tidewater, foreign	84,083	150,886	1,343,311	1,542,950
Tidewater, coastwise	258,216	331,829	3,583,283	3,805,847
Domestic	1,355,189	1,353,108	17,716,575	18,543,672
Coke				
Tidewater, foreign	.....	575	52,762	31,082
Domestic	134,763	116,730	1,416,856	1,499,302
Total	1,832,251	1,953,128	24,112,787	25,422,853



THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Jan. 15, as follows:

	Surplus	Shortage	Net*
New England Lines	633	0	**633**
N. Y.; New Jersey, Del.; Maryland; Eastern Penn.	22,362	350	**22,012**
Ohio; Indiana; Michigan; Western Pennsylvania	40,065	109	**39,956**
West Virginia, Virginia, North & South Carolina	4,419	254	**4,165**
Kentucky, Tenn.; Miss.; Alabama, Georgia, Florida	7,347	55	**7,292**
Iowa, Illinois, Wis., Minn.; North & South Dakota	3,609	15	**3,594**
Montana, Wyoming, Nebraska	460	0	**460**
Kansas, Colorado, Missouri, Arkansas, Oklahoma	2,770	0	**2,770**
Texas, Louisiana, New Mexico	468	6	**462**
Oregon, Idaho, California, Arizona	5,016	0	**5,016**
Canadian Lines	0	0	0
Total	77,149	789	**86,360**

	Sept. 15	Oct. 1	Oct. 15	Nov. 1	Nov. 15	Dec. 1	Dec. 15	Jan. 1
Surplus	8,714	7,953	6,614	6,720	10,520	17,621	36,425	72,535
Shortage	7,731	10,393	12,502	12,595	8,477	5,095	2,295	57

***Bold face** type indicates a surplus.

FOREIGN MARKETS

GREAT BRITAIN

Jan. 16—The position is unchanged, buyers being still able to purchase upon easy terms for prompt loading, and as regards forward shipment, inquiries are being held off the market. Outputs are very heavy.

Quotations are approximately:

Best Welsh steam	$4.56	Best Monmouthshires	$4.17
Best seconds	4.44	Seconds	4.05
Seconds	4.26	Best Cardiff smalls	2.64
Best dry coals	4.56	Seconds	2.46

The prices for Cardiff coal are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both net, exclusive of wharfage, and for cash in 30 days.

BELGIUM

Belgium imports and exports for 11 months ended November, 1912 and 13 were:

	Imports		Exports	
	1912	1913	1912	1913
Coal	8,116,243	7,409,763	4,498,231	4,652,783
Coke	1,032,131	860,784	1,013,221	923,206
Briquettes	430,612	391,744	580,835	578,752

COAL FREIGHT DECISIONS

Suspension Docket No. 242—Engine-switching charges

Proposed increase in rates on interstate shipments of coal from Chicago, Ill., to Ravenswood, Ill., and reduction of amount of absorption on such shipments by line carriers found not to be justified and suspended tariffs required to be withdrawn.

Financial Department

Lehigh & Wilkes-Barre Coal Co.

This company reports for the year ended June 30, as follows:

	1913	1912	1911
Rec., all sour	$20,628,564	$18,742,623	$16,879,575
Op. exp., tax, etc	15,019,733	14,982,262	13,406,193
Dep. coal land fd	.....	.....	.....
Net	5,608,831	3,760,361	3,473,382
Interest	724,690	814,390	814,390
Sinking fund	461,089	360,000	460,000
Surplus	4,423,051	2,485,971	2,198,992
Ded. to com. break. and deb. coal in stock	.....	.....	.....
Less feder inc. tax	.....	.....	17,193
Bal. surp	4,423,051	2,485,971	2,181,798
Dividends	1,197,462	1,197,625	1,197,625
Refund. debt	.....	.....	.....
Profit and loss	3,225,588	1,285,346	984,173

The number of tons of coal mined and shipped during the year was 5,189,221, an increase of 1,202,795 tons, and 541,559 tons were purchased, a decrease of 144,969 tons, as compared with the previous year. The tonnage sold was 5,678,373, an increase of 497,914 tons over previous year. The tonnage of prepared sizes sold, including lump, equaled 66.73%, and of pea and smaller, 33.27%.

The amount in the sinking fund for the consolidated loan on June 1, 1913, was $1,426,829, of which all but $641 cash was invested in interest-bearing bonds. The year before the amount in the fund was $932,743.

President Baer says:

"The several leases under which the Parrish Coal Co. were operating on this company's property were to expire June 1, 1916. It was deemed advisable not to renew or extend these leases, and in order to properly conserve the company's property it was decided to purchase the property, imporvements, equipment, etc., of the Parrish Coal Co., and possession was taken on Feb. 1, 1913.

"Under the statute applying to counties with a population of more than 300,000, the assessment of property in Luzerne County is no longer under the control of the county commissioners, but is placed in the hands of a board of assessment appointed by the court. This board has just completed its work, and has made a very marked increase in the value of property generally, particularly coal lands. This has necessitated further appeals, and, from present indications, it will be some time before an equitable basis of valuation on coal property is finally determined.

"On June 27, 1913, an act assessing a tax of 2½% of the value at the mines of coal prepared for market became effective. This company's tax under this act will be approximately $375,000 per annum.

"To facilitate the movement of coal from tidewater to eastern points, the sea tugs and barges owned by the C. R. R. Co. of N. J. were purchased at an appraised valuation. The fleet consists of three tugs and fifteen barges, with a carrying capacity of 20,000 tons.

"In compliance with the decision of the Supreme Court of the United States in the matter of the so called 65% contracts, all of such contracts held by this company were at once cancelled, and no coal has since been purchased, except in special cases, in small quantities, of a particular size."

The balance sheet as of June 30, shows total assets $37,805,911, an increase of $947,321. The working assets total $6,762,205 and current liabilities $918,155.

At the annual meeting of the company, President George F. Baer and the directors were unanimously reëlected. The board consists of George F. Baer, George F. Baker, Samuel Dickson, Edward T. Stotesbury, Andrew H. McClintock, Charlemagne Tower and Thomas A. Wright.

Taxes on Coal Bonds

The "New York Times Annalist" has prepared the accompanying data re taxes on coal bonds. Four definitions of status are used as follows:

(1) **Free,** meaning that the corporation pays;

(2) **Taxable,** meaning that the holder pays;

(3) **Company has refused to pay,** which means generally a debatable interpretation of the mortgage provisions by the corporation, and

(4) **Doubtful,** which means that the provisions of the mortgage are obscure and that interpretation is in suspense.

As a rule, corporations have been liberal in their interpretation of obscure provisions; a number have rather agreed to pay the tax than to dispute the point. The list follows, in the alphabetical arrangement of the Stock Exchange sheet:

Buffalo & Susquehanna Iron Co. 1st 5s,	June 1, 1932	Free
Clearfield & Bituminous Coal Corporation 1st S. F. 4s,	Jan. 1, 1940	Free
Colorado Fuel & Iron Co. Gen. S. F. 5s,	Feb. 1, 1943	Taxable
Colorado Fuel Co. Gen. 6s,	May 1, 1919	Taxable
Colorado Industrial Co. 5s,	Aug. 1, 1934	Free
Consolidation Coal Co. 1st & Ref. S. F. 5s,	Dec. 1, 1950	Free
Consolidated Indiana Coal Co. 1st S. F. 5s,	June 1, 1935	Free
Continental Coal Co. 1st 5s,	Feb. 1, 1952	Free

Saves Stops Saves Trouble

It saves break-downs and output lost by stoppage.
It does not so soon stretch loose and slip.
It saves you take-ups and repairs.
It lasts longer and costs less per year.

REASONS:

Its long life comes from our special toughening process. Also from our close assortment of the leather to exclude any pieces that would cause weak spots.

Our stretching is unusually thorough. Skillful workmanship secures strong, flexible joints.

TWO INSTANCES:

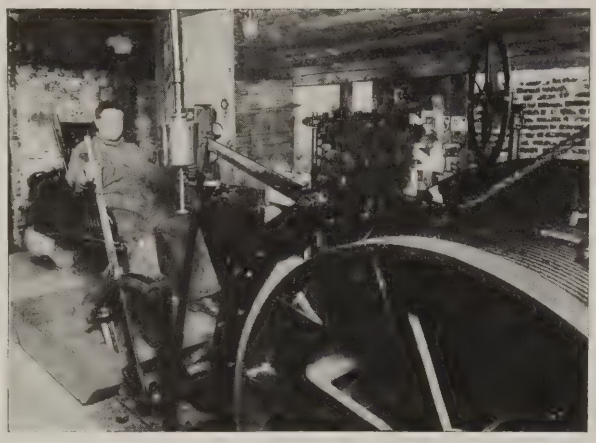
A certain concern told us that 23 years previously they refitted their mill with Rhoads Leather Belts, all of which but one were still doing good work.

A planing mill wrote in 1911 that in 1894 they equipped throughout with Rhoads Belting and had had very satisfactory service. Some of the belts, though running almost continually since the date of installation, were still in good condition, and these were on hard drives.

IN COLLIERIES:

Similar satisfaction in collieries is shown by long use of Rhoads Belts by big coal companies.

Write for samples of our belt record tags, and try them on Rhoads Belts and others in comparison.



For damp places, use Rhoads "Watershed Oak."

Westinghouse Motor Driving Mine Hoist.

Maximum Output in a Given Time Is Assured from Hoists Equipped with Westinghouse Electric Motors

These Motors have been designed with the knowledge that any accident to the hoisting equipment will not only impair production until service is re-established, but may also cause damage of the most serious nature.

Hence they are made as reliable as it is possible to make any motor. Mechanically they are far stronger than the service for which they are intended requires, and electrically they will withstand heavy overloads without injury.

The bearing brackets are heavy and massive, the bearings large in area, the windings are so braced that they cannot chafe, and the shafts are extra large in diameter and **made of axle steel,** the best material to withstand severe stresses.

Write to the nearest office listed below for full information about Westinghouse Motors for Mine Hoists.

VOLUME 5 FEBRUARY 7, 1914 NUMBER 6

CONTENTS

WITH PRINCIPAL ARTICLES SUMMARIZED

*Illustrated Article

FOREWORD: *Page* 231

Some remarks concerning the evil practices of shyster lawyers who hang about coal camps and hatch up fake damage suits. One mine manager solved the problem by employing a private detective to follow the shysters.

IDEAS AND SUGGESTIONS: *Pages* 232-233

Efficiency When Approaching a Limit—A Plea for More Frequent Inspection of Mines—Safety First on the Man-Trip—Superfluous Legislation.

*PURCHASED POWER AND BITUMINOUS COAL MINING: *Pages* 234-239

There has been a vast increase in the amount of central-station power purchased by coal producers during the past five years. The principal uses and advantages of this source of power to the operator are here discussed. A. E. Rickards. COAL AGE, Vol. 5.

*HYDRO-ELECTRIC POWER FOR WEST VIRGINIA COLLIERIES: *Pages* 239-242

A description of the generating and distribution system of the Appalachian Power Co., which furnishes electric energy to many mining operations in the Pocahontas and adjoining fields. C. A. Tupper. COAL AGE, Vol. 5.

THE SPIRIT OF MANAGEMENT: *Page* 242

Poem by Berton Braley. COAL AGE, Vol. 5.

*SAFETY IN WEST VIRGINIA: *Pages* 243-247

Some of the means employed by the United States Coal & Coke Co. to prevent accidents. Frank K. Kneeland. COAL AGE, Vol. 5.

*CONNECTING MOTORS TO MINE FANS: *Pages* 247-248

It is frequently advantageous in mine ventilation to be able to shift the fan drive from one motor to another. Two arrangements for accomplishing this end are here described. H. J. Booker. COAL AGE, Vol. 5.

THE INDIANAPOLIS CONVENTION: *Pages* 248-250

With only about a dollar to spend per man on the coming strike in the spring, the United Mine Workers of America was inclined to be conservative, though men were present who figured every dollar over a hundred times and found use for all. There is plenty of evidence that the direct-action element will soon replace the socialists as disturbers in the organization. COAL AGE, Vol. 5.

PROPOSED LAW FOR KENTUCKY COAL MINES: *Page* 250

*FIREDAMP RESERVOIRS IN ROOM-AND-PILLAR WORK: *Pages* 251-252

Cavities above coal workings, when caving has taken place, often contain large quantities of gas which cannot be removed by ventilation. It is suggested, therefore, that holes be drilled for the purpose of tapping these reservoirs, which are a standing menace to the lives of the miners. Frank Haas. COAL AGE, Vol. 5.

EDITORIALS: *Pages* 253-254

Purchased Power—The Ethics of Unionism—Making Men—The Coming Spring Agreement.

LEGAL DEPARTMENT: *Page* 255

MUST A CONTRACT TO SELL COAL BE IN WRITING? By statute in most states, agreements for sale must be evidenced by signed writings, if the price exceeds a fixed amount, if no part of the price is paid, and if no part of the property sold is accepted and received by the buyer. What the courts have held in coal-trade cases. A. L. H. Street. COAL AGE, Vol. 5.

SOCIOLOGICAL DEPARTMENT: *Pages* 256-257

More Club Rooms for Mine Workers—*Concrete Vaults in Colliery Villages—Restoratives—Vineyard Orchards in Pocahontas Region—Work of Rescue Car in Arkansas.

DISCUSSION BY READERS: *Pages* 258-260

Rope Lubrication. Letter No. 1—Fan Ventilation—The Certificate Law. Letters Nos. 16 and 17—Colorado Strike Investigation.

The Weekly Ad-Talk Page

I am ashamed neither of my work nor of the way it is done. I like explaining its merits to the huge majority who don't know good work from bad. It does them good; and it does me good, curing me of nervousness, laziness and snobbishness. I write prefaces as Dryden did, and treatises as Wagner, because I can; and I would give half a dozen Shakespeare's plays for one of the prefaces he ought to have written. I leave the delicacies of retirement to those who are gentlemen first and literary workmen afterwards. The cart and trumpet for me. *George Bernard Shaw.*

One of the best-advertised individuals in the world is George Bernard Shaw. He is as well known as Emperor William of Germany or any other potentate, as famous as Mrs. Pankhurst, or Teddy Roosevelt or even Jack Johnson. He is so celebrated, in fact, that a newspaper anywhere in Great Britain or in this country has simply to refer to him by his initials and readers know who it means.

How has George Bernard Shaw come by this exceedingly wide-spread reputation? First of all, because he has a good line of wares—clever plays, so clever indeed that most people have to get used to them before they understand them—and, in the second place, he has this wonderful ability of his to get talked about, to say the unexpected thing, the thing that will be widely quoted. In short, he has the ability to advertise himself and his wares.

"I leave the delicacies of retirement to those who are gentlemen first and literary workmen afterwards. The cart and trumpet for me," says G. B. S.

In saying so he voices the spirit of the modern manufacturing world: *First make a good product and then get out and advertise it—sell it.*

In a great many ways George Bernard Shaw is a pioneer. He is a literary genius who in defiance of the laws and traditions of a host of lesser literary men has come out and advertised himself and his ideas in the most flamboyant fashion.

"It's not dignified!" shouts the host of lesser literary lights.

But does George Bernard Shaw care? Not one little round yellow mustard seed.

As a parallel case, take some big and progressive manufacturer who begins to advertise his wares in a big and progressive way and a host of smaller manufacturers will chorus: "It isn't dignified! It isn't ethical!"—or some such tommyrot.

As a matter of fact, any man or firm or corporation which makes a good product whether it be plays or pianos, books or bathtubs *owes* it to himself and to the public good to advertise it.

Do you think a doctor who discovers a remedy for cancer (not a quack remedy but a real one) should hide his discovery, keep it to help a few selected patients? No! He should spread the news of his discovery from where the sun rises to where it sets, so that the whole of humanity can benefit.

Do you think that a manufacturer who builds a better hoist or fan should restrict himself to selling it among a few friends who happened to be mining men? Not by a long shot! He should give every one a chance to buy it. He should advertise it in the pages of his technical paper.

The best part of it is, these progressive manufacturers in the technical field do advertise. There are very, very few of them so tied down to the past that they still think advertising "undignified."

If there is any worthwhile new machine or device built that will help the mining profession, you can count upon seeing it advertised in *Coal Age* shortly after it is put on the market.

But the advertiser cannot do it all. You don't get any benefit from George Bernard Shaw's advertising until you read—or still better, *see*!—one of his plays.

And you don't benefit by the advertising in *Coal Age* until you get the habit of, not only scanning it, but *studying* it—every week.

COAL AGE

Vol. 5 NEW YORK, FEBRUARY 7, 1914 No. 6

"Still have I borne it with a patient shrug
For sufferance is the badge of all our tribe."

Mr. Mine owner, sit down for a few moments and recall the fake damage suits that have been hatched around your diggings by shyster lawyers during the past year, and then read the above quotation by Shakespeare. Are you proud of "our tribe?"

Nearly every state in the union has a bar association and each of these state organizations meets yearly and assures the public at large that they will not countenance *champerty* in their ranks.

After these solemn declarations, *champerty* ought to cease, but it doesn't. Possibly the rank and file of the legal profession assume that the layman doesn't understand what *champerty* means and so decide that they may practice it with impunity around all of the coal-mining camps that come under their observation.

Here is a part of the definition of *champerty*, given by the Century Dictionary: "The purchase of a suit or the right of suing. Champerty is a punishable offense by common law, and in some jurisdictions, by statute." If we ever get educated to a point where champerty is in every man's vocabulary, the word shyster will only survive in dictionaries.

Year by year the cost of liability insurance to coal-mining companies has risen, until it now has reached a point, in some states, where it is all but prohibitive to a small operator; and even at that, the liability companies are not declaring dividends. Still it appears the worst is yet to come.

Some operators are beginning to wake up to the fact that it is time to help the public to understand that these drains saddled upon the coal-mining industry must eventually raise the price of coal to the consumer.

A majority of the coal operators are merely practicing the sufferance act. However, a few colliery owners are taking steps to place scare-crows around their plants, for the especial benefit of the shysters.

We know of one manager who employs a detective occasionally, to follow the shysters and their agents, when they become active around his camp. It may surprise you to know that these human blots on the legal profession have decided that it doesn't pay to buy the accident claims that originate at that mine.

Most any farmer can improvise a scare-crow. Try it.

Ideas and Suggestions

Efficiency When Approaching a Limit

By W. Va. Superintendent

In resultants varying as the forces, we are apt to neglect certain factors which become operative when a limit is being approached. We say, "With a lever long enough and a fulcrum strong enough, we could move mountains; with pressure and cold sufficient, all matter might be solidified; with a telescope of high enough power, we could study the inhabitants of our neighboring planets; and separating the molecule is only a matter of sufficient microscopic power." Yet, in spite of a certain advance toward these ends, difficulties have always appeared which were not encountered when working farther from the limit.

What seems a much simpler problem is the calculation of the equipment and the number of miners to produce a given tonnage. We consult our records and find that the average miner for a given seam of coal, with given equipment, is capable of producing six, seven or eight tons per day. We then multiply the number and increase the equipment and expect to get a proportionate increase in tonnage. That is, with 100 men you have been able to produce 800 tons per day. If 100 men in one day produce 800 tons, how many tons per day will 200 men produce? That sounds just like the mental arithmetic of the lower grades, and we have but to shut our eyes in order to see the dozens of small hands flying up, eager to give the answer—1600 tons, and that answer calls for 100 per cent.

An Increase in the Number of Miners Does Not Bring a Corresponding Increase in Tonnage

But, in actual practice, if 1600 tons is approaching the calculated capacity of the mine, we find that an increase from 100 to 150 miners makes the efficiency of the miner drop to something below eight tons, and as the number rises toward 200, the number of cars per man takes another drop, so that when you have your 200 miners, they are producing considerably less than the 1600 tons, or an increase of 50 per cent. in miners has increased the output perhaps 25 per cent. Of course, you are getting a nice tonnage, but it is falling short of the calculation. At this point men begin quitting, partly because their earning capacity is not what it was when there were fewer men.

If the fall in efficiency were an average drop, affecting all miners alike, perhaps the effect of working near capacity would not cause any considerable dissatisfaction, but it is more probable that the last comers have suffered most. The old men have a way of looking out for themselves and taking advantage of car service and the cutting of their places, so the men most affected, finding that they can work to better advantage in a mine that is not so crowded, leave with more or less disgust, take some of the others with them, and pronounce the plant "no good."

Another possible factor to be counted on in approaching a limit of capacity is the chance that the last men hired may be "floaters." Every mine has its nucleus of old miners who stay while others come and go, and it is these men who are getting the tonnage when the mine is operating at less than capacity. Perhaps, too, they may realize that an increase in men may lessen their chance for service and, in a quiet way, discourage others who come around looking for work.

The Capacity of Officials for Service Is Not So Flexible as Many People Believe

We are too sure that results will come in arithmetical proportion, that is, double the men, double the tonnage. We are apt to forget the factors that show up when approaching a limit. Perhaps we are too quick to take it for granted that the man who can handle 100 men can keep 200 up to efficiency, or that the boss looking after 25 can attend to 50 just as well. In the calculation of equipment, the mine has been provided with a superintendent, mine foreman and assistants. Their capacity for service is supposed to be flexible enough to meet the demands of the mine up to the point of capacity; but, nevertheless, when their routine of daily duties has been established on a basis of only partial capacity, when the struggle comes of maintaining a maximum, it requires ability and real devotion to duty to rise to the increasing demands on time and attention.

A certain car equipment has been calculated as adequate for the limit of capacity, but when they have been distributed in a certain way for 100 men, it requires some adjustment to make a satisfactory distribution for an increasing number of men. The machines should be able to cut for 200 men, but the habits of the runner must change as he approaches capacity. A breakdown may have little effect when there is a chance to shift in other machinery, but at full capacity every delay is felt immediately by someone. Working machinery to its limit multiplies the liability to breakdown, and an injury to it while operating at its full capacity is apt to be more serious than when it is running with reserve power. And so we might go on showing why so few of our mines ever reach that capacity for which they were planned.

We are all familiar with the old preachment that success and achievement are measured by the small margins over and above what is fairly good, and that the world's record makers are champions by reason of their fractions of seconds, inches and ounces. The highest was accomplished by efficiency as it approached a limit, and the struggle to make those fractions stands out as the real point of excellence.

Applied to tonnage getting, the real struggle also begins when the mine is approaching its maximum. At a good mine with good, new equipment, favorable surroundings, and a fair organization of foremen, almost any man ought to get tolerable results from a partial complement of miners, but the man who is working at capacity and holding his men is about as rare as cham-

pionship material, or as that long lever with fulcrum "strong enough." Solving the problem is at best like extracting the square root of an imperfect square to the "n-th" decimal place.

A Plea for More Frequent Inspection of Mines

By a Miner*

In view of the fact that hundreds of men lose their lives annually in the mines, by falls of coal or rock, and considering that we have splendid mine laws that are intended to safeguard the miner and protect the property of the mine owner, it seems to me that the factors most responsible for fatal mine accidents due to falls of roof or coal, are the carelessness or ignorance of the miner and the lack of sufficient official inspection of the working places.

In many mines, where the working places are scattered over a large area, neither the mine foreman nor his assistant is able to reach some of these places, until several hours after the men commence work. Most of the serious accidents that have come under my observation could have been avoided by closer inspection, or, I would say, a more frequent inspection by the foreman or his assistant.

Suppose, for a moment, there are 20 or 25 men working on a heading; if an assistant boss had charge of not more than two headings, he could give the work better attention, advise, or better still, supervise the setting of timber; and, at the same time, increase the output of coal from his entries, by looking after the loading of the coal and seeing that the driver is not delayed by cars not being ready. In many cases, the rule has worked well, that a man loses his "turn" if his coal is not loaded and ready for the driver when he calls.

The extra cost of such closer inspection would, in most cases, be offset by the increased output of the mines, to say nothing of the reduction in the number of fatal accidents and the delays incident thereto. By giving his entire time to the men under his charge, each assistant boss becomes more familiar with the habits of his men and is better able to expedite the work in many ways.

Safety First on the Man-Trip

By Ralph W. Mayer†

A half-inch cable carried around the man-trip of cars, and having each end fastened to the main haulage rope, serves to minimize the dangers of the trip breaking in two and the men being dashed to pieces at the bottom of the slope.

When ready to put the cable in place, it is carried, tied in a neat coil, to the back end of the trip of cars. Two men each take an end of the cable and walk toward the forward end of the trip, one of them on each side of the cars. Hooks are fastened on the ends of the cable, and these are hooked into the short length of chain on the end of the main haulage rope.

A half-inch cable, one end on each side of the cars, is strong enough to hold a broken trip, and light enough to be handled easily. The last couple of cars should be pushed together, so that their couplings are slack when the cable is put in place. This makes the cable taut, while at the same time all the pull is upon the car couplings. If the couplings should break, there would be very little or no slack between the end of the last car and the cable.

The cable is held in position by hooks made from one-fourth inch round iron. These are made about 14 in. long and have a hook on each end, both being bent toward the car to avoid catching anything when the cars are in motion. One end of the hook is hung over the top of the side of the car, and the cable hung on the other end of the hook.

If the cars have boxes or bodies overhanging the wheels, the hooks should be made long enough so that the lower end reaches below the overhanging part of the box, as it is then more out of the way. Two hooks for each car, one on each side, are sufficient.

When the men are all hoisted or lowered, the cable is taken off and neatly tied in a coil. The hooks are hung over the top of a nail keg—on the inside of the keg—and everything is in order when required for use again.

Allowing no person to get on or off the man-trip after it has started, or before it has stopped, helps to decrease the danger of accident. Disciplining anyone who disobeys this regulation by compelling him to take a day's layoff from work will soon cause it to be respected.

*Bolivar, Penn.
†Roslyn, Washington.

Superfluous Legislation

A report from West Virginia calls attention to the fact that during 1913 more than fifty bills prejudicial to the coal companies were introduced in the legislature of that state. Not all of these measures were passed, but a sufficient number became law to greatly hamper the progress of the mining industry in that particular field.

Reform legislation is now the chief bugaboo of the coal-mining men. Practically every new law that is passed means an added expense to the cost of operation. Some remedial legislation here and there has been called for; but there has been no necessity for our lawmakers running amuck. The need of the hour is the strict enforcement of present laws rather than the enactment of new ones.

BY THE WAY

A disease known is half cured.

The meteor fallen to the earth is but a stone.

Let's hope the "rule of reason" is applied in Ohio.

Do not give your measure to anyone but your tailor.

True merit is like a river; the deeper it is the less noise it makes.

A man often admits that his memory is at fault, but never his judgment.

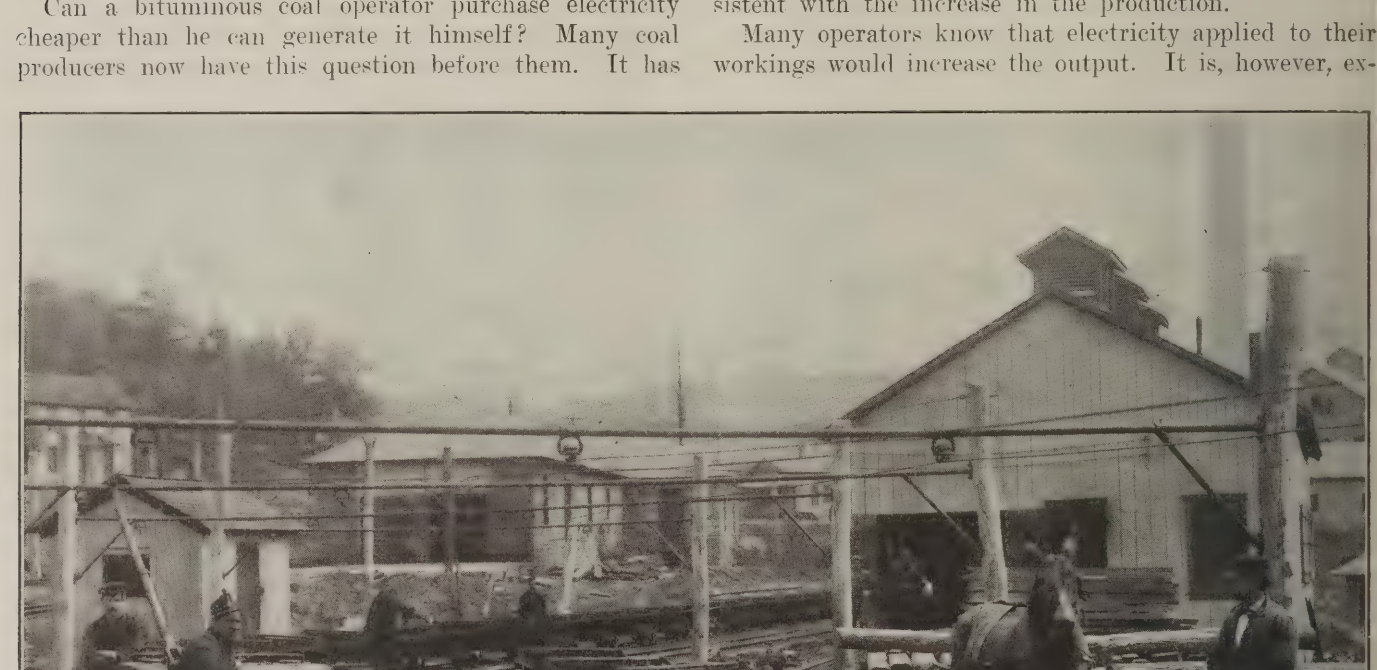
The miners are so busily engaged in determining the "booze fighting" propensities of Sam Gompers that they may not get around to asking for the customary advance. Who should worry?

Purchased Power and Bituminous Coal Mining

By A. E. Rickards*

SYNOPSIS—There has been during the past five years a vast increase in the amount of central station power purchased by coal producers. The principal uses and advantages of this source of power to the operator are here discussed.

Can a bituminous coal operator purchase electricity cheaper than he can generate it himself? Many coal producers now have this question before them. It has been created through the activities of the power companies in their endeavor to sell their product in the coal fields.



The total amount of current now purchased by the bituminous operators from central stations is estimated to exceed 100,000 hp. The income from this market to the power companies is approximately $3,250,000 per year. When one considers that the greater part of this business was obtained during the past five years, it shows a remarkable growth—there must be a reason for this expansion.

Purchased power offers so many advantages to the majority of the bituminous coal operators that it will only be a question of time when many, possibly most of them, will use it. However, before this is brought about, more must be known of its merits. Today, most of the operators know as little about what central station service affords as the power companies know about coal mining.

The situation before the average coal producer is such that purchased power supplies a means to assist in solving some of his most difficult problems. These are:

1. How to increase the production.
2. How to reduce the cost of mining.
3. How to keep the increase in the investment consistent with the increase in the production.

Many operators know that electricity applied to their workings would increase the output. It is, however, expensive to install a generating plant and equip a mine for electrical operation.

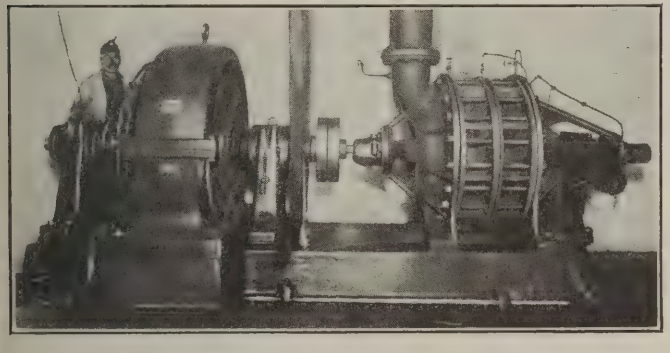
The New and the Old Method of Mine Haulage

An operation now using steam power and mule haulage can change to electric power at a minimum of expense if the current is purchased from a power company. By so doing, the greatest item of expense (the power plant) is eliminated. In this manner the tonnage can be raised with but a small increase in the capital account.

More power is required per ton of coal mined as the underground workings are extended. With an isolated plant, this increase in the demand for power frequently requires expensive alterations and additions to the generating equipment. When central station service is used additional power can be had and usually the only expense is for a new motor or motor-generator set.

The cost of power in a coal mine is an important item. A reduction in this expense means much towards lessening the cost of production. In most cases an operator can purchase electricity cheaper than he can produce it himself.

*General manager, Industrial Engineering Co., Pittsburgh, Penn.



The Present Situation

The general situation confronting the coal producers is such that in the future many of them must take advantage of purchased power. It is the one means of meeting the conditions.

Today the power required by the average mine is three times greater than the amount necessary 10 years ago. Such an increase to isolated power plants is exceedingly expensive. In the same period of time the capital necessary has increased three fold.

During the past decade the demand for coal has doubled. If the present rate of increase continues, the quantity mined this decade will be twice that mined in the one just past.

With the rapid increase in the demand for coal, the cost to produce it has become greater. If central station power will be a means to increase the tonnage, reduce production costs, and allow extensions to be made at a minimum of expense, surely the operators will want

A Motor-Driven Centrifugal Pump

it. The idea of an isolated plant is, however, so firmly rooted in the average operator's mind, that he must first be taught the possibilities of purchased power.

Now comes the question of how purchased power may be advantageously applied. It may be employed to operate pumps, fans, hoists, haulage and gathering locomotives, gathering reels, coal-cutting machines and punchers.

A general plan cannot be laid down that would apply to the electrification of all mines. Each operation presents a problem in itself and must be treated as necessary to cover its own peculiar conditions. However, the following is a general outline of applications most commonly used.

Small pumps are usually driven by 250- or 550-volt, direct-current motors. The power supply is taken from the nearest trolley or cutting line. Large pumps, in many cases, are operated only at night and are driven by 2300-volt, alternating-current motors.

Fans operate continuously and are often driven by 2300-volt, alternating-current motors. The principal advantage of this application for large pumps and fans is because it allows the use of a smaller motor-generator set, the losses incurred in converting alternating to direct current being thus lessened. Furthermore, the cost of installation is less.

The haulage and gathering locomotives, gathering reels, coal-cutting machines and punchers are driven by either 250- or 550-volt, direct-current motors.

Before describing the different kinds of machines, it would be interesting to note the methods used years ago.

Former Methods of Mining

The methods used in the early days to mine coal were indeed primitive. The operation generally consisted of digging a hole in the side of a hill at the outcrop. The coal was undermined with a pick, forced down with wedges, and then loaded into small cars running upon wooden rails. After the cars were loaded, they were pushed out to the surface by hand.

As the distance from the surface became greater, the work of pushing the cars in and out became quite burdensome and the mule was initiated into the mysterious underground haulage. This faithful animal has become so firmly rooted in this occupation that it will be some time before he has become completely supplanted by more economical methods of underground transportation.

The first power required in the early operations was for the pumps. Unless the entries could be so driven that

Mine Fan Altered from Steam to Electric Drive

the mine was self-draining, more or less water would accumulate in the workings, which had to be pumped out to keep the mine in operation.

This was at first and is still, largely accomplished by steam pumps, mostly of the reciprocating type. The steam is generated in a boiler plant, located near the pit mouth and carried underground to the pumps. These steam lines are frequently of considerable length. In the hard-coal region it is a common experience to see a steam line carried over the surface of the ground for several thousand feet from the boiler plant and then conducted down a bore hole several hundred feet deep to a pump in a mine. Only poor economy can be obtained under such conditions due to the large amount of condensation, drop in steam pressure and leaks.

The reciprocating type of pump taking steam full stroke is also inherently uneconomical. Tests upon these machines often show that they consume 120 to 130 lb. of steam per horsepower hour.

Compressed air is also used to a large extent in operating pumps. The disadvantage of this system is that it requires considerable compressor capacity; also it is not as economical as the steam pump, although it has the advantage of no condensation.

In the better class of mines, the steam and air pumps are being replaced by electric-driven pumps, thus effecting a considerable saving in upkeep and in the power consumption. The losses in electric systems are comparatively low; while the maintenance can be kept low with but little attention.

For small pumps up to 25-hp., direct-current motors

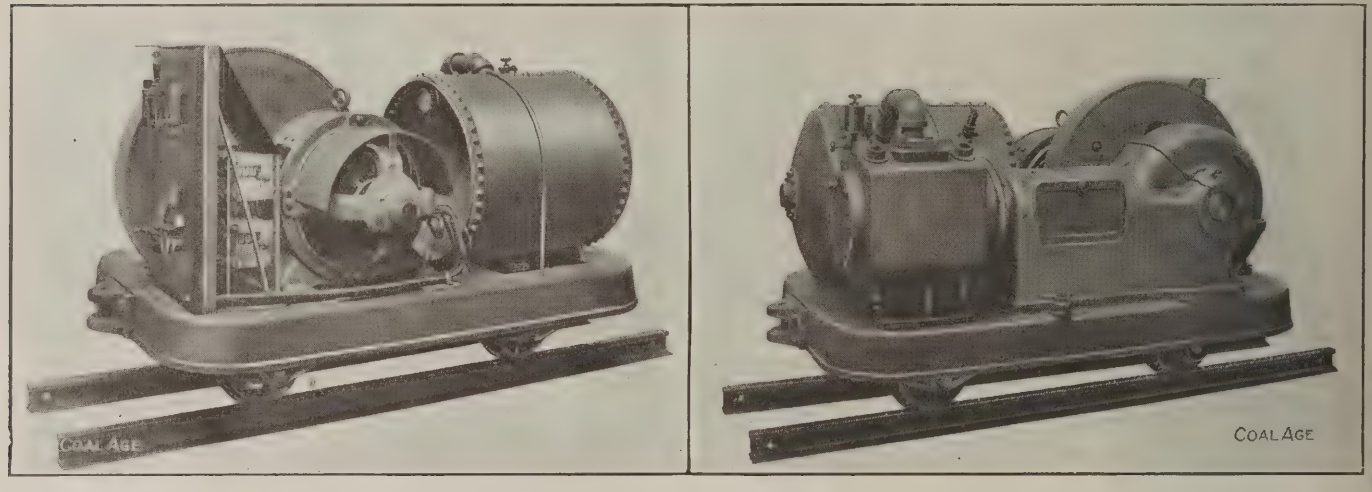
geared to duplex or triplex machines, are generally used, because the power for driving is usually taken from the haulage or the cutting lines. These motors are often arranged for self-starting and require little attention. The larger pumps are generally of the centrifugal type and it is the common practice to drive them with alternating-current motors.

The practice in some of the large mines is to operate several small reciprocating pumps throughout the mine during the day, pumping into a common sump, which is emptied at night by one or more large centrifugal pumps. This arrangement improves the load factor to a considerable extent.

Ventilating Systems

The next department about the mine to require power is the ventilating system. In the early days the operators depended entirely upon the natural draft or furnaces. A forced or induced draft, produced by a power-driven fan, has become the most reliable method of ventilation. A large percentage of these fans are driven by steam engines. However, the steam lines are often long and frequently uncovered, so that the heat losses are high.

Owing to the importance of the fan operation any new method of drive must prove itself reliable before a mine operator will consent to use it. The electric motor has proven itself thoroughly dependable when applied to a mine fan. It has many advantages over the steam engine as it requires less attention, less repairs, consumes less power and the continuity of operation is more assured.



In applying an electric motor to a mine fan, it is seldom possible to use a direct connection, owing to the inherent low speed of the fan. Belting, gears and chain drives are the methods generally used. Belting is the most satisfactory when the reduction is not too great.

Both alternating- and direct-current motors are used to drive the fans, the advantages being with an a.c. motor when purchasing electricity, as no conversion of power is necessary. Furthermore, with this arrangement, the direct-current power equipment can be shut down during a portion of the 24 hours.

In some mines the fans are operated at the same speed, 24 hours per day, while in others, they are run full speed during the day and at one-half speed during the night, on Sundays and holidays. In this way considerable power can be saved. The methods to be used depend upon the locality.

When direct-current motors are used for this work they are usually of the shunt type. By using commutating poles a considerable variation in speed can be obtained by field control with high economy.

The squirrel-cage type of a.c. motor is best adapted for driving fans at constant speed. When two speeds are desired, a double-winding squirrel-cage motor is used. If a variation in speed is required, a wound secondary motor must be employed with resistance inserted in the secondary circuit to reduce the speed. With this application the economy at slow speed is, of course, low, but as the power to drive a fan varies approximately as the cube of the speed, the actual power lost is not large at greatly reduced speeds.

Two Views of a Portable Motor-Driven Air Compressor

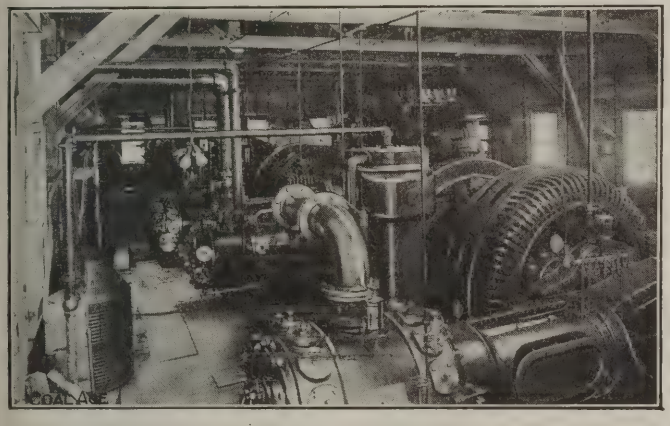
There are a number of schemes being tried out in Europe by which variable speeds can be obtained at fairly high efficiencies. This is accomplished by using a wound-rotor, alternating-current motor in combination with two or three auxiliary machines and a rather complicated control system. While these systems are meeting with a fair degree of success in Europe, where high-class labor is easily obtainable, it is rather doubtful just what results would be obtained here where skilled labor is difficult to secure in the mining field.

The motor and control for a mine fan should be as simple and reliable as possible. A properly installed motor-driven fan will operate over long periods of time with practically no attention outside an occasional inspection. Recently, many fans, formerly driven by steam engines, have been changed to motor application.

Means and Methods of Haulage

When a mine became developed and the length of the haul increased, it soon became evident that some mechanical method must supersede animal haulage. As the length of the haul becomes greater the expense increases rapidly. Rope haulage was first tried, the rope being driven by a steam engine. There are many conditions today where this means proves the best system of haulage.

For the majority of conditions, however, the electric



locomotive has proven the most economical and efficient method for both haulage and gathering. Our old friend the mule has been driven from the main gangway for some time and is now making his last stand in gathering.

The life of a mule underground will not average over four years. The cost for feed, harness, veterinary services and stabling will run about 50c. per day. Adding the wages of drivers to this it is not a difficult matter to show a considerable saving by the use of locomotives.

In extremely gaseous mines, compressed-air locomotives are used to advantage. This type of machine should be employed only when it is impossible to use the trolley type. Its cost of operation and upkeep is comparatively high.

The storage-battery locomotive, when properly constructed and equipped, will probably be the solution for the gaseous mine. At present its high first cost is a little discouraging.

As the mine haulage is in many respects similar to a railway system, the electric locomotive is equipped with

A Motor-Driven Compressor Plant

the same type of motor and control. In this country, direct current at 250 or 550 volts is the universal practice.

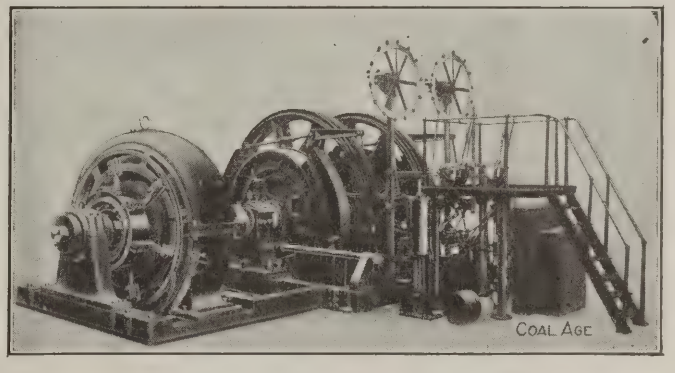
The motors are series wound and in the later types they are equipped with commutating poles which greatly increase the reliability of the machine. This feature, to a large degree, also cuts down the motor repairs and consequent delays.

The controller is of the drum type arranged for series and parallel operation.

Most locomotives are equipped with two motors, although three are sometimes used on large sizes. Where a heavier locomotive is required than the rails can carry, two machines are coupled together and operated in tandem from one controller.

Gasoline locomotives are being tried out for mine haulage, but so far have met with indifferent success.

For gathering service two types of reels are used for drawing the cars from the rooms to which the trolley wires have not been extended. The cable-reel attachment consists of a single or double conductor cable, wound upon a small drum and so arranged that a tension is kept on the cable at all times. This conductor supplies power to the locomotive and unwinds and winds up as the machine moves in or out of a room.



The traction-reel or crab, consists of a small motor-driven winch mounted on one side of the locomotive and is employed to haul cars out of rooms where it is not convenient to use an electric cable reel. This type of machine is best suited to mines where the rooms are worked to the dip and the grades are too severe for locomotive haulage.

For gathering, service locomotives ranging from 3½ to 8 tons are used, while for main haulage, the weights run from 6 to 20 tons, or even higher.

Rope Haulage and Hoists

The rope-haulage systems, previously spoken of, are used on grades ranging from 0 to 90°. In practically all cases these were first operated by steam, although quite a number of gravity systems are in use. Where power is purchased or the hoisting outfit is located some distance from the steam plant, an electric motor may be substituted to advantage A large number of steam haulage systems and hoists have recently been changed to electric drive. For small hoists and haulages, both alternating- and direct-current motors are used, depending on local conditions and the kind of power available.

For large haulage units or hoists of slow or medium speed, the alternating-current, polyphase, wound-rotor

A Motor-Driven Reel Mine Hoist

motor is used with a liquid or magnetic controller. For large high-speed hoists, a separately excited direct-current motor is used taking power from a special motor-generator set and operating upon either the Ward-Leonard or the Illgner systems.

The Actual Process of Mining

The actual operation of mining consists in undercutting the coal at the floor and then shooting it down with light charges of powder placed in holes drilled between the under-cut and the roof.

As previously stated, in the early days before the use of powder became the practice, the coal was wedged down. This was a slow and very tedious process. The undermining was first accomplished by hand with the ordinary mine pick. In fact today a large part of the coal is obtained by pick mining.

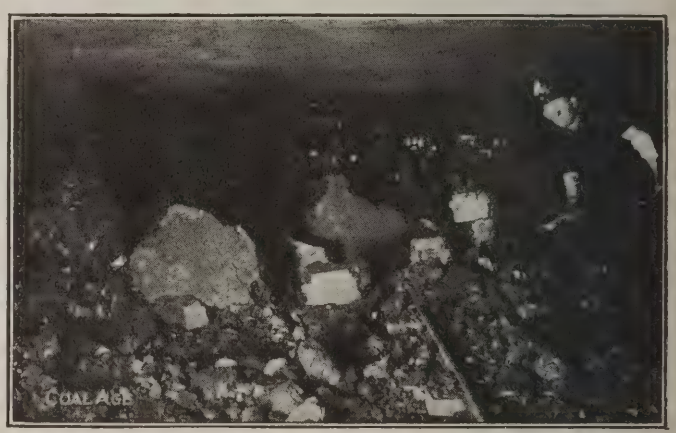
Among the simplest mechanical means for under-cutting the coal is the compressed-air puncher. It consists of a reciprocating chisel or pick, driven by air. The operator directs the blows of the puncher against the coal and an assistant shovels back the fine material produced, so as to leave a clear opening. This under-cut is about 16 in. high in front and 4 in. high at the rear and is from 4 to 5 ft. in depth. This wedge-shaped cut greatly assists in bringing the coal down with light powder charges without breaking it up too fine.

The compressor plant to furnish air for these machines,

A Chain Coal Cutter at Work and Being Moved

is usually located outside the mine near the boiler house. Electric-driven compressors may, however, be operated very successfully with purchased power. They furnish a steady load for synchronous motors, which in turn can be used for power-factor correction. Whenever possible, electric drive should be used because of the inefficiency of the compressed-air system.

Portable compressor plants are sometimes used to help out the main plant and keep up the pressure at the far end of some of the pipelines. Such an outfit is illustrated in the accompanying photographs.



A combined electric and air puncher is in use which gives the advantage of electric transmission and the puncher under-cut. This really can be classed as an electric cutter giving a wedge-shaped under-cut which is not obtained with a chain machine.

A number of straight electric-mining machines are on the market and consist of a moving chain upon which is mounted a series of small picks or chisels. These machines make an under-cut of uniform thickness from 4 to 6 in. in height and 6 to 6½ ft. deep.

The short-wall type of chain machine will cut into the face of the coal and then move across a 25-ft. room in about 10 minutes. An air puncher will require about 30 minutes to do the same work. It is largely due to machines of the former type that the immense coal production of today is possible. The present labor supply would be far from adequate if all coal were mined by the hand-pick method.

One of the illustrations shows a chain machine making a cut across the face of a room. Another shows the same machine loaded on a truck ready to move to another place under its own power, while still another figure shows the results of blasting down the coal after having been undercut.

The chain cutting machines are generally equipped with a 30-hp. direct-current compound-wound motor of 250 or 550 volts. Recently some of these machines have been driven successfully by alternating-current, squirrel-cage motors.

Result of a Shot after Undercutting

Undercutting with Air Puncher

Driving Auxiliaries and Lighting

There is often a considerable amount of power in use on the outside at a mine. This power consists principally of auxiliary hoists, chain haulages, crushers, shakers, elevators, washers, pumps, machine shops, etc. In many cases, these auxiliaries are driven by individual steam engines whose principal virtue is that they give fairly high continuity of operation. Most such applications can be easily taken care of in a much better and more economical way by substituting electric motors for the steam engines. In many cases, alternating-current motors can be applied, which greatly simplifies the power system.

In mines not using electric power, no attempt is made to light the workings. It has been found, however, that some illumination is necessary at switches, cross-overs, partings, pumps and underground fans. The incandescent electric lamp has proven the best and cheapest method of providing underground illumination.

Conclusions

A great many mines do not use electricity at all. Of ose who have changed over from steam to electricity, has been their experience that a great saving has been ected and the output increased. Of course, after a ne has been changed over, the operating forces will re- ire some time to adjust themselves to the new condi- ns.

The saving and increase in the output by the use of ctric power make themselves most manifest when cur- nt is purchased from a central station. The "invest- nt" and the "worry and care" of a substation are much s than that of an isolated plant. This is true to such an tent, that an operator once using purchased power will rely, if ever, consider going back to his own power nt.

It is not an uncommon thing, when investigating the nditions, at a mine with an isolated plant, to find that the power generated per ton of output, is as high as 12 to 14 kw.-hr., with a corresponding cost running from 15 to 25c. per ton. With the intelligent use of purchased power, the consumption should not average higher than 2 to 5 kw.-hr. per ton and the total cost for power should not run above 3 to 7c. per ton of output.

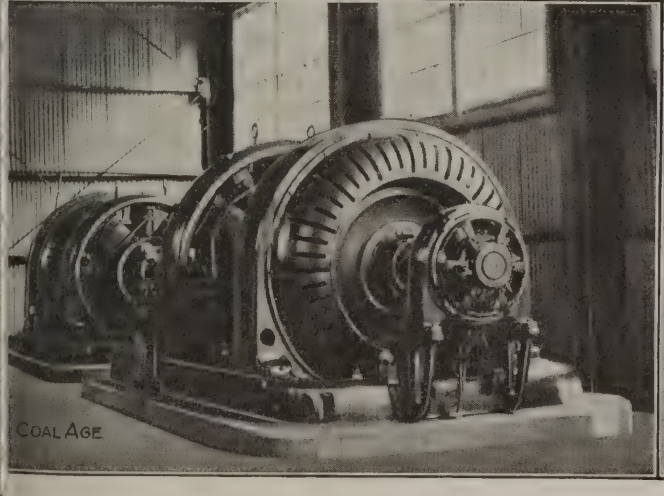
In changing over to central station power the greatest care should be exercised in selecting the proper power system and equipment. An improper selection may increase the costs instead of decreasing them.

The purchase of power is rapidly gaining ground, as is evident by the large number of mines now operated in this manner in Pennsylvania, Ohio, West Virginia, Illinois and Alabama.

The all-electric drive and purchased power are rapidly coming into favor. It will only be a few years when it will be the exception for a mine to operate from steam power generated at its own plant.

Hydro-Electric Power for West Virginia Collieries

By C. A. Tupper*



NOPSIS—A description of the generating and distribution system of the Appalachian Power Co. furnishing ctric energy to many mining operations in the Pocaontas and adjoining fields.

Projects for bringing hydro-electric power into the ocahontas coal fields of West Virginia and those closely ntified with them, such as the Tug River, Thacker, nova and Clinch Valley districts, have long been under nsideration; but the initial expense of any undertaking sufficient magnitude to accomplish the objects sought s, until recently, prevented the carrying out of such nemies.

During the past year, however, the first two of a series large water-power developments, with the necessary nerating, transmission and distributing systems, have been carried to successful completion by the Appalachian Power Co., of Bluefield, W. Va., and upward of 40 separate coal-mining operations in the Pocahontas and adjacent fields are now being served with electric energy from this centralized system, which also includes steam reserve plants to insure an uninterrupted supply of power in any emergency.

In order to secure water power of sufficient capacity it was found necessary to go nearly 60 miles to the southeast into the state of Virginia, where surveys showed that the best opportunity for a large, constant supply of hydraulic energy was afforded by the New River. This stream, which rises in the Blue Ridge Mountains, flows in a general northerly or northwesterly direction to its confluence with the Ohio. In a distance of about 30 miles through Carroll and Pulaski Counties, Va., it has a fall of 225 ft., capable of being completely utilized in four or more power sites.

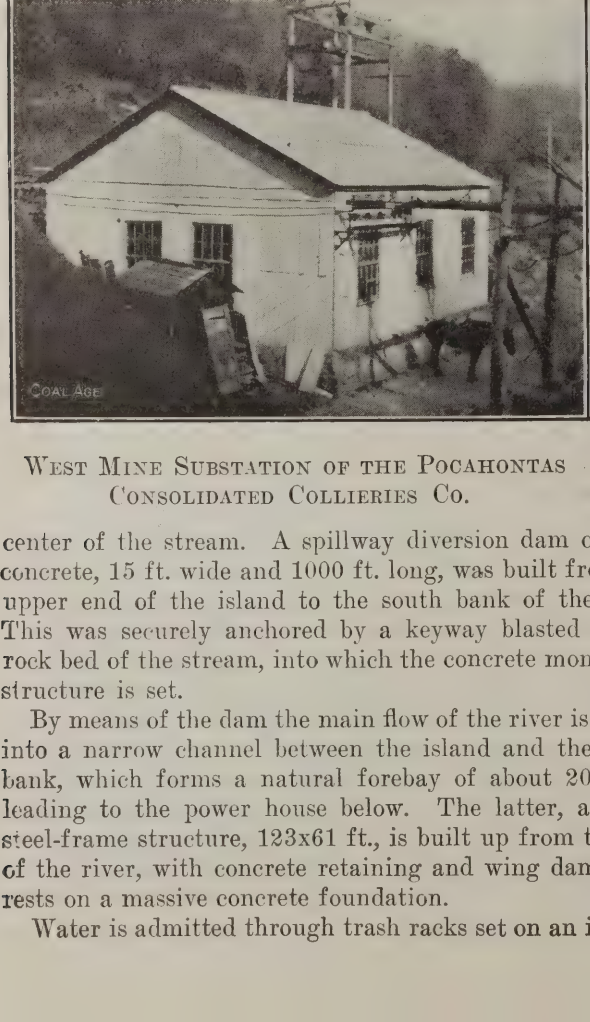
otor-Generator Sets Furnishing Direct Current for Cutting, Etc.

Interior of Hydro-Electric Plant—20,000 Hp. Installed

A Motor-Driven Air Compressor in the Pocahontas Field

Substation Supplying Power to Rolfe Colliery



By taking advantage of the natural flow, as indicated by the minimum of government records for many years past, a development of at least 90,000 hp. is possible, and this can be largely increased by the creation of two storage reservoirs in the upper reaches of the river. Furthermore, the entire drainage basin is heavily timbered, insuring a comparatively even, constant run-off during all seasons of the year; and this is one of the most important advantages of the location both to the power company and to the collieries which it serves.

Of the four power sites already selected, it was deemed advisable to undertake the development of No. 2 and No. 4 first. In constructing the headwork for station No. 4, advantage was taken of a long, narrow island in the center of the stream. A spillway diversion dam of solid concrete, 15 ft. wide and 1000 ft. long, was built from the upper end of the island to the south bank of the river. This was securely anchored by a keyway blasted in the rock bed of the stream, into which the concrete monolithic structure is set.

By means of the dam the main flow of the river is forced into a narrow channel between the island and the north bank, which forms a natural forebay of about 2000 ft., leading to the power house below. The latter, a brick, steel-frame structure, 123x61 ft., is built up from the bed of the river, with concrete retaining and wing dams, and rests on a massive concrete foundation.

Water is admitted through trash racks set on an incline, which keep out floating logs or other débris, ice, etc., and thence to intakes protected by steel headgates. The latter are normally raised or lowered by mans of motors, but can be manually operated when required. The intakes, 13x21 ft., together with the wheel chambers and draft tubes, are moulded in the concrete which forms the foundation of the station. As the water issues from the hydraulic turbines, it flows down a tailrace 1800 ft. long, which has been blasted out of the rock.

The single vertical-shaft turbines, of the Francis type have each a capacity of 3000 hp. under the normal effective head of 34 ft. The speed is 97 r.p.m. Three of these units have been installed. Each turbine drives a vertical-shaft alternating-current generator of the umbrella type,

West Mine Substation of the Pocahontas Consolidated Collieries Co.

Substation Furnishing Power to Jenkinjones Mine

from the terminals of which three-phase, 60-cycle current, at 13,200 volts, is led to a double busbar switchboard system and thence to the step-up transformer station mentioned below.

The arrangement of the power plant, with the usual high-tension oil switches, control, intergrating and protective devices, circuits for local electric service, overhead traveling crane, etc., is thoroughly modern in every respect. The details, however, differ in no essential particular from those of other uptodate stations and will not be gone into here.

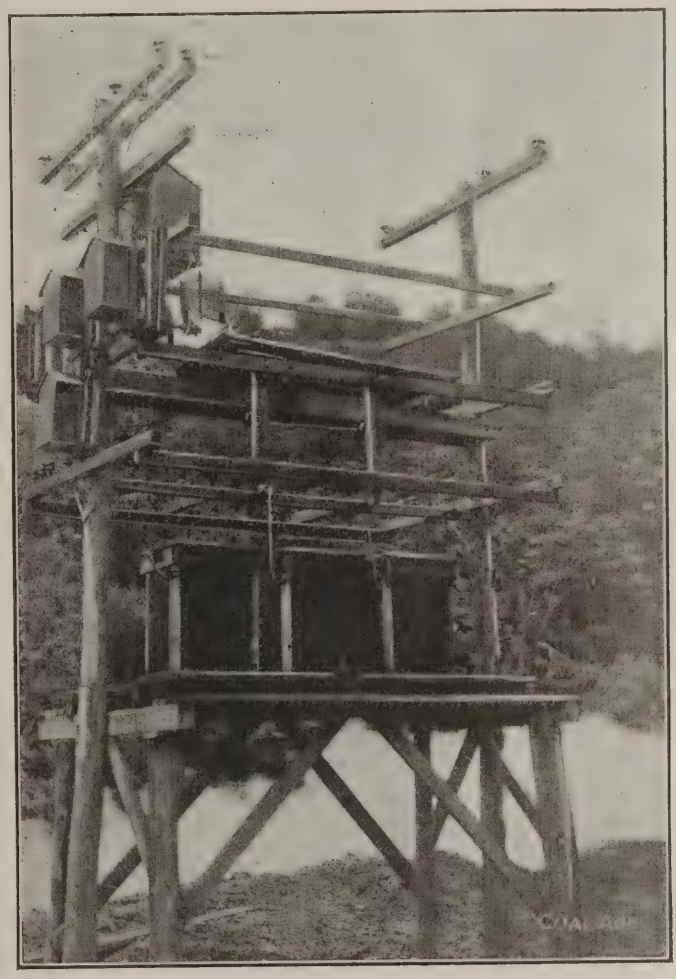
It may be said, however, that everything has been greatly simplified, avoiding the complications unduly introduced into many of the latest plants. The switch-

boards are on the generator-floor level, with most of the high-tension apparatus in a gallery just above. Excitation is furnished by two direct-current generators, which are also driven by waterwheels of suitable capacity.

In building No. 2 station advantage was taken of a narrow rock gorge, across which a solid concrete dam 504 ft. long, 56 ft. wide at the base and with an average height of 50 ft., was constructed. Between the western end of the dam and the river bank a brick, steel-frame power house, 170x50 ft., was placed on concrete foundations, with a concrete wing and core wall.

Above the power house a cut was also made for a 200-ft. overflow dam for flood times, the spillway of which discharges to a natural sluiceway formed by a depression beyond the west bank of the gorge. This sluiceway was also built up with a concrete retaining wall where necessary. The arrangement of the power house is almost identical with that of No. 4 station above described. It, however, contains four units, working under 49.5 ft. head, at 116 r.p.m., whose normal output in electric energy is 20,000 hp. There are also two waterwheel-driven exciters.

The electric current generated in both stations, at 13,200 volts, is transmitted over either section of a duplicate line system to a separate transformer station adjacent to No. 2 plant, where it is stepped up to 88,000 volts for transmission to the coal fields and other points of consumption.



The transformer house is a steel-frame brick building, 88x44 ft., containing four 6000-kv.a. units of the water-cooled, oil-insulated type. These are set in separate brick compartments, and mounted on trucks, so that they can be rolled out when required and made accessible to an overhead traveling crane. A pit is provided in which to lower any transformer for inspection and repairs. The incoming and outgoing lines are equipped with electrolytic lightning arresters and remote-control oil switches; and storage batteries guard against any failure of current for operating the latter.

The 88,000-volt transmission system consists of 237 miles of high-tension cable. There are also 165 miles of the 13,200-volt distribution lines, besides the network of wiring from the substations served by the latter to the properties of the mining companies and others using the power. All of the lines are in duplicate, to avoid any possible interruption to the service. Aluminum cables are used throughout. These are suspended from four-disk insulators upon 45-ft. chestnut poles, cut in the district, which bear oak crossarms of the wishbone type.

The system is spread out like a fan from the transformer station. There are three distinct lines radiating in different directions; and one important cross-connecting line which gives the effect of a "ring" system. What is known as "A" line runs from the main transformer station 50.3 miles through Bluefield to Switchback. "D" line runs 69.4 miles to Roanoke. "E" line extends 51 miles to Marion and Saltville. From Switchback "C" line forms a branch to Coalwood, 16.5 miles distant. "B" line connects Switchback with "D" line, via Pulaski, a distance of 50 miles.

There are seven 88,000-volt substations, and 15 of the 13,200-volt distributing stations, with nearly a hundred banks of transformers. Private telephone lines, installed on the transmission-line poles, connect the entire system; and telephones are placed in each of the 88,000-volt and 13,200-volt substations, as well as at the receiving stations of the principal collieries served with power. All load dispatching is done directly by telephone from the transformer station at Byllesby in the vicinity of the larger generating plant.

This concentration gives the system the advantage of absolute control at a single point, where one man, the load dispatcher, handles the distribution of current over all of the trunk lines, branches and feeders, so that any necessary switching combinations can be made or any part of the system isolated in cases of emergency. It is planned, when plants No. 1 and No. 3 are built, to also pass the current from them through the main transformer and control station at Byllesby, which is so laid out on the unit method that it can readily be enlarged and its equipment extended.

OPEN-AIR TRANSFORMER STATION SUPPLYING MINE MOTORS AND PUMPS

At the 13,200-volt substations, the current is stepped down in transformers to 2300 volts for distribution to the collieries and other plants using it. By means of motor-generator sets or rotary converters it can also be furnished as direct current, some of which is necessary for haulage and other purposes in and about the mines and surface plants.

The use of electric power in the Pocahontas field is nothing new, and a number of first-class steam-driven plants for the purpose have been installed; but the tendency is at present to ship out most of the coal which was formerly burned under boilers; hence the advent of hydro-

electric power, at relatively low cost, has been generally welcomed.

The question of daily expense, however, is not the controlling factor. Water power is making its way even over cheap steam power because of its reliability and is enabling mine operators to eliminate future investments in generating plants, as well as to avoid the employment of skilled engineers and station attendants, whom it has always been difficult to secure or retain, owing to the remoteness of the mines from community advantages. A much lower grade of employees can now be used for the limited service required at the receiving stations. The introduction of circuit-breakers, which automatically reset themselves after a predetermined length of interruption, is further simplifying the need of any attendance.

Formerly, also, it was often necessary to establish the isolated power plants for collieries in locations difficult of access, to which boiler feed had to be pumped against considerable heads, or where a decidedly inferior quality of water had to be used, and tube-clogging, scaling, corrosion, etc., and other similar troubles were frequent.

In contrast to all this, with a constant supply of current, equalized among a large number of consumers, there exist the material advantages of good load and power factors over the entire system, close regulation of voltage and a practically assured supply of energy under all conditions, whether during regular shift periods, overtime, shutdowns, or for momentary or prolonged peak loads. The ability to obtain any amount of power required at any time, whether much or little, becomes of particular importance in the case of machinery such as pumps which need to be kept going even when all other apparatus is idle, as well as for lighting and various intermittent or auxiliary service, which is unduly expensive when dependent upon an isolated power plant running at fractional load.

Another advantage brought about by the use of current from a central system was one that had not been anticipated, namely, the economy in power consumption and better regulation of driven apparatus consequent upon suitable speeds. To take ventilating fans, for example, it will be recognized that the running speeds were likely to vary considerably when not so intended, due to the fact that most of the fan engines were governed by throttling. When motors were installed, however, care was taken to select those of just the right characteristics, with constant or easily regulated speeds to meet the exact requirements of the service. Similar analogies can readily be followed out in the case of other classes of machinery.

A little more than 18,000 hp. is now being taken for coal-mining operations from the system above described, the heaviest user being the Pocahontas Consolidated Collieries Co., which is also the largest single operator in the fields. A. E. Gregory, of the Appalachian Power Co., with headquarters at Bluefield, W. Va., is in charge of all the arrangements for the service, which under his direction is being rapidly extended.

The engineering and construction work for the hydroelectric generating plants and entire distribution system was carried through by H. M. Byllesby & Co., of Chicago; but the present operating engineers are Velie, Blackwell & Buck, of New York City, with G. G. Wilder, Bluefield, W. Va., as manager.

The Spirit of Management

By Berton Braley

Adapted from a poem published in "American Machinist."

We've done with the days of "hit or miss"
When we blundered along in careless bliss,
In frantic hurry and foolish haste
With useless labor and senseless waste;
We've done with the days of "more or less"
When we worked by chance and we planned by guess
And we've learned there's more to a workman's job
Than putting him down where the mine's athrob,
With pumps and motors in vast array,
And letting him blindly feel his way!

For now we study and now we plan
The work and effort of every man,
The reason "Why" and the manner "How,"
To lessen the sweat of his back and brow,
Relieve his muscles of stress and strain
And lighten the task of his harried brain;
To give him leisure for rest and fun
While swelling the sum of the work that's done!

We must show the Miner the work to do,
The WAY to do it, until he KNOWS;
We must give him the mighty spirit, too,
By which the World in its wonder grows;
For the Spirit of Modern Progress comes
From men with bodies and minds kept strong,
Not puny weaklings from out the throng
Who swarm in ghettoes and fetid slums!

And so, at last, we have come to learn
That the Health of miners is our concern—
That it's our concern as Fellowmen
And brothers all, in a world that's wide,
Where we rise and fall and rise again
Like soldiers battling side by side;
And 'tis our concern in a selfish light
For men work best when they're fully fit,
With minds untroubled and calm eyes bright,
And bodily vigor and clear, keen wit!

So here's the gospel—to do our work
With little fretting or fuss or irk;
To train the toiler, wherever placed,
To labor wisely and not to waste;
To give men pride in the work they do,
To pay them well when the job is through,
And to hold their welfare and strength and health
As source and font of our truest wealth!

That's first-class gospel, because it's fair
Because it's good for the human race,
Because it moves us to do and dare
And quickens the world on its forward pace,
Because it brings us to better ways,
And so—in the long, long run—IT PAYS!

The Peruvian government has granted sundry French capitalists permission to draw up a plan for a railway starting from Sayan and terminating in the carboniferous basins of Oyon and Cheras.

Safety in West Virginia

By Frank H. Kneeland

SYNOPSIS—Some of the means employed by the United States Coal & Coke Co. to prevent accidents.

To increase the output from 100,000 tons to 400,000 tons, on the average, per each fatal accident underground, to mine over a million tons of coal without a single fatality, to operate a mine for almost two years, without a serious mishap of any kind, shipping meanwhile over 750,000

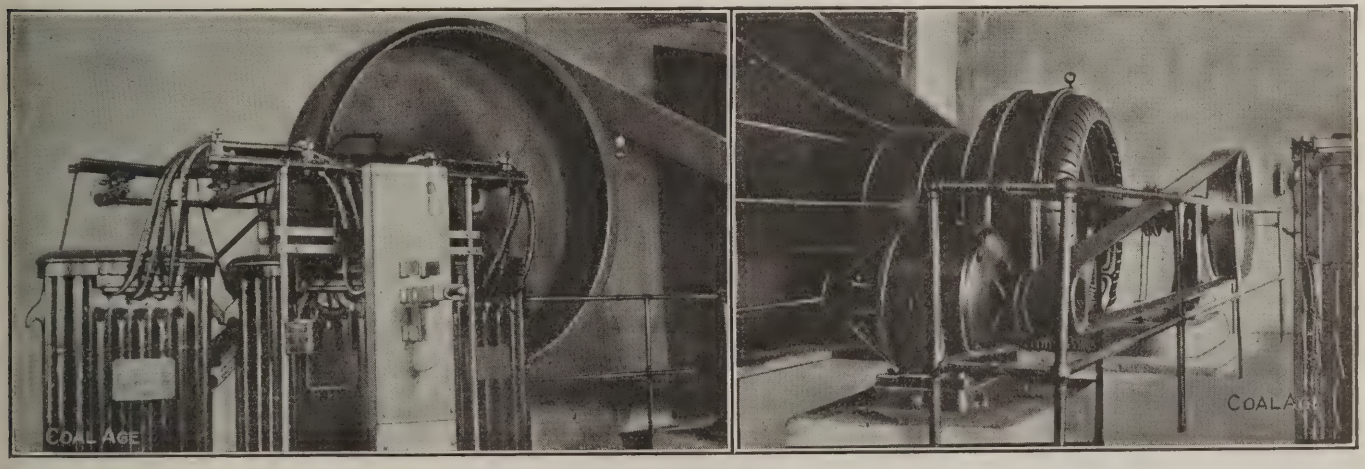
Fig. 1. A Drift, Mouth, Fan and Substation

tons of coal, to render its operations safer than the mines of either Great Britain or Belgium, and approximately one-third as hazardous as surrounding collieries, are a few of the results attributable to the campaign for safety which has been waged by the United States Coal & Coke Co., of Gary, W. Va., during the past four years.

Such progress as this, in face of the many difficulties, such as the explosibility of gas and dust and the dangers from drawslate, rash and kettle-bottoms encountered in the Pocahontas region, could only be accomplished by the exercise of painstaking care and eternal vigilance.

The accidents occurring at a coal mine may be broadly divided into two classes; namely, those which happen underground and those which transpire upon the surface. Underground, the principal danger arises from falls of roof and coal, and from electrical apparatus, such as trolley wires, machine cables, etc. Above ground, the workman's greatest peril is from machinery. The present article will deal with this latter danger and the methods employed by the above named company for its circumvention. Accidents underground will be dealt with subsequently.

Accidents occurring with machinery may be forestalled by two distinct and widely dissimilar means, neither of which is in itself inadequate. The first of these has to do with each particular piece of mechanism itself, while the second deals with the mental attitude of the workman. In other words, the two means to be employed for accident prevention with machinery may be designated as safety appliances and morale.



The end sought in the design, construction and application of safety appliances to machinery and mechanical devices, is a single one; namely, to render dangerous contact, intentional or otherwise, between the attendant's person and the moving parts of the machine impossible. The forms which devices to accomplish this end may take, however, are vertitably legion, and embrace everything from headless or hollow setscrews to elaborate guards completely incasing and insulating an entire machine from its operator.

The accompanying illustrations give an idea of some of the many devices employed by this company for this purpose and are for the most part self-explanatory.

The passenger car shown in Fig. 4 is used to haul the miners from the town of Anawalt, located in a valley, to the mine up an incline approximately 1200 ft. long. It is provided with a safety catch not shown in the drawing, controlled by a fly-ball governor, which releases two toothed jaws, gripping two auxiliary oak rails, should the speed at any time exceed a certain predetermined amount. Hand trips are also provided at either end of the car.

The automatic release is periodically tested by allowing the empty car to attain, during descent, the critical or trip speed. The same experiment is less frequently repeated when the car is loaded to its normal capacity with rock or other inanimate weight.

At the present time it is the endeavor of this company to purchase all new machinery adequately guarded, where possible. Many machines now in use were, however, on

Figs. 2 and 3. Two Views in Substation Shown in Fig. 1. Note Pipe Handrails around Machines and Belts

hand before the active campaign for safety started. For these it has been necessary to design and construct suitable guards for the dangerous parts. Various materials and types of guards have been tried from time to time, the designs being constantly improved and reduced to what might be termed standards.

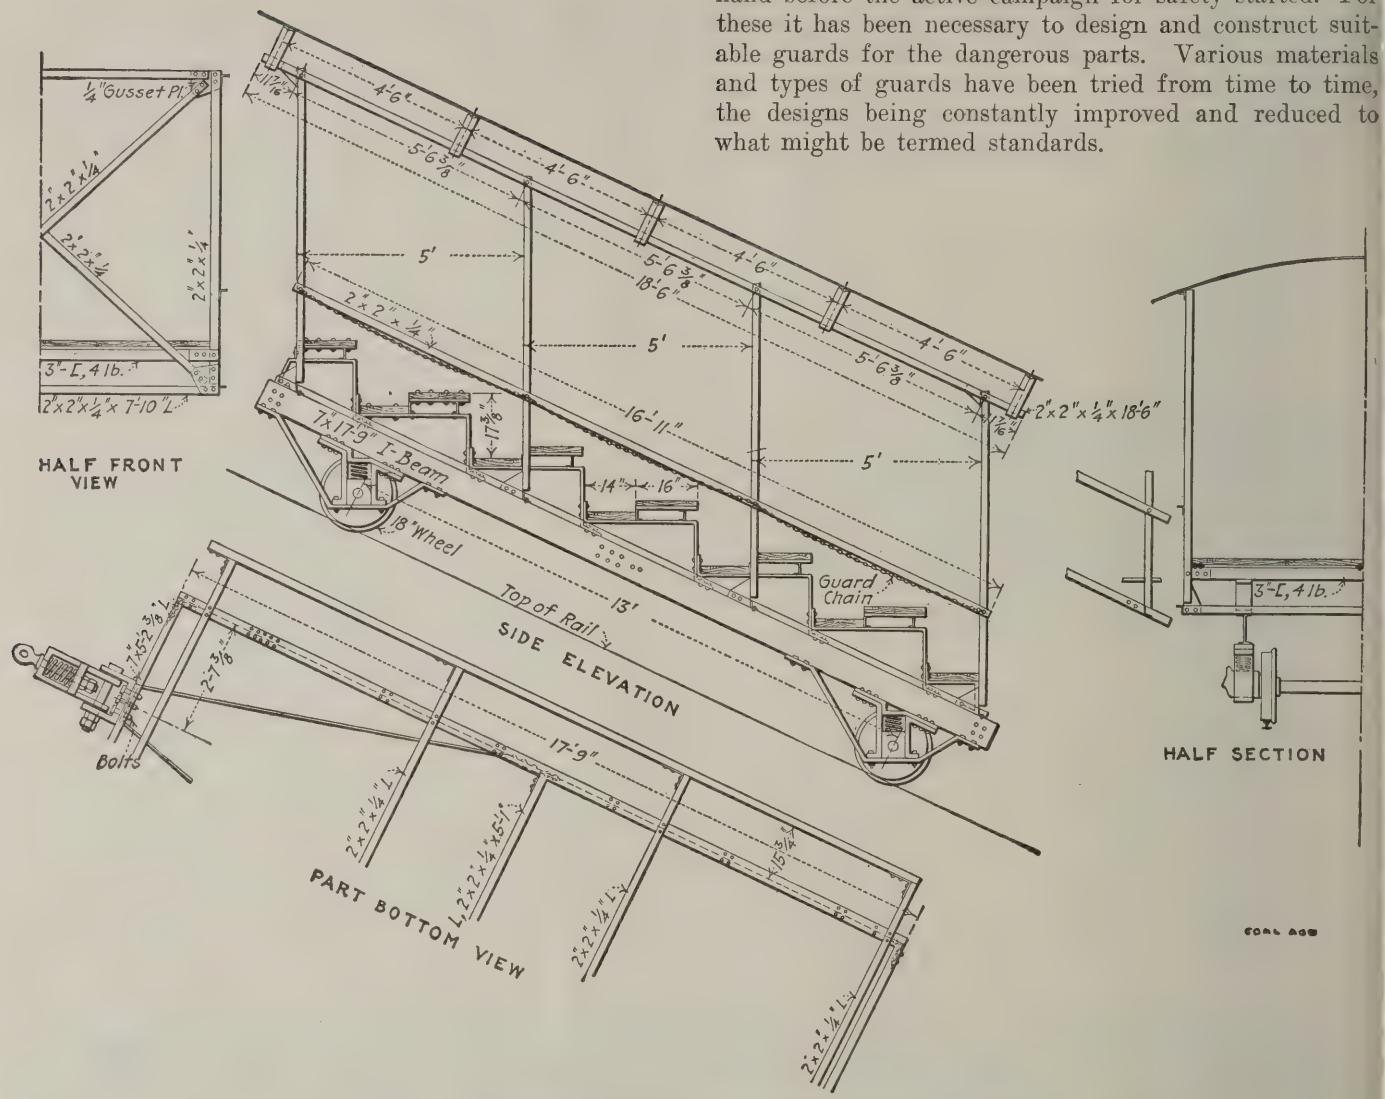


FIG. 4. INCLINE CAR FOR HAULING MINERS TO WORK

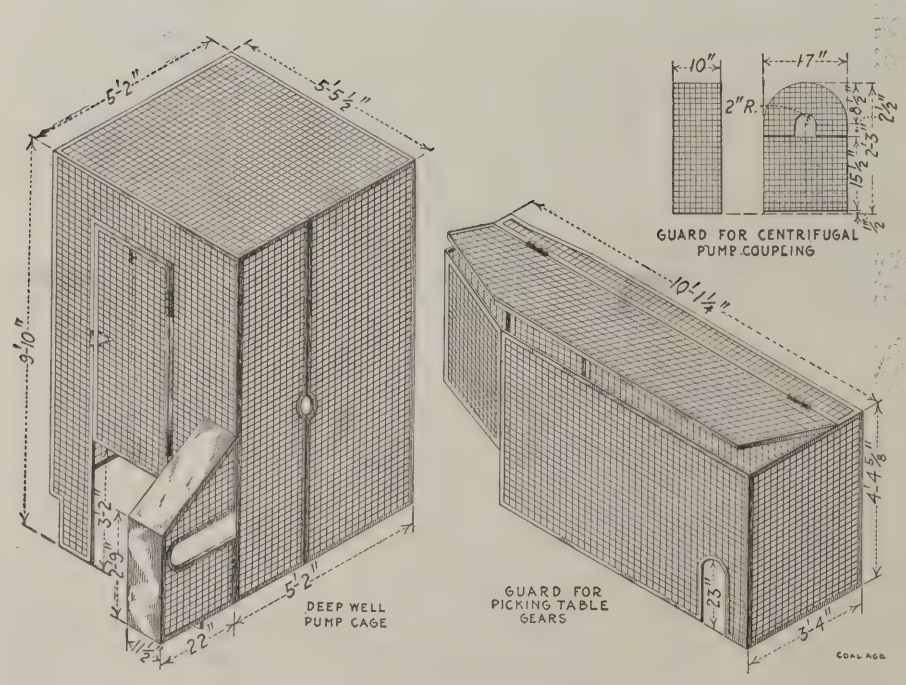

FIG. 5. GUARDS FOR A DEEP-WELL PUMP, PICKING-TABLE GEARS AND A PUMP COUPLING

Take, for example, such a dangerous piece of mechanism as the reducing gears between a picking table and its driving motor. For such places, wooden guards are both unsightly and combustible. Pipe handrails are much better, but cannot ordinarily be easily and quickly removed or returned to place in case of repairs requiring complete access to all gear parts. Sheet-iron cases are still better, but obscure the gears when in place, and have a marked tendency to chatter noisily under even slight vibration.

At the present time, heavy wire netting, carried on angle- or channel-iron frames, which may be easily unfastened from each other and thus removed, is considered standard. These guards not only absolutely prevent contact with the gears, but are neat in appearance and permit the moving parts to be at all times easily seen. Such guards are shown in Figs. 5 and 6.

For guarding pulleys and belts and many other similar pieces of mechanism, the simple pipe handrail is found very satisfactory. A few of the many applications of this type of protection may be seen in Figs. 2, 3 and 7. For protection against vertical belts, particularly in machine shops, a frame of strap iron is often employed.

rather one which is most frequently responsible for fatalities around machinery, is a revolving projection, such as a setscrew or clamp collar upon a shaft. A feather or spline, or even an open keyway, may also be the means of catching a workman's sleeve or other part of his clothing, with disastrous results.

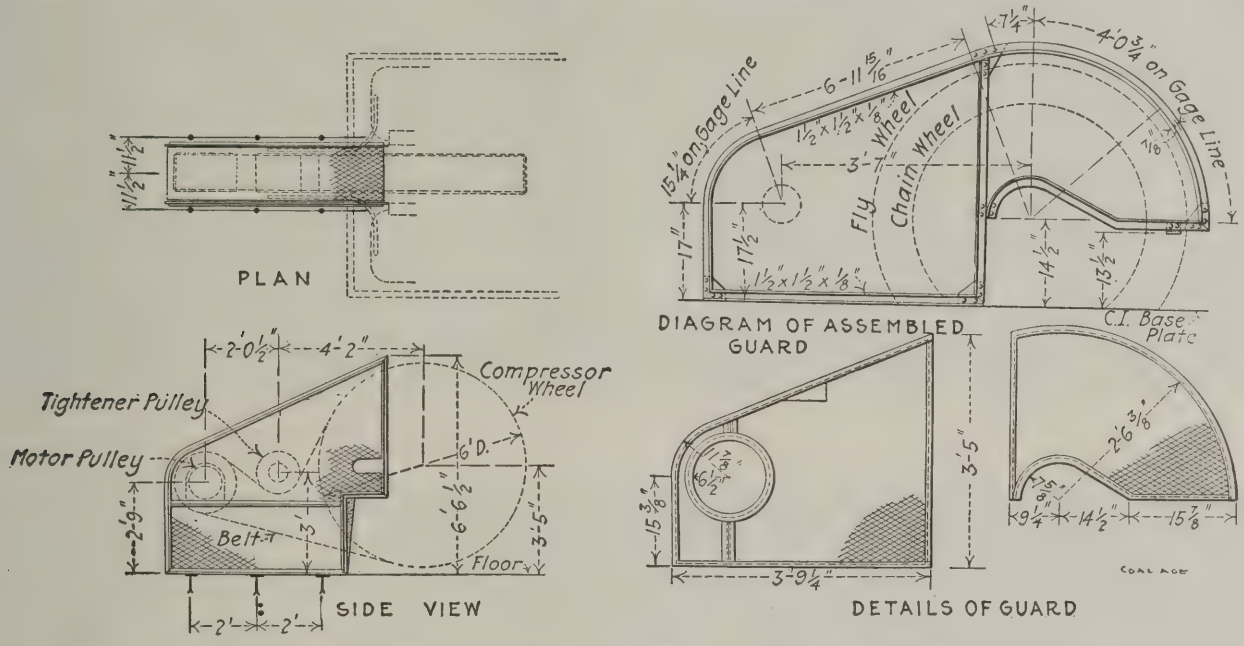

FIG. 6. TWO GUARDS FOR DRIVES TO AIR COMPRESSORS

Here, also, when a gear guard is either rigidly or movably attached to the machine, it is frequently made of a frame completely covered with sheet iron. This is not altogether objectionable where skilled labor is employed and careful inspections are regularly made. Belt and gear guards of the above named type are shown in Figs. 8, 9, 10 and 11.

One of the most dangerous pieces of mechanism, or

In the practice of this company, exposed collars must be smooth with no sharp projections. Such parts are now manufactured and sold as safety collars. Feathers which are so located as to be dangerous are guarded, and keyways similarly placed are filled up.

First-aid teams have been organized at the various mines and first-aid cabinets are conveniently located at shops, substations and tipples. These are, however, un-

welcome precautions, as the primary intention is to prevent accidents, not to take care of their effects. It is recognized, however, that some accidents will unavoidably occur, and in such cases no expense or effort is spared to quickly and effectually alleviate the suffering of the victim and render his recovery prompt and certain.

Here as elsewhere in the plants of the Steel Corporation many valuable suggestions have been received from the workmen themselves. It is freely acknowledged that the appointment of safety and works committees has done much to avert mishaps of all kinds. One great step, perhaps the greatest, toward industrial safety, has been taken

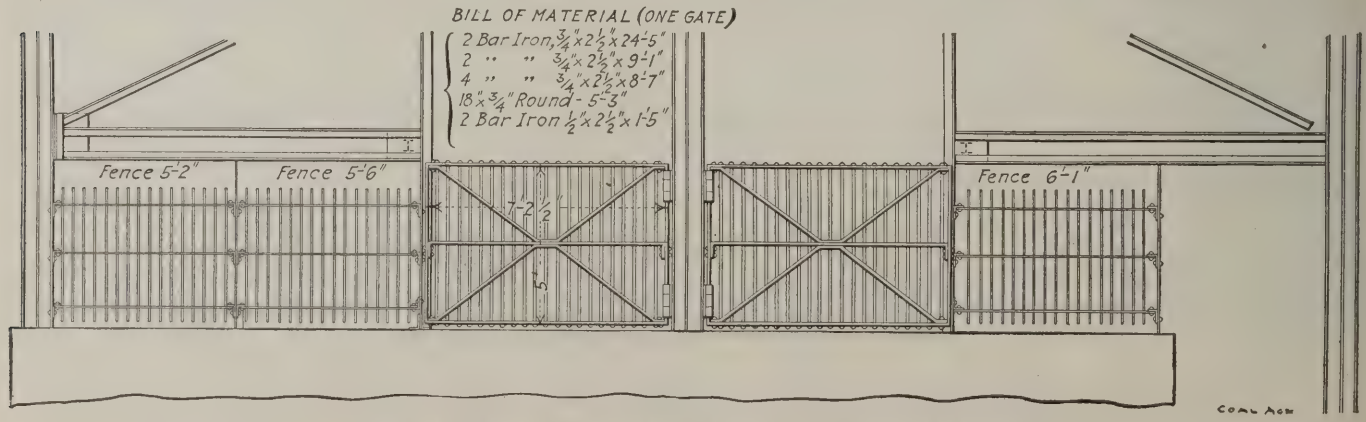

FIG. 14. IRON FENCE AND GATES AT A SHAFT MOUTH

when the workman himself becomes thoroughly alive to his own responsibility for danger and dangerous practices.

By means of danger signs, placards and illuminated safety mottoes and warnings, but still more by careful training and example, the management of the United

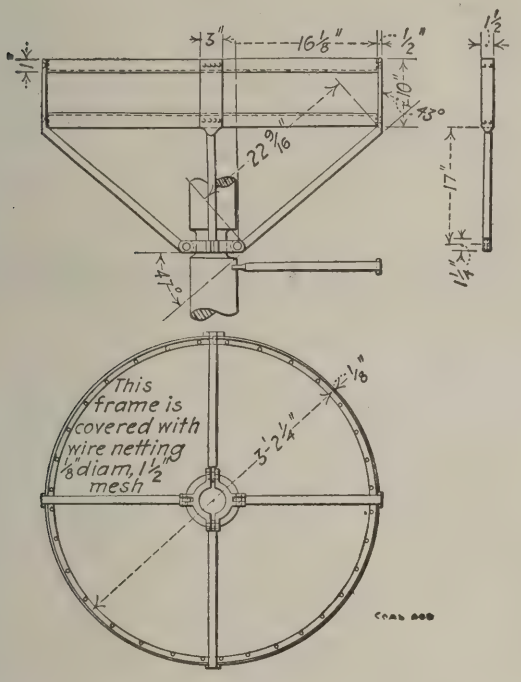

FIG. 15. GUARD FOR GOVERNOR ON CORLISS ENGINE

States Coal & Coke Co. constantly strives to bring home forcibly to every man in its employ the perils incident to his daily work, and the importance of eternal vigilance and caution in an industry as inherently dangerous as that of coal mining.

Connecting Motors to Mine Fans

BY H. J. BOOKER*

SYNOPSIS—It is frequently advantageous in mine ventilation to be able to shift the fan drive from one motor to another. Two such arrangements are here described.

The successful connection of two motors to a mine fan so that an auxiliary motor is always ready and can be brought into service without stopping ventilation is claiming the attention of a number of mine managers and mechanical engineers throughout the coal fields today. The accompanying illustrations show how the writer accomplished this result in a satisfactory manner.

Fig. 1 shows a large double-inlet reversible mine fan. The motors are so arranged that either can be disengaged when in service without shutting down. To shift from one motor to the other, it is only necessary to start the one to be used and change the clutches. This can be done without any appreciable variation in the speed of the fan.

The fan shaft is continuous; the hub of the friction-clutch pulley is fitted with brass bushings, and ample means for lubrication are provided, so that the latter may run loose on the shaft. The clutch hub is keyed to the shaft and the motors are belted to the fan as shown.

It has been found in practice that this is a much better plan than to make the fan shaft in three pieces joined together by means of clutch couplings to be thrown in or out when changing motors. The reason for this is apparent when the weight supported by the fan bearings as compared to that resting upon the clutch and pulley bearings is considered. The fan bearings naturally wear down the faster, making it impossible to keep the three segments of the shaft in line. This causes considerable bearing trouble, which necessitates frequent shutdowns.

*Monongahela, Penn.

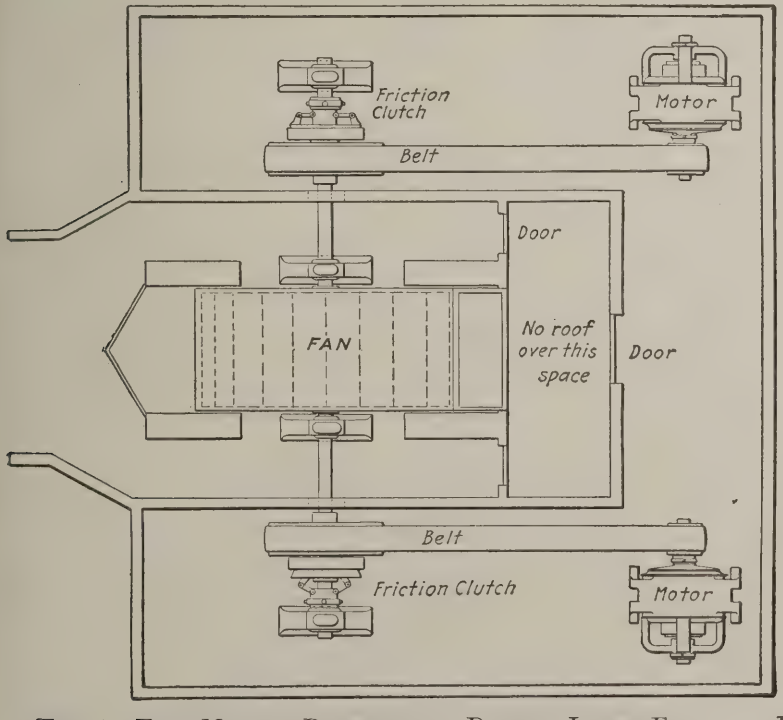

FIG. 1. TWO MOTORS BELTED TO A DOUBLE INLET FAN

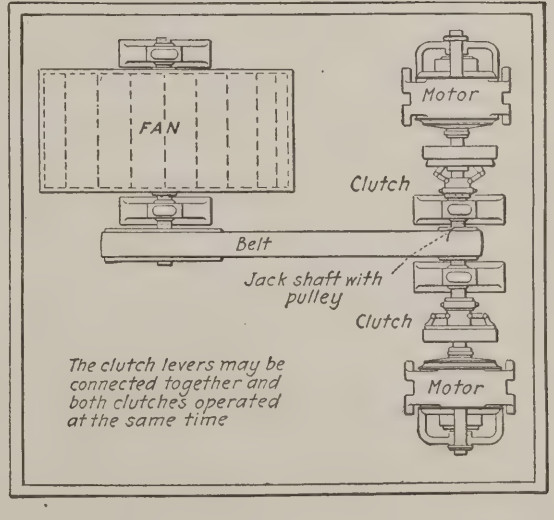

FIG. 2. MOTORS BELTED TO A SINGLE INLET FAN

Fig. 2 shows a small single-inlet mine fan to which is connected two motors, either of which is of ample power to drive it to its full capacity. In this arrangement the motors are connected to a jackshaft by friction clutches. The jackshaft carries a pulley to which the fan is belted. By this method the operator can change motors without allowing the speed of the fan to vary as both clutches may be operated simultaneously.

Method Applicable Also to Double Inlet Fan

This method may be employed to drive a double-inlet fan similar to that shown in Fig. 1, but the two-belt arrangement is preferred since if the bearings on the jackshaft give way, the fan will be out of commission and there is less danger of the large fan bearings giving trouble than those of the high-speed jackshaft.

Either of the above systems will give satisfactorily service with a reasonable amount of attention, without which no equipment can be expected to give good results.

With the arrangement of motors and shafts outlined above, three means for power transmission are available, namely, belts, ropes and silent chains. Of the three, the writer prefers a sole-leather belt, which, if properly cared for, will last several years. Ropes are satisfactory for power transmission, but do not last well. They have a way of giving out when they are most needed. One year appears to be about the average life of a rope in continuous service on a mine fan.

The Indianapolis Convention

SYNOPSIS—With only about a dollar to spend per man on a possible strike in the spring, the United Mine Workers of America was inclined to be conservative, though men were present who figured every dollar over a hundred times and found use for all. There is plenty of evidence that the direct-action element will soon replace the socialists as disturbers in the organization.

The first biennial convention of the United Mine Workers of America met at Indianapolis, Ind., on Jan. 20. In the afternoon a motion was made, but not carried, to suspend the rules so as to permit a vote to be taken on removing the convention to some other city, as a rebuke to the Chamber of Commerce and the business men for their stand in the recent teamsters' strike.

It will be remembered that Mayor S. L. Shank, of Indianapolis, was compelled to resign for his weakness during the street-car strike, and H. R. Wallace, the city comptroller succeeded him. Five hundred business men were sworn in for special service, one hundred being mounted guards. Order being restored, the strike utterly failed, and it was this strong defense of law and order which angered some of the miners' leaders.

At the morning session, Vice-President Miller of the Central Labor Union presided, and addresses of welcome were made and sergeants-at-arms and messengers appointed by President J. P. White. A resolution was passed, calling on Congress to investigate the Colorado strike, and, to present the matter more effectively, S. L. Montgomery, of Charleston, W. Va., and W. L. Farley, of Pratt City, Ala., were delegated to proceed to Washington at once with the resolution.

President White presided at the afternoon session and only business of a routine character was transacted, such as the reports of the rules committee and of the officers of the organization. The report of the president was an extremely conservative document. He has realized what a drain has been caused on the treasury by the expenditures in West Virginia, Colorado and Vancouver Island during the past year. As one has failed and the others seem about to come to a disastrous end, there is nothing to make the president buoyant. There has been continued strife and no prospect of any immediate return in dues from the sections affected.

Strike Fund Is Equal to 73c. per Union Man

Secretary-treasurer Green showed incidentally why conservatism must have the approval of the Union officials. The paid-up membership was 377,682 in December, 1913. In the past two years $2,328,167.87 has been expended for relief, and there is now a balance of $278,-032.30. This seems a fairly large war chest till it is divided by the number of members. The figure obtained by such division is 73c. When we recall the costs of the convention, and the fact that two costly strikes are underway, we can hardly anticipate a long and costly strike this spring. If such a suspension occurs, it cannot be dignified as a strike. The whole reserve fund of the organization in December, 1913, would only provide $1 for each bituminous mine-worker, for there are 277,506 of these men in the union. However, there is enough money on hand for aggressive agitation.

Craft Organization vs. Industrial Unions

The second day developed the latent struggle between industrial and craft unionism. The American Federation of Labor has been unionizing crafts. Thus, in organizing the mining industry after the Federation model, the miners would have one organization, the loaders probably another, the machine runners a fourth, and so on. But most of the unionmen today believe that this promotes strife between crafts, and certainly does not permit a united front to be presented to the mine owners. They desire to organize by industries and not by any smaller units.

The American Federation of Labor has been regarded as an aristocratic concern, anxious to uphold the craftsmen and having little interest in the unskilled workmen. The industrialist declares that when the latter is unorganized, he aids in strike-breaking whenever a dispute arises.

This accounts for Duncan McDonald, of Illinois, attacking S. P. Gompers and Thomas Kennedy, of Hazelton, Penn., declaring that almost every delegate to the Federation has been insulted. An attack on Secretary of Labor, William B. Wilson, also shows the divisions in the United Mine Workers of America.

Frank M. Ryan, of the International Association of Bridge and Structural Workers, thanked the miners for their assistance and urged that conspiracy was just as

permissible for the poor as for the rich. He did not say, however, that the conspiracy of which he was convicted was one to transport explosives illegally in connection with several bomb settings in which life was menaced.

Some Uses for That 73 Cents

On the third day the Louisville, Col., local urged that all available funds of the union be used to purchase mines, and that as funds be obtained, all the mines of the country be bought and operated by the union. Other resolutions urged that old-age pensions and a home for disabled miners be established. The Bear Creek, Mont., union wanted coöperative wholesale supply houses started under the auspices of the union. A much larger number favored the construction of an executive office for the organization and the establishment of a plant for printing the *Mine Workers' Journal.* They propose that when the strikes are at an end 50c. be collected from each member every month until $500,000 is collected.

A resolution was passed after much debate that "the time had arrived, owing to the present economic conditions and the machinations of the interests in many places, for the laboring people to come together in a political party." Several socialists were anxious to annex that approval, notably William Hynes, of Fayette City, Penn., and Preston Gunnoe, of Peytonia, W. Va., but no party was designated.

J. P. White Loses Nominating of Scale Committee

On the 23rd, the delegates took from J. P. White the nominating of the scale committee, on the ground that the officers of the organization had not "worked in the mine for a few years and did not know the working conditions like the men at the face of the coal." It was decided that the scale committee should be elected from the floor of the convention.

There followed a fierce onslaught on the making of contracts with operators. An advocate of the Industrial Workers of the World, from Virginville, W. Va., presented a resolution declaring that "fake labor leaders" with false methods were tying the miners with long-term agreements." He believed in the general strike, such as he alleged had been so successful in England.

The Opposition to Militarism

A representative from a Virginia local union located at Pocahontas was expelled from the meeting, as it was declared that the local was a spurious offshot formed by Baldwin-Felts detectives and not by real miners. Several delegates protested against the army, militia and boy scouts, and a resolution was presented opposing the enlistment of any of the members of the union in the militia and condemning the boy-scout movement.

Another resolution provided for a general strike in case of the United States engaging in war. A six-hour day so as to give work for everybody was also urged. However, the men were disposed to be conservative, and doctrines now popular in Europe received little approval.

The miners did, however, vote in favor of compelling all mine carpenters to give up their membership in the Brotherhood of Carpenters and Joiners, and W. O. Green, the secretary-treasurer, said that organization was favorable to the move.

Mostly Politics

On the 24th, the meeting passed a resolution favoring Federal mothers' pensions, old-age pensions, liability and compensation laws. The miners of East Charleroi, Penn., presented a resolution urging the discontinuance of the use of electricity underground, and the resolution was adopted in substance and referred to the different districts for settlement. Another resolution introduced importuned Congress to pass a law making it unlawful for any person, firm or corporation to import into a strike district any strike-breakers, nonunion workers, detectives, or gunmen. The same resolution called for laws prohibiting the use of state troops in strike districts.

On the 26th, the meeting settled down into the harness by passing a resolution in favor of the initiative, referendum and recall, and providing that the recall be applied to constitutional amendments and that judges be prohibited from declaring unconstitutional laws which have been passed by the people.

Much disgust was expressed that time worth $1500 was expended on solving whether the miners of Coffeen, Ill., or of Fallon in the same state should pay a doctor's bill of $74.45. James Lord was elected president of the mining department of the American Federation of Labor and put on a salary. He will be located in Washington, D. C.

Shorter Hours and Fewer Aliens

The organization passed a resolution favoring a shorter work day until all surplus labor is employed, and an enactment of law prohibiting immigration from any country till that same result is assured and a resolution requiring certificates of competency as miners of all employees who wish to work in the mine. The resolutions committee offered a resolution, which they had amended, favoring municipal employment agencies and eliminating private labor bureaus. Federal mine-safety laws were demanded in an adopted resolution.

On the 27th of January the international executive committee was empowered to appoint a committee to meet a similar body authorized by the Western Federation of Miners. These committees are to discuss amalgamation of the two unions, and if the plan is agreed on, it is to be submitted to a referendum.

The following day was wasted by Duncan McDonald, who made a severe attack on S. J. Gompers, calling him a liar, slanderer and poltroon, accusing him and the executive board of the American Federation of Labor of drunkenness. After preparing to leave, Gompers managed to reply to his critics. Later, the miners reindorsed woman suffrage, discussed a plan to reduce representation at conventions and refused to approve of the resolution excluding unionmen from the militia.

Delegation to Be Reduced

On the 31st, while alleged to be feeling quite sore at the extravagant expense ($15,000) resulting from the debate between McDonald, Moyer and Gompers, the delegates nevertheless made little progress. It was alleged that 30 interlopers had been planted by a Pittsburgh detective agency to create disorder.

The committee on resolutions advocated, however, a reduction of the delegation to conventions. They commended that one delegate be elected for every 1000 members, in all only about 383 men, instead of more than 1500 as as present. The organization voted not to permit the money of locals to be spent in aid of any strike,

unless the strike was indorsed by the American Federation of Labor, or an affiliated organization. This will bar the Industrial Workers of the World from Union support.

J. A. Holmes, director of the Bureau of Mines, and W. D. Ryan, former secretary-treasurer of the United Mine Workers, and now with the Bureau, both spoke and were well received.

On Monday, Feb. 2, the miners met at the German House, Tomlinson Hall having been previously engaged for a poultry show. The day was largely wasted over a wrangle about the auditing expenses, and the sinister causes said to be back of criticisms of the auditors.

The convention passes over to the third week without notable results. Gompers is to be credited with some judgment in saying—"Taking the newspaper reports as a criterion, the most important work this convention has done has consisted of attacks on the American Federation of Labor and its officers, and discussing whether the president's salary shall be increased $1000 a year." Nothing has been accomplished and two weeks have passed. The only things essayed are what the United Mine Workers cannot do, the regulation of street-car traffic being a case in point. It is estimated that every roll-call costs $11,000.

Decisions Expected

Apparently, there will be a demand for an increase of 10c. per ton on mine-run coal. Engineers will ask an increase of $20 a month, and firemen, blacksmiths and other topmen will demand 25c. a day more than before. A similar increase will be asked for drivers, trip riders, timbermen, track and pumpmen, motormen, trappers and other inside workers. The scale committee is also considering an increase, for all men who receive less than $2.25 a day, proportional to the raise in wage demanded by the miners. There is a proposition to advance the wage scale of all surfacemen, so as to make it equal for all employees.

The pushing of cars promises to be a vexed issue, and the workers will probably refuse to incorporate in their scale the Cleveland agreement, that nothing shall be demanded in the management of mines which will increase the cost of production.

The operators of the central competitive field, covering western Pennsylvania, Ohio, Indiana and Illinois, have been asked to meet the scale committee in joint conference at Philadelphia, Tuesday, Feb. 10. The district convention at Pittsburgh is set for the same week and must be deferred, but it is hoped that the Illinois district convention can be held on Feb. 17 as scheduled.

Proposed Law for Kentucky Coal Mines

Special Correspondence

The following proposed legislation, under the caption of House Bill No. 332, known as an Act to regulate the employment of physicians and surgeons by companies and corporations operating coal mines or lumber mills in the State of Kentucky, was introduced in the General Assembly at Frankfort, Ky., Jan. 28, by Representative W. M. Webb, of Johnson County. It reads as follows:

Section 1. That when it becomes necessary for any company or corporation owning or operating a coal mine or lumber mill in this commonwealth to employ a physician or surgeon to treat or attend the employees at said coal mine or lumber mill, in case of sickness or injury, that said physicians or surgeons shall be selected by the employees working at said coal mine or lumber mill by a majority of said employees working at said coal mine or lumber mill. That said physicians or surgeons shall be employed for a period of one year unless sooner removed or discharged by said company, upon the request of said employees, which shall be done upon petition signed by a majority of the employees employed at said coal mines or lumber mills; provided that a copy of said petition has been posted at the main entrance of each mine or at the mill of each lumber company at least ten days before it is presented to said employees for their signature. That the sum so paid each physician or surgeon shall be paid by said employees at the rate of $1 per month for married men and 50c. for single men, which amounts shall be deducted from the earnings of the employees working at said coal mines or lumber mills, and that each married man's family shall receive the services of said physicians or surgeons without any additional cost.

Section 2. Any company or corporation violating said act shall, upon conviction, be fined not less than $20 nor more than $100 for each offense.

Information Worthy of Your Most Careful Attention

During the next few weeks, the pages of Coal Age will contain the most interesting and the most valuable assortment of articles ever arranged for coal-mining men. Among other things, we will publish a paper on coke manufacture, giving a detailed comparison of beehive and byproduct ovens. Valuable figures of operating cost will be included.

Then there will be articles giving complete data on a recent mine fire, methods of measuring gob temperatures, important details in connection with the construction of colliery plants, comparison of steel and wooden tanks for coal mines, description of a new and modern mine in Alabama, design and operation of a German coal-screening plant, signaling developments in British coal mines, methods of mining in Iowa, power plants at Westphalian collieries, steel vs. wood for supporting mine roofs, approved methods of mine surveying and the syndicate system of selling coal and coke.

There are a number of other articles already on hand and of equal value to any of the foregoing. Some of Mr. Braley's best poems, alive with human interest, will be printed in early issues. Then there are the coming wage agreements which will focus the attention of mining people. Coal Age will cover all phases of this labor controversy as it has never been handled before. All the news of both factions in the contest will be published.

Errata

A. R. Tibbits, who was rightly credited with the article on the Colorado output in 1913 (Jan. 10) is not one of the inspectors of coal mines of that state, but is employed in the office of John Dalrymple, who is the chief inspector of Colorado.

In our issue of Dec. 20 we stated that the Vulcan mine, which recently was the scene of an explosion, was located at Lafayette, Boulder Co., Colorado. There are two Vulcan mines, both belonging to the Rocky Mountain Fuel Co., one at Lafayette, and one at Newcastle. The Newcastle mine was the one which exploded. This mine is operated by the Coryell Mining & Leasing Co. The confusion, therefore, was easily made as in our mining list the Rocky Mountain Fuel Co. had only one Vulcan mine, that at Lafayette. The coal at Newcastle is bituminous not lignitic.

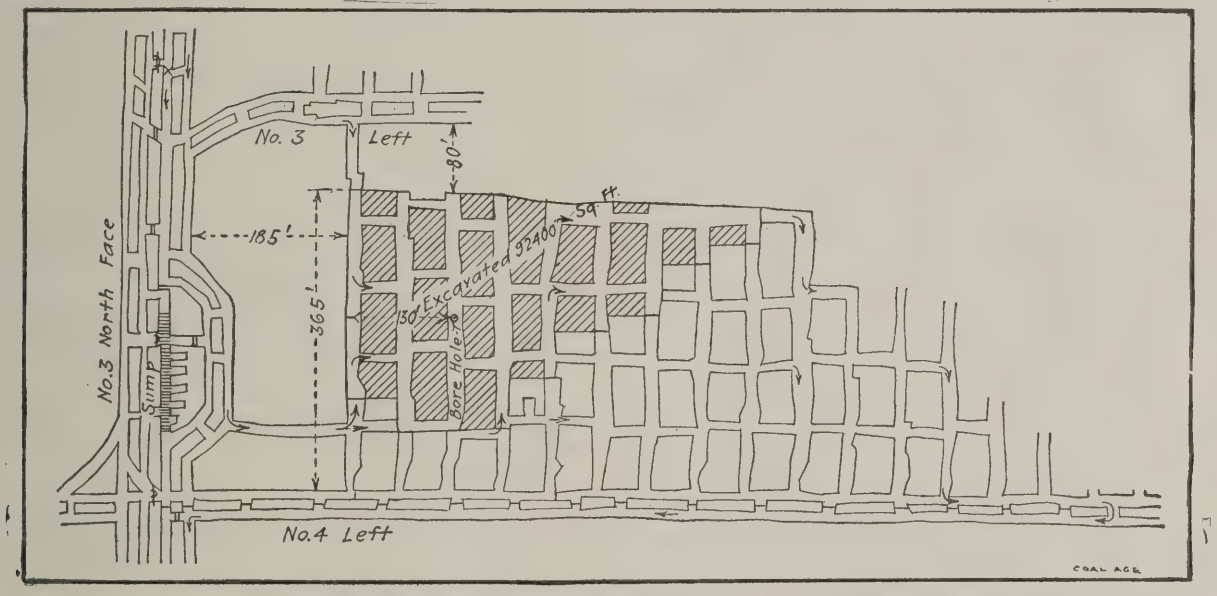
In laying out a boiler plant attention should be given to the space left between the fronts of water-tube boilers and the boiler-house walls or opposite faces of the range so as to enable tubes to be replaced and stokers to be run out for repair and renewal.

Firedamp Reservoirs in Room-and-Pillar Work

By Frank Haas*

SYNOPSIS—Cavities above coal workings, when caving has taken place, often contain large quantities of gas which cannot be removed by ventilation; it is suggested, therefore, that holes be drilled for the purpose of tapping these reservoirs, which are a standing menace to the lives of the miners.

There is a general impression among mining men that since firedamp is found in coal seams, it evidently originated there and that the gases are continually given off by the coal. There seems to be some excuse for such an impression as many publications, and particularly those of foreign countries, tend toward this theory. Whatever may be the case elsewhere, here in West Virginia, we know that the gas occurs below the coal seams and also above the seams, and that it is encountered in all the stratifications. Also, that the gas which we encounter in the mining operations is simply natural gas, perhaps altered somewhat in composition. Such gas is met in all excavations within coal mines, clay mines or stone quarries, and the amount will vary with the permeability of the strata and their local condition.



The method of mining coal in the Pittsburgh seam in the Fairmont region of West Virginia, consists in driving rooms from butt headings a distance of about 300 ft., and then removing the pillars between the rooms on a retreating system. The rooms are started successively, so that the line of advancement is at an angle of approximately 45 deg. with the butt heading and the retreating line of the pillars will be practically the same. The coal, being completely removed, leaves the roof locally unsupported, and such stratifications as are loose, break and fall into the space previously occupied by the coal or the lower roof stratifications.

The height to which such stratifications break and fall depends on the area from which the coal has been removed and also on the nature of the overlying rocks, but it cannot be depended on to follow any fixed rules. Such crumbling and falling either continue until they reach the surface of the ground or if there is not an actual breaking of the surface, the measures will subside and fill the void caused by the removal of the coal.

Ventilation Cannot Remove All the Gas

It is plain, that until there is a subsidence of the surface by either cause, that there is a volume equal to the coal excavated which must be filled with air or any gas which may leak in, and we find in certain localities that firedamp or natural gas does accumulate under such circumstances. The ventilating current of the mine when properly handled, has a tendency and does dilute and convey away in its current this gas, but the tendency is less and less as these falls increase in height and finally fails entirely, leaving a body of gas or mixture undisturbed. Such a condition is a menace and the greatest danger occurs when the final fall comes as a result of the subsidence of the surface, at which time this gas is forced out and into the mine more or less rapidly.

To drill a hole from the surface to the highest point or near the highest point in the fall was suggested as a remedy, but several features are involved which threw doubt on its practicability. In order to test out matters fully, such a hole was put down under the conditions set forth in the accompanying illustration. The hole was of such size as to take a 6-in. casing, but the casing was only carried down a slight distance. When the cavity was reached, the casing was capped until the measurements could be made. The results are shown on the accompanying diagram. The percentages of gas refer to the sum of all other gases than air; while not all explosive, they are at

Section of Mine No. 43, Consolidation Coal Co., Showing Bore Hole

*Consulting engineer, The Consolidation Coal Co., Fairmont, W. Va.

least foreign to the normal mine atmosphere. Unfortunately some minor changes were being made in the mine ventilation during the period of the observations, which would affect both water gage and velocity.

The mine is ventilated with a force fan delivering 175,000 cu.ft. per minute at a water gage of 3.4 inches.

The water gage at the hole when opened was 2.7 in., which was apparently too high, but when the specific gravity of the mixture (about 0.6) is taken into consideration, this discrepancy was explained. It was found that when the hole was first opened it delivered 154 cu.ft. per minute; as the percentage of gas fell off, the water gage became less until the normal pressure was reached (1.8 in.), the volume suffering a corresponding drop to 68 cu.ft. per minute.

At first the atmosphere that came off was nearly all gas, but this dropped rapidly in percentage till the end of the fourth day. Thereafter the percentage and quantity of gas remained constant. It would appear that as the quantity of gas no longer varies, the amount leaving the borehole would be an index to the gas actually formed, which is computed at about 12 cu.ft. per minute.

The area of the base of the gob was measured as 92,400 sq.ft., and the coal being 8 ft. high, would give a volume for the accumulation of gas about 739,200 cu.ft. The observations indicate that the hole gave off in the first four

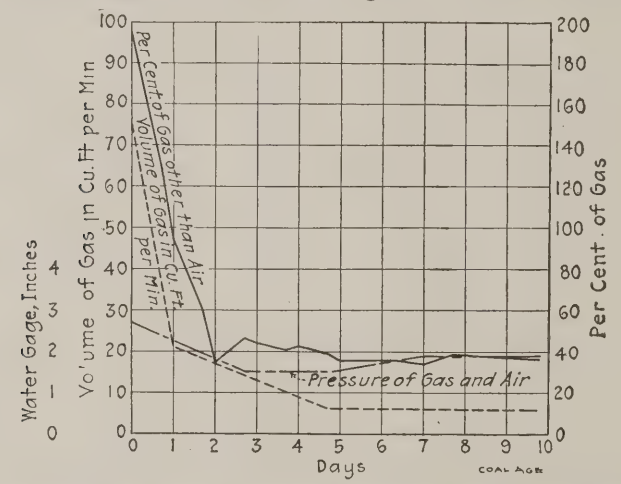


Diagram Showing Volume, Pressure and Per Cent. of Gas from Bore Hole

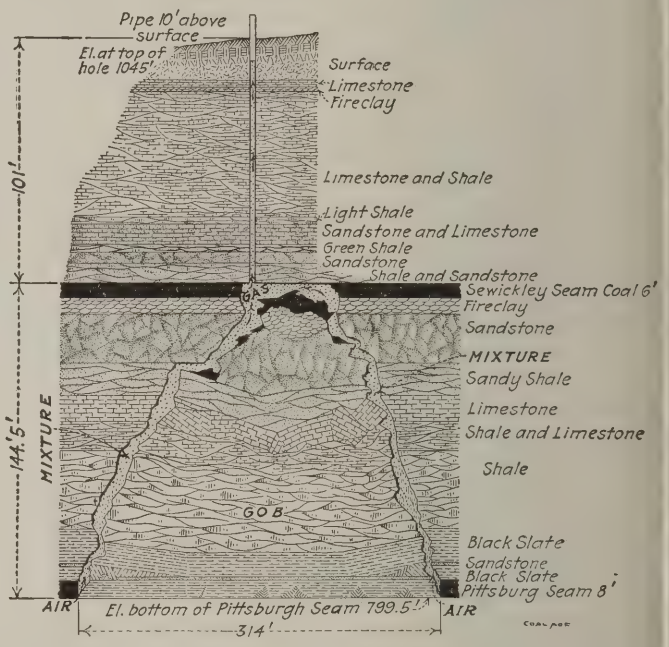
days approximately 245,000 cu.ft. of gas. The mixture of gas and air was not uniform, but the average of the mixture was equivalent to about 25 per cent. gas.



Complete analyses of the gas were not continuously made, but an analysis of the sample taken 24 hours after the hole was opened showed as follows:

CO_2	=	1.00	
O	=	11.66	Air
N	=	44.30	
N	=	10.52	
CH_4	=	32.52	
		100.00	

The peculiarities of this analysis are the low percentage of carbon dioxide (CO_2) and the large percentage of nitrogen other than that normally in air. This indicates that the "gases other than air" consisted of 27 per cent. "blackdamp" and 73 per cent. "firedamp."

Among various unknown factors was the inclination of the fracture line above the coal. The hole demonstrated that this angle was less than 45 deg., but it could not be determined how much less. It is probable that the hole is located at or very near the highest point in the cavity. The question as to what the pressure or water gage would be, could, of course, not be determined, and on this depended the success of the experiment. Pressure varying as the square of the volume, it is evident that with a very small pressure, sufficient volume could not be delivered. This again would depend on the quantity of gas given off. Fortunately, even with the unprepared and incomplete observations taken, all of these facts were sufficiently determined to give quite an accurate approximation of what will exist under other conditions.

The object to be attained in this or other cases of gas accumulation is to have a hole of sufficient size with sufficient pressure behind it, so that the mixture coming out of the hole will be below the explosive limit. In this case, we find that a pressure of 1.8 in. and a 6-in. hole accomplished this when the quantity of gas liberated did not exceed 12 cu.ft. per minute. Should a locality show that it is producing more than this amount, the problem can be solved by increasing the water gage of the fan.

Probable Condition of Roof Falls and Location of Hole in Relation to Coal Pillars

This could be done by putting a regulator in the return and then increasing the water gage until there was sufficient pressure on the hole.

In the case of a disk-type fan where the water gage is rarely over 0.6 in., there would be only one remedy and that would be to put a small ventilator on the top of the hole and exhaust the air. All this presupposes that the mining fan delivers a force current. It is probable that in the case of an exhaust fan, the scheme would not work at all. In fact, there might be a reversal of the current in the hole, due to the specific gravity of the gas.

In using this method of ventilating gobs, several precautions should be taken. There should be no fire near the hole when it is drilled in. While at first the gas would only burn at the top of the hole, later, as the mixture had more air, it would sometime come to the explosive point and the explosion would run down and ignite any explosive mixture which might be in the gob. After the hole is drilled in, the casing should be extended 10 or 15 ft. above the surface to avoid accidental ignition.

Editorials

Purchased Power

Elsewhere in this issue we print a somewhat lengthy article on the subject of "Purchased Power in Bituminous Coal Mining," which sets forth the numerous advantages, real and imaginary, of this source of power supply.

While we would be inclined to agree with much of the text and sentiment of this article, there is also much to which strong exceptions might be taken. We would call particular attention to the following statements:

Many operators know that electricity applied to their workings would increase the output. It is, however, expensive to install a generating plant and equip a mine for electrical operation.

An operation now using steam power and mule haulage can change to electric power at a minimum of expense if current is purchased from a power company. By so doing the greatest item of expense (the power plant) is eliminated.

The general situation confronting the coal producers is such that in the future many of them must take advantage of purchased power. It is the one means of meeting the condition.

If central-station power will be a means to increase the tonnage, reduce production cost, and allow extensions to be made at a minimrm of expense, surely the operators will want it.

Gasoline locomotives are being tried out for mine haulage, but so far have met with indifferent success.

It is not an uncommon thing when investigating conditions at a mine with an isolated plant to find that the power generated per ton of output is as high as 12 to 14 kw.-hr. with the corresponding cost running from 15c. to 25c. per ton. With the intelligent use of purchased power the consumption should not average higher than 2 to 5 kw.-hr. per ton, and the total cost for power should not run above 3c. to 7c. per ton of output.

From the business standpoint, what does it matter whether a man pays a certain amount from his own pocket for a power plant, or pays interest, depreciation, insurance and taxes on an equal investment made by someone else? Let no coal operator contemplating the purchase of power deceive himself or allow himself to be deluded into the belief that by buying current he escapes an investment in power-generating apparatus. For, while it may be true that he is not called upon to immediately pay down a lump sum for a power plant, yet he nevertheless pays all the overhead and operating charges—and usually a plump profit also—on somebody else's investment. These items are about as unavoidable economically as the law of gravitation is physically.

While the central power station furnishing current to coal mines undoubtedly fills an economic need in the fuel-producing industry, it is by no means a panacea for all the ills with which the industry is beset. Even though possibly many small operations may be able to buy current at a less cost than that for which they could generate it, there is no legitimate excuse for crediting purchased power with economies which, of right, belong solely to electrical distribution.

The writer of the article calls attention to the excessive cost of power in small steam-operated plants, and states that 12 to 14 kw.-hr. are often expended per ton of coal mined, with a cost of from 15 to 25 cents, which "with the intelligent use of purchased power," might be reduced to not more than 2 to 5 kw.-hr., costing not to exceed 3 to 7 cents.

When we consider that in not a few mining plants of even moderate capacity, throughout the country, current may be generated and delivered to the outgoing busbars at a cost of from 0.6 of a cent to 1 cent per kw.-hr., it might be pertinent to ask what might be accomplished at mines, such as the writer has mentioned, by the *intelligent* generation and distribution of homemade current?

The writer's remarks on the gasoline locomotive need no comment. Most of our readers are well acquainted with the status, success, possibilities and limitations of this type of motor.

The circumstance wherein the isolated mining station appears to be the most vulnerable is that not in one case in ten are the cost facts known—not one operator in ten knowing with certainty what the power he makes costs or should cost.

Had the numerous mining plants which are now giving way to central station power been properly designed, well built, efficiently maintained and operated, it is extremely doubtful if purchased current could compete with them as easily and as advantageously as is now the case.

The Ethics of Unionism

We are unwilling to believe that a union with a straightforward moral code is impossible. The majority of the workmen, we are sure, are prepared to do what conscience dictates. Consequently, we believe that if the papers of the country generally would insist that employers and employees alike should be honest in their dealings with each other a great change for the better would come over our industrial disputes.

The press has done a great deal to elevate the employer, to make him more amenable to conscience and public opinion. It is certainly time that something was done to make the employee also believe that he is not justified in doing anything and everything which the law does not forbid. A code of ethics is much needed for unionism.

The trouble in Vancouver Island is a case in point. The miners of the Cumberland and Extension collieries operated by the Canadian Collieries (Dunsmuir) Ltd., were discontented over the dismissal of two men and struck. The Industrial Disputes Investigation Act provides that, before striking, the miners or other employees shall submit their grievances to an impartial board of three members, the company and workmen each having a representative on the board. The law does not compel acceptance of the finding of this arbitration commission but it does forbid strikes and lockouts pending the inquiry.

So the miners, to evade this reasonable provision, decided to go on a "holiday" and not on a strike. This was on Sept. 16, 1912. As the United Mine Workers of America has subsidized this violation of the law by

paying strike dues to the holiday makers, the miners at the Cumberland and Extension mines are still continuing their festive idleness.

It was found necessary later to extend the strike and Frank Farrington, at Seattle, Wash., under orders, he says, of John P. White, ordered a strike, in violation of the law, at all the other mines on Vancouver Island. We quote his words because they justify the statement that President White is not sincere in trying to keep the union on a truly honorable basis.

> Therefore, using the authority given me by President White, and in order that we may combat solidarity with solidarity, I hereby instruct you to call a strike of all the men employed in and around all the mines at Nanaimo, South Wellington, and Jingle Pot, the strike to begin May 1 and to continue until a joint working agreement between the United Mine Workers of District 28, and the mine owners on Vancouver Island has been secured; said agreement to carry increased prices of labor and improved conditions of employment. You will also make a diligent effort to secure the names of all men who refuse to respond to the call to strike so that they may be published throughout Canada, Great Britain and the United States.

So these men were to be forced whether they would or not to leave their work without any ballot to express the popular will. White, of Indianapolis, says so, Farrington, of Illinois, approves, Foster, of Nanaimo, also assents and what rights have any of these miners or a majority of them in convention assembled to act counter to their declared will?

A meeting was held by the union at Nanaimo and several officers of the United Mine Workers of America addressed it. Foster, the district president, said "there was no need for a vote on the strike which was called by 2000 workers and now on." The report of the Royal Commissioner, which is the basis for these remarks, goes on to state.

> There was much dissent during the meeting, but those who urged the keeping of their existing agreements were shouted down. When the chairman was asked why the men were not allowed to vote on the question, the answer was that they should join the organization and get a vote.

Meetings were called for a ballot but all kinds of intimidation and disorder were employed. Meantime Foster issued red posters stating "Ballot or no ballot, anyone going to work at these mines will be branded as a scab." Finally the ballot was taken and out of about 2000 men only 478 were present to vote. Of these 432 voted to continue working but they ultimately decided not to go to work owing to the smallness of the vote.

Quibbling, blackmailing, intimidation and despotic methods mark the action of the union at Nanaimo. Since May 1, 1913, the strike or "holiday" has continued over the whole island though the mines are by no means idle. Meanwhile, the men denied a voice, forbidden to keep their contracts, prohibited from obeying the law are being displaced, we fear permanently, by strike breakers from everywhere, including natives of China and Japan.

Making Men

Anyone who has seen the way in which rooms without sights drift helplessly right and left, will soon realize how hopeless it is for us to do work cheaply with the miners now found in our mines. It would be comparatively easy, if our miners were trained, to lay out heading rails in an absolutely true line in plan and then angle off the first straight rails at a given angle from these by the use of a template, and keep the line thus obtained without variation. At least this could be done in a level, or nearly level mine. But instead of this we drive rooms, if sights are not used, so that they "doghole" into one another every 75 or 100 ft. Trained miners are certainly badly needed.

In the track-laying of rooms the poorest of work is usually done, and the delays in gathering and hauling largely arise from the derailments in rooms. It is idle to say that many miners do better and know better than our words indicate. It may be readily granted that this is so, but the first man to put a wrong course or kink in his room has made trouble all along the line.

The coal of the man who has used excellent discretion is taken by his neighbor whose work is bad, and the competent miner must turn to the right or left, or drive a room without a pillar, and his track must twist from side to side, if he would follow the vagaries of his room.

There is today but little pride in heading and room driving. We have seen work fifty years old which was driven without sights and which is far more perfect than some sighted work done today. No one can deny that the loss of coal is largely due to negligent and inexpert work on the part of about 50 per cent. of the miners engaged. Part is due to the obsolete methods of operators, but more is due to the inefficiency of the man at the working face.

It is time to rectify this condition. It is better, we think, to train 90 per cent. of the men in their work, that is the miners, than to expend all our efforts on about 5 per cent.—the would-be foremen.

The old miner was a proud man. He had a trade and knew he had learned it. There was a degree of satisfaction in his labors, such as an artisan always feels. But now there is no art of mining—merely a labor—and in unsighted mines the surveyor is hard put to it sometimes to tell just where he is.

The Coming Spring Agreement

The condition of the United Mine Workers of America is not remarkably flourishing. A surplus of $278,032.30 on Nov. 30 of last year, reduced by the large expenses of the recent session, is not a war fund on which much reliance can be placed. It amounts to hardly a dollar for each member in the *bituminous* regions.

The paid membership also declined noticeably since August, 1913, when it was 409,154. In November, it was 374,358. However, the membership fluctuates so widely that too much emphasis should not be placed on this fact. It is permissible, however, to call attention to the official statement that in November, 1913, the paid membership was smaller than on the same date in 1912 by 12,607 members.

These facts do not bode well for a sturdy resistance this spring. Seeing, however, that some leaders prefer a penniless union, and look upon a reserve fund as an evidence of a base concession to the power of capital, we cannot anticipate that there will not be a bitter struggle for further concessions. The bituminous mine workers cannot fight like those in the anthracite region, for they have only the earnings of 100,000 anthracite workers on which to rely. On the other hand, a strike of the anthracite miners involving only one-third as many men might receive three times as much pecuniary support as one involving all the bituminous mines.

Legal Department

Must a Contract to Sell Coal Be in Writing?

By A. L. H. Street*

SYNOPSIS—By statute in most states agreements for sale must be evidenced by signed writings, if the price exceeds a fixed amount, if no part of the price is paid, and if no part of the property sold is accepted and received by the buyer. What the courts have held in coal-trade cases.

To minimize opportunity for fraud and misunderstanding in commercial transactions, most of the states have enacted a law which provides, in effect, that no contract to sell personal property at a price of $50 or more shall be valid, unless the buyer accepts and actually receives part of the goods, or makes a payment on the price, or unless the contract or some note or memorandum thereof is reduced to writing, and signed by the person to be bound thereby. I understand that this law is not in force in Louisiana, and one or two other states may prove exceptions to it, but, otherwise, it is uniformly operative throughout the country. In a few states, however, oral contracts of sale, involving $30 or more, are governed by this law, which is technically known as the "Statute of Frauds."

To meet the requirements of the statute, it is not necessary that a formal contract be entered into; a memorandum, however, informally written, is sufficient if it discloses the terms of sale. Thus a letter, telegram or receipt may be an adequate memorandum, and a signed offer binds the person who makes it. To satisfy the law, a contract to sell coal must afford means of definitely ascertaining the quantity to be delivered and the price to be paid.

A Coal Contract Which Was Declared Void

Applying the requirement of the Virginia Statute of Frauds that the writing must be signed, the United States Circuit Court of Appeals held, in the case of Richmond Standard Steel Spike & Iron Co. vs. Chesterfield Coal Co., 160 Federal Reporter 832, that a purported contract to sell coal to which was subscribed the seller's name in typewriting, with an unfilled blank under it for the signature of the officer of the selling company who was to sign it, was insufficiently signed, although the company retained the paper after its delivery by the buyer, and although partial deliveries were made according to the terms of the writing. The court decided, however, that the typewritten signature would have been sufficient had the selling company authorized the appending of it to the writing, or adopted it as a signature.

Payment of part of the price, or an amount to bind the bargain, avoids necessity for evidencing the contract by any writing, although good business practice would seem to require the terms of every contract to be in "black and white." The payment must be actual, however, and not simulated. Delivery of a check drawn against ample funds in a bank is equivalent to payment in cash, but execution of a note is not.

To satisfy the clause of the law which avoids the necessity of a writing where the buyer accepts part of the coal contracted for, the coal must pass completely under his control. But it is not essential that, at the time of such acceptance, the coal be measured to determine the amount due on its price.

A New York Case Cited

And, according to the decision of the New York Court of Appeals, in the case of Thedford vs. Herbert, 87 Northeastern Reporter 798, a partial delivery of coal, made after the contract was entered into, renders the agreement of sale valid although the contract was verbal. In this case, it appeared that, after the terms of the sale were orally agreed upon, the seller requested the buyer to confirm the agreement in writing, which the buyer did, stating the price and other terms. Part of the coal was then delivered and paid for. The Court of Appeals rested its opinion as to the validity of the contract on the fact that a partial delivery was accepted by the buyer in recognition of the agreement.

The courts have been frequently called upon to decide that mere delivery of a commodity does not take a contract for its sale outside the Statute of Frauds. It must appear that the delivery was "accepted" by the buyer or by his authorized agent. Thus mere delivery of coal to a carrier does not constitute an acceptance by the buyer, unless he authorized the carrier to make a final acceptance for him. Nor does the fact that coal is otherwise delivered at the place for delivery fixed by the agreement show, of itself, that the coal passed under the control of the buyer.

In addition to contracts for the sale of commodities, the Statute of Frauds usually provides that no promise to discharge the obligation of a third person, and no contract which is not to be performed within a year from its making, and no agreement to grant an interest in land, excepting leases for not more than one year, shall be valid unless it is evidenced in a writing, signed by the person to be bound thereby. Accordingly, the Missouri Supreme Court decided in the case of Reigert vs. Manufacturers' Coal and Coke Co., 117 Southwestern Reporter 61, that a contract for services in working up a market for the company's products was invalid where it was not reduced to writing and was not to expire within a year.

Fraud in Performance of Public Contract—Where a prison coal contractor delivers as pea coal an inferior grade worth $1 a ton less, he renders himself liable to the state in damages on the ground of fraud, although the prison authorities may have been derelict in duty in failing to discover the deficiency in quality. (New York Court of Appeals, People vs. O'Brien, 103 Northeastern Reporter 710.)

More Club Rooms for Mine Workers

The building of five new "mess houses" at as many collieries has been authorized by the officials of the Lehigh Valley Coal Co. They will be of a standard design, based on that of the mess house built experimentally at the Prospect colliery of this company, and their size will depend upon the number of men working at the various operations.

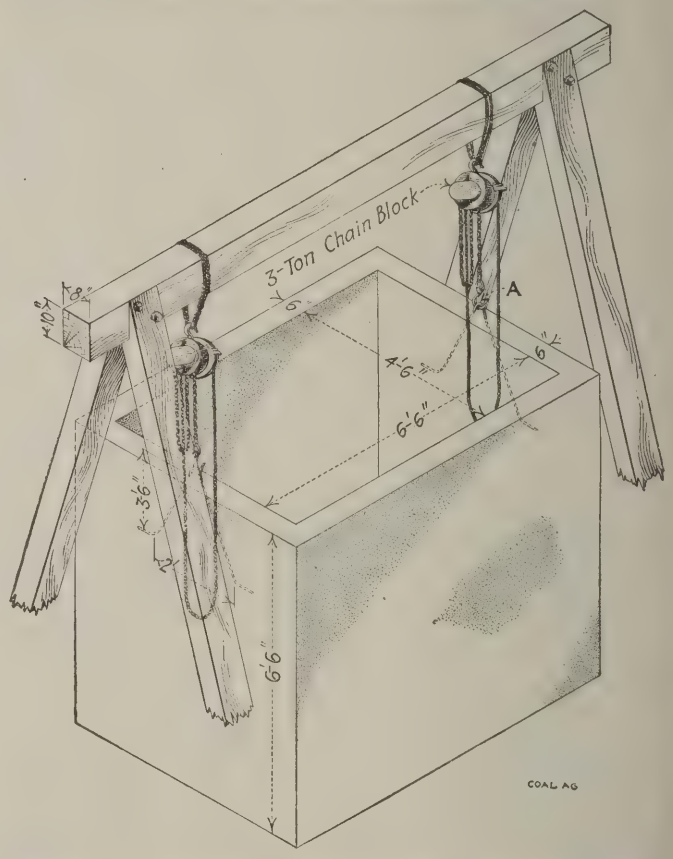
The collieries at which these mess houses, where the men can gather to have their midday meal in comfort, instead of eating in the breaker or in the boiler and engine rooms, are the Franklin, Packer No. 5, Derringer, Park and Buck Mountain. Their construction will be started shortly.

The floors, walls and ceilings of the new mess houses will be of cement, so that they may be easily kept clean and sanitary. They will contain coat and locker rooms, a wash room with hot and cold running water and enameled basins, and a lavatory. The meeting and lunch rooms will be well lighted and heated and will contain benches, tables and simple cooking conveniences.

The mess house at the Prospect colliery has proved extremely popular, especially in the colder months. A number of the mine workers formed a "coffee club," the members of which take turns in heating coffee for the crowd on the simple appliances provided for that purpose, and some of the men bring clean clothes and take a complete bath at the mess house after finishing their work each day.

It is understood that, if these additional houses meet with the same success as that at the Prospect colliery, the system will be gradually extended to all the Lehigh Valley Coal Co.'s operations. Each house is in charge of a man employed to keep it clean and in order, and the mine workers themselves, at the Prospect colliery, have shown their appreciation by refraining from damaging the house or abusing the privileges.

Concrete Vaults in Colliery Villages



By a Pennsylvania Mining Engineer

Sanitation is as important as safety, but it is more generally neglected. One of the most important things about sanitation is the construction of closets of a character which will not serve to spread disease. Some few years ago, we used to see them located over streams and the vaults were usually constructed of rough boards of all widths, lengths and thicknesses; anything was considered good enough for a privy.

Difficulties Where Water Is Encountered

Vaults are now built of concrete and when the excavation is made in dry soil, their construction is comparatively easy. We use old boards to make an inner form and allow the excavation to serve for the outer. When we encounter soil which makes water freely, we must resort to some other method of placing it.

We excavate the pit somewhat larger on all sides than the vault we desire to construct. Substantial timbers measuring 8x12 in. make a good support and these are laid over the hole and a double form is built on them. This is built as nearly water-tight as possible. The timber used is of good quality, for forms should never be built of poor material. Concrete is deposited in these forms and allowed to set for five days. It should then receive two coats of good paint, both inside and out.

Method of Lowering Waterproofed Concrete Vault into Pit Sunk in Water-Bearing Strata

A vault of good size should be 4 ft. 6 in. wide, 6 ft. 6 in. long, and 6 ft. deep, and 6 in. of concrete on the sides and bottom will make a sufficient lining. These dimensions, therefore, fix the size of the form and the excavation.

Lowering the Vault into Place

The vault when completed should be lowered into the pit by means of a horse, which can be built of a piece of 8x10-in. timber, with four 6x8-in. legs. From this can be suspended a 2- to 3-ton chain block. Two men and a helper can easily lower the vault into place.

In order to make the vault water-tight, one quart of crude oil can be added for each sack of cement. The

mixture may be made, 1 part cement, 3 parts sand, and 5 parts stone. Good cement should be used, our practice being to use Universal Portland. Bluestone we find preferable to other stone although slag will give good results.

It will be noted on the top of the vault in the picture that there is a loop of 7/8-in. haulage rope *A* which passes down into the concrete about 3 ft. 6 in. The rope utilized, may have served its appointed time in the mines, and, if so, the grease must be thoroughly burned off it.

AN ALLEY OF A MODEL MINE VILLAGE. CONCRETE VAULT READY FOR LOWERING IN PIT PREPARED FOR ITS RECEPTION

Two loops are placed on the top of the vault and by this it is lowered into the pit.

CONSTRUCTION COSTS

A vault such as that described can be built for $36 complete, the price covering both labor and material. But to keep the price within those limits, 15 must be constructed and it does not pay to build less than ten, as the forms and horse are expensive unless used for the construction of several vaults.

Restoratives

One of the many uses of aromatic spirits of ammonia is to restore persons overcome by asphyxiation, drowning or electric or traumatic shocks. As usually applied there is a considerable doubt as to its effect. The ammonia soon loses strength when exposed to the air; on the other hand, it may be strong and be used without discretion. It is true that an unconscious man is not likely to inhale heavily on the contents of the bottle or rag with which it is administered but he may easily receive too strong a dose. Furthermore, the contents of the bottle may be spilled on the patient, burning him severely.

To avoid these difficulties the Red Cross Society is offering for sale little vials containing the right quantity of aromatic spirits hermetically sealed. The vials are completely swathed in absorbent cotton so that they can be broken in the fingers without the edges of the glass cutting the finger tips. The glass is so fragile that it will yield and break when squeezed strongly and the liquid which escapes has the requisite restorative power. The vials are made in England where the idea of using them appears to have originated. They are termed "vaporoles." The cotton itself is kept in place by a thin netting of silk which prevents the vial from escaping from its cotton coat.

While the inhalation of ammonia from "vaporoles" or otherwise undoubtedly does good, the best way to administer aromatic spirits of ammonia if the maximum effect is desired is to give it through the mouth in water. This method is, of course, impracticable with an unconscious patient. The "vaporoles" are especially serviceable in cases of threatened falling or syncope.

Vineyards and Orchards in Pocahontas Region

Several families in the Pocahontas region are setting out vineyards and orchards on plots which they have rented for a nominal sum. Some of these are three or four years old and are therefore in bearing condition. Scores of others have been set out within the past year and, of course, these will not be harvested for a couple of years yet. The majority of the white miners in this region come from Italy and Hungary and were agriculturalists in their native lands.

At Elkhorn and Crozer one can see on the sides of the hills, patches of ground fenced in, filled with neatly pruned and securely trellised grape vines. On other spots there are peach, apple, pear and other fruit trees regularly laid out. Most of the grape vines have been imported from the countries whence the miners came.

But tilling the soil is not confined to the whites. Hundreds of negro miners of the Pocahontas coal fields devote their energy to gardening. Far up on the tops of the mountain where the land is comparatively level, the negro miners raise vegetables such as they formerly grew in old Virginia, North Carolina and other Southern states. They are not much given to fruit raising. They do not even raise many watermelons, but prefer cabbages, potatoes, beans and the like. By this soil tilling, in their leisure hours, the miners in the Pocahontas field have materially reduced the cost of living and are increasing their savings accordingly.

Work of Rescue Car in Arkansas

Mine rescue car No. 4 of the U. S. Bureau of Mines was for a long time engaged in Arkansas in giving training and instruction to the miners of that field in the work of mine rescue and first aid to the injured. The work at Russellville completed the training itinerary of car No. 4 through Arkansas, which began on Oct. 15 (being interrupted for ten days by the trip to the mine disaster at Dawson, New Mexico) and on January 7 the car returned to headquarters at Pittsburg, Kansas. During this trip through Arkansas the coal camps were visited in the following order—Hackett, Midland, Hartford, Greenwood, Jenny Lind, Huntington, Paris, Denning and Russellville.

A total of 150 miners were given the full week's course of training in mine-rescue work, first aid to the injured, the use and care of safety lamps and safety appliances, and other instruction pertinent to the conservation of life in the coal mines; also 5000 miners and others attended lectures on the car. The spirit and enthusiasm with which the miners and operators entered into this training work speaks well for the future of the coal-mining industry in the state of Arkansas. State Mine Inspector Tom Shaw also worked with untiring energy to make this training work a permanent factor in furthering the safety of mining conditions in Arkansas.

H. D. Mason, Jr., in charge of the mine-rescue car has the following to say with regard to this training work, "I wish to thank the miners, operators, mine inspector, and railroads of Arkansas in behalf of the U. S. Bureau of Mines for their constant courtesies and most sincere interest in this work for the conservation of human life in the coal mines. Never has it been our pleasure to meet brighter and more clever mining men; than those with whom we have been associated during our work through Arkansas, and Doctor Chisholm and myself will leave this state feeling that the work already accomplished will be carried forward by the men at the mines."

Discussion By Readers

Rope Lubrication

Letter No. 1—I have read the query on the matter of rope lubrication, by Superintendent, asking for the records and results of scientific investigation and the practical experience of mining men, in reference to the lubrication of cables with a view to the prolongation of the life of the rope. I note that the editorial comment, in reply to this inquiry, advises, first, the application of linseed oil, COAL AGE, Jan. 17, p. 139. In this connection, I want to draw attention to a few quotations bearing on this question.

In opposition to the use of linseed oil as a lubricant, Redwood says: "Neither raw nor boiled linseed oil must be used as a lubricant, as they quickly oxidize."

Victor Schweitzer, in The Distillation of Resins, p. 155, says: "The thickening of linseed oil results from the absorption of oxygen in the air."

Another investigator of world-wide reputation, found that linseed oil in the presence of moisture and gases, in the New York subway, was converted into a soap and, in this form, served as a carrier of moisture to the metal that it was designed to protect, causing its corrosion.

In the proceedings of the tenth annual meeting of the American Society for Testing Materials, Charles B. Dudley, president of the society at that time, said, in discussing this subject: "If you can so cover your metal that you keep the oxygen out, there will be no corrosion."

I may add, the same argument applies in regard to the use of pine tar as a protective against corrosion. In its hardening process, it also absorbs oxygen from the air. The lime used in neutralizing any acid it may contain is attacked by the chemical action of gases and mine waters, the hydrogen sulphide of acid mine waters converting part of the lime into calcium hyposulphide, and the carbon dioxide of the air and mine water, converting another portion of the lime into calcium carbonate. The former lime salt, in the presence of moisture, again gives up the hydrogen sulphide, which gas attacks the metal, causing its corrosion.

Any mixture of linseed oil and pine tar would possess the combined faults of both of these constituents. The only virtue of such application lies in their great adhesiveness. A prime factor in securing immunity from corrosion in rope practice is the elimination of all oxidizing influences; but this is, in present-day knowledge, a costly operation.

A. C. STALKNECHT.

Pittsburgh, Penn.

[Our correspondent has given some valuable quotations, in connection with the lubrication of hoisting and haulage ropes. These quotations must be taken for what they are worth. The first quotation, from Redwood, undoubtedly refers to the use of boiled linseed oil for lubricating machinery. While there is no doubt of the absorption of oxygen by oils and tars, in the hardening process, there is some question of the conveyance of this oxygen to the iron or steel protected by said lubricant.

The chemical action of gases and acid mine waters on these lubricants destroys, undoubtedly, in time, their protective qualities, but, the question may properly be asked, will not these agents attack the unprotected iron or steel more rapidly than when compelled to act through the protective coverings. The present-day practice of manufacturers and users of wire ropes is as stated in the editorial comment to which reference has been made, COAL AGE, Jan. 17, p. 139. We would suggest that our correspondent, after his severe arraignment of this common practice, should give the readers of COAL AGE a substitute for the applications he condemns.—ED.]

Fan Ventilation

In reading the answer to D. J. Hopkins' question on Fan Ventilation, COAL AGE, Jan. 24, p. 180, permit me to say that I think the way this question is answered may prove to be misleading. It might cause a company to install a fan and, perhaps, fail then to obtain the necessary quantity of air, owing to certain existing conditions in the air courses, which are often very contracted in thin seams, frequently having a sectional area of only 30 sq.ft.

I would like to suggest another question: Assuming the conditions stated by Mr. Hopkins and assuming, further, that both openings have practically the same elevation and that the distance from the present fan to the back opening in the mine is 1¾ miles, suppose that a 6-ft. Stine fan is now installed at the back entrance, capable of producing 20,000 cu.ft. of air per min. against a 1-in. water gage; how much would this second fan increase the quantity of air in circulation in the mine? Assume, for example, that the present circulation of air is 80,000 cu.ft. per min. against a water gage of 3.5 in., and that this circulation is produced by a 12-ft. fan; and that the resistance of the return airway is equivalent to a 1½-in. water gage.

CONSTANT READER.

Punxsutawney, Penn.

Our correspondent has assumed conditions not involved or suggested in the previous question. Mr. Hopkins' question simply asked if the installation of a second fan, working in parallel with the first, would prove satisfactory; or, as he says, "will both of these fans work successfully."

There is no question but that, before making such installation, every effort should be made to increase the circulation in the mine by clearing up the air courses, enlarging breakthroughs and shortening the distance the air must travel wherever this is practicable. The question of the airways being driven in a thin vein and having a small sectional area, does not affect the principle involved in the answer to this question. The principle, in respect to both fans working successfully, will be the same whatever the sectional area of the airways.

Referring to the question proposed by correspondent; namely, the installation of a second fan, located at a back opening in the mine (not mentioned in Mr. Hopkins'

question), this suggestion is extremely doubtful and would only prove advantageous to the extent the distance of air travel is shortened and under certain conditions in which the air current, at some point in the mine, has virtually lost its velocity, becoming dispersed in the workings. The second fan, under such conditions, will act as a booster. We could not attempt to give an answer to the question, how much this fan would increase the present circulation of 80,000 cu.ft. of air per min., under the conditions stated, as we regard this wholly incalculable.

The Certificate Law

Letter No. 16—In the discussion of the certificate law, several correspondents seem to think that all mine foremen and firebosses should be examined every few years. While I feel that a superintendent or foreman of a mine should possess a certificate of competency, I do not concur in the opinion that these officials should pass an examination so frequently. I would ask why a mining man should be required to stand such frequent examination in order that he may follow his vocation when this is not done in other professions. Would it not be just as necessary to require that state certificates, diplomas and licenses should be subject to a reëxamination, in all callings and professions?

The ability to pass an examination does not make a man a successful mine foreman. One correspondent who favors such frequent examination, himself admits knowing a foreman of a gaseous mine, who has no knowledge of gas. If this man was required to pass another examination, would he not probably secure a certificate by the same unfair means he employed to get the first? Again, other candidates who are thoroughly posted on the theory of mining and could pass any examination without a day's preparation, lack executive ability in the handling of men so essential in the operation of a mine.

The mine foreman who is faithful and devoted to his work is learning every day by experience. He is constantly confronted by practical problems in ventilation, haulage, drainage, timbering, methods of mining, etc., that he must master. Ask one of these men who has been "on the job" for several years, how much more he knows now than when he obtained his certificate, and he will tell you that he knew nothing about mining then, in comparison with what he knows now, which shows that he has acquired a vast amount of knowledge in the school of experience.

My opinion is that every mine foreman should be progressive enough to keep abreast of the times by reading books and journals devoted to mining. It is only too true, however, that through the extra work required in the mine and the conferences with the superintendent every evening, after supper, in the office, the mine foreman has little time to himself that he can devote to study.

In the discussion of this question, it should be remembered that the mine foreman, like other men, has many duties demanding his attention a part of the time. He cannot neglect the duties he owes his family and the community in which he lives. Besides attending religious, fraternal, social and other meetings, he must have some time for recreation. When these numerous demands on his time are considered, it seems to me that, having passed one successful examination, the faithful mine foreman should be regarded as sufficiently qualified for the position he holds. I advise all whose time will permit to continue to study and read and aspire to higher things. A man should qualify himself for something better than his present position, remembering that "there is always room at the top."

BITUMINOUS.

Windber, Penn.

Letter No. 17—The discussion of this subject, in the different letters submitted, has interested me very much and leads me to express my opinion in regard to the interchange of state certificates of competency.

I may say nearly one-half of my mining experience was gained in the Clearfield region of Pennsylvania, although I have had practical experience in 37 different mines located in six different counties in this state. While I am not in favor of an interchange of certificates between the different states, I fail to understand why anyone should argue that a man who has obtained his experience in the Clearfield region and has passed successfully the examination required for first-grade mine foreman certificate is not able to successfully manage mines in West Virginia, as stated by one correspondent, Letter No. 5, Vol. 4, p. 912. There are drift, slope and shaft mines in Clearfield County, and the characteristics of the coal seams are somewhat varied, there being gaseous and nongaseous mines in that region. I think, also, that Joseph Virgin will find the same varied conditions in the mines of West Virginia as exist in the Clearfield region of Pennsylvania.

I want to say that our knowledge of mining would be limited indeed if the experience of our ancestors had not been handed down to us, either in verbal or written form. It is the combined experience of this and preceding generations that has brought mining up to its present standard.

In regard to the character of the examinations asked in different states, a simple comparison of the questions asked candidates for mine foreman and fireboss certificates in the bituminous regions of Pennsylvania, during the past several years, with the questions asked in other states will convince anyone that a man who can pass the Pennsylvania examination and has had sufficient experience in the coal mines of this country is well able to take charge of any mine in any state. Notwithstanding this, however, I am not in favor of a certificate of any state being good in another state, because of the fact that there are many men holding certificates of competency who are clearly incompetent.

Speaking of examinations, I think that any citizen of moral character and temperate habits who has had at least five years' practical experience in the coal mines of this country, immediately preceding the examination, should be allowed to sit in an examination in any state, whether or not he be a resident of that state.

In regard to the life of a certificate, since there are a large number of men who neither study nor read mining books and papers after they have obtained their certificate of competency, and others who imagine that they know it all and have nothing further to learn, I am of the opinion that no certificate issued in any state should be good for a longer period than four years. I also believe that the standard of examination should be the same in all states and sufficiently high to secure the greatest efficiency.

BENJAMIN HARTILL.

Johnstown, Penn.

Colorado Strike Investigation

I read with interest the article by A Constant Reader, COAL AGE, Jan. 3, p. 28, in which he quotes a part of the findings of the Federal Grand Jury, sitting at Pueblo, Colo., investigating the Colorado coal strike. I would like to ask, Why does he quote only that part of the findings that is favorable to the Union?

In the absence of any information to the contrary I take it for granted that this correspondent is a union man. I have no fault to find with him in this respect but would call his attention to the fact that in order to present his case in an intelligent manner to the jury of public opinion, he should state all the facts in the case, both for and against his cause.

Inasmuch as he has stated those findings of the jury that were favorable to the Union cause, I will not repeat them, but will mention those that were adverse to the Union. I will also say, in a spirit of fairness and justice, that correspondent did not state *all* of the findings of this jury that were favorable to his cause. For the benefit of those who wish to secure the entire report it may be stated that it was published in full in the *Denver Post* (Colo.), Dec. 2, 1913.

As this jury was composed of nine men holding union cards and nine men without such cards, the charge that it was a fixed or biased jury could not be sustained, as these nine union men would not have brought in the indictments against the heads of the United Mine Workers of America that they did without sufficient evidence to sustain such a finding. The parts of the report not quoted by correspondent are as follows:

"The methods employed by the United Mine Workers are an insult to law-abiding citizens and conservative labor. The miners organization has brought experienced strike agitators into the state and have armed hundreds of irresponsible aliens, who have become a menace to the peace, prosperity and lives of our citizens. The Union has created an open insurrection in southern Colorado and its methods are repudiated by all fair minded organizations. The officers admit their inability to control the miners in the tent colonies they have armed."

"A promise to pay fines," says the report, "is about all that is necessary, in order to become a member of the United Mine Workers of America"; and adds, "The dues are used to support insurrection and lawlessness and, when necessary, to force their demands by intimidation and fear whenever strikes are called, with the result of injuring other trades and the entailment of hardships and privations on the people of the entire commonwealth."

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

ADDITION OF FRACTIONS

In order to add two or more fractions together, or, in other words, to find their sum, it is necessary to reduce them to equivalent fractions having the same fractional unit. That is to say, all the fractions must have the same common denominator. The sum of the numerators will then show the total number of fractional units and this sum written over the common denominator will be the required sum of the given fractions.

Rule—If the fractions have the same denominator add the numerators together and write their sum over the common denominator.

If the fractions have different denominators reduce them to equivalent fractions having a common denominator and add together the numerators of the fractions, writing their sum over the common denominator, as before.

To Reduce Fractions to a Common Denominator—Find the least common multiple of all the denominators for a common denominator. Then divide this common denominator by the denominator of each fraction, in turn, and multiply the numerator by the quotient obtained, for a new numerator and write this over the common denominator.

Example—Reduce the following fractions to a common denominator: $\frac{1}{3}$, $\frac{5}{8}$, $\frac{7}{12}$, $\frac{13}{18}$, and find their sum.

Solution—First find the least common multiple of 3, 8, 12, 18; thus:

$$\begin{array}{r|l} 2 & 3\ \ 8\ \ 12\ \ 18 \\ 2 & 3\ \ 4\ \ 6\ \ 9 \\ 3 & 3\ \ 2\ \ 3\ \ 9 \\ & 1\ \ 2\ \ 1\ \ 3 \end{array}$$

$2 \times 2 \times 3 \times 2 \times 3 = 72$ *least common multiple*

The equivalent fractions are then found as follows:

$$\frac{1}{3} \times \frac{72}{72} = \frac{24}{72} \qquad \frac{7}{12} \times \frac{72}{72} = \frac{42}{72}$$

$$\frac{5}{8} \times \frac{72}{72} = \frac{45}{72} \qquad \frac{13}{18} \times \frac{72}{72} = \frac{52}{72}$$

The sum of these fractions is now found by adding the numerators together and writing their sum over the common denominator, thus:

$$\frac{24 + 45 + 42 + 52}{72} = \frac{163}{72} = 2\frac{19}{72}$$

Therefore, $\frac{1}{3} + \frac{5}{8} + \frac{7}{12} + \frac{13}{18} = 2\frac{19}{72}$ *Ans.*

Example—Add together the following fractions: $\frac{12}{7}$, $\frac{3}{8}$, $\frac{5}{14}$ and $\frac{24}{35}$.

Solution—The least common multiple of the denominators, 7, 8, 14, 35 is 280, which is, therefore, the common denominator of these fractions. Hence

$$\frac{480 + 105 + 100 + 192}{280} = \frac{877}{280} = 3\frac{37}{280}$$ *Ans.*

The Coal Age Pocket Book

SUBTRACTION OF FRACTIONS

In order to subtract one fraction from another, the two fractions must have the same fractional unit, as explained in addition of fractions.

Rule—If the fractions have the same denominator subtract the less numerator from the greater and write the difference over the common denominator.

If the fractions have different denominators reduce them, as before, to equivalent fractions having a common denominator and proceed as above.

Example—From $\frac{9}{7}$ subtract $\frac{5}{9}$.

Solution—Since 7 and 9 are prime to each other, the least common denominator, in this case, is $7 \times 9 = 63$; and

$$\frac{54 - 35}{63} = \frac{19}{63}$$

Therefore, $\frac{9}{7} - \frac{5}{9} = \frac{19}{63}$. *Ans.*

MULTIPLICATION OF FRACTIONS

In the multiplication of fractions, the numerators are multiplied together to form a new numerator and, likewise, the denominators to form a new denominator; and the resulting fraction is then reduced to its lowest terms. The work is much simplified, however, by the process of cancellation, according to the following:

Rule—Express the multiplication in the form of a compound fraction, by writing the numerators of the several fractions above the line and the denominators below the line. Then cancel all factors common to both numerator and denominator, and write the product of the factors remaining in the numerator for a new numerator; and, likewise, the product of those remaining in the denominator for a new denominator.

Example—Find the product of the following fractions: $\frac{14}{25}$, $\frac{10}{21}$, $\frac{5}{6}$, $\frac{3}{2}$.

Solution—

$$\frac{\cancel{7}\ \ \cancel{2}}{\cancel{14} \times \cancel{10} \times \cancel{5} \times \cancel{3}} = \frac{1}{3}$$
$$\cancel{25} \times \cancel{21} \times \cancel{6} \times \cancel{2}$$
$$\cancel{5}\ \ \ \cancel{3}\ \ \ \cancel{2}$$

Therefore, $\frac{14}{25} \times \frac{10}{21} \times \frac{5}{6} \times \frac{3}{2} = \frac{1}{3}$ *Ans.*

DIVISION OF FRACTIONS

The process of division is similar to that of multiplication.

Rule—To divide one fraction by another, invert the divisor and proceed as in multiplication of fractions.

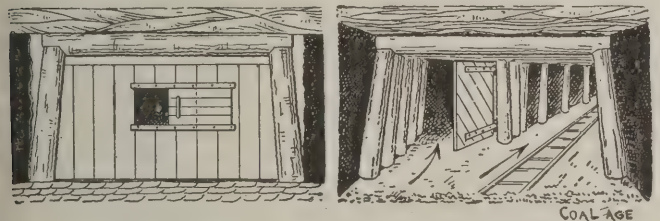
Example—Divide $\frac{5}{6}$ by $\frac{15}{24}$.

Solution—

$$\frac{5}{\cancel{6}} \div \frac{15}{24} = \frac{\cancel{5}}{\cancel{6}} \times \frac{\overset{4}{\cancel{24}}}{\underset{3}{\cancel{15}}} = \frac{4}{3} = 1\tfrac{1}{3}$$ *Ans.*

Inquiries of General Interest

Study Questions--Regulators



In studying some of the questions in the back numbers of COAL AGE, I find two that I would like to have further explained. One of these is in reference to calculating the necessary size of opening in regulators of different kinds.

In answer to the question, COAL AGE, Vol. 3, p. 502, asking for the size of the opening in a regulator necessary to reduce the volume of air in circulation to 15,000 cu.ft. per min., under a ventilating pressure of 6.954 lb. per sq.ft., it is assumed that the regulator is a "box regulator," and the size of the opening is found to be 5.35 sq.ft. I would like to ask how this question can be worked in the case of a door regulator.

X.

Heilwood, Penn.

The usual form of regulator is the box regulator, shown on the left of the accompanying figure. This is a brattice or partition erected in the airway and provided with an opening having a small slide door, by which the size of the opening can be increased or decreased so as to regulate the flow of air according to the requirements.

SHOWING "BOX" AND "DOOR" REGULATORS

In order to pass a given quantity of air through this regulator, under a given mine pressure, it is necessary to calculate, first, the frictional resistance of the airway and the unit pressure (lb. per sq.ft.), for the given quantity of air. Subtracting this from the given mine pressure, gives the pressure due to the regulator. This pressure is then reduced to inches of water gage and the value found substituted in the formula

$$A = \frac{0.0004\,Q}{\sqrt{w.g.}}$$

In the case mentioned by correspondent, the original circulation is given as 60,000 cu.ft. of air passing under a pressure of 6.954 lb. per sq.ft. The natural pressure or the pressure due to friction when this volume is reduced to 15,000 cu.ft. per min. may be calculated from the original circulation. Since the pressure varies as the square of the quantity, the pressure ratio is equal to the square of the quantity ratio. Thus,

$$\frac{x}{6.954} = \left(\frac{15{,}000}{60{,}000}\right)^2 = \left(\frac{1}{4}\right)^2 = \frac{1}{16} = 0.0625$$

$$x = 6.954 \times 0.0625 = 0.434$$

The pressure due to the regulator is then 6.954 — 0.434 = 6.52 lb. per sq.ft.; and the corresponding water gage is $6.52 \div 5.2 = 1.25$ in. The required opening in the regulator is therefore

$$A = \frac{0.0004 \times 15{,}000}{\sqrt{1.25}} = say\ 5.35\ sq.ft.$$

It will be noticed that this question refers to a single airway only, in which it is desired to reduce the volume of air passing by introducing a regulator, which virtually has the effect of lengthening the airway. On the other hand, the use of a door regulator, as shown on the right of the figure, always assumes the splitting of the main air current between two airways, which may be of any size or length. The regulator door is placed at the intake end of the airways where the split is made.

In the solution of a question relating to a door regulator, it is necessary to know the volume and pressure of the main current and the length and sectional dimensions of the airway or split in which a given quantity of air is desired. It is then merely a question of swinging the door to one side or the other, so as to divide the sectional area of the main airway, so that the ratio of area for the split to the total main area will be the same as the ratio of the power in the split to the total power on the air. In other words, the power ratio between the split and the main airway is the same as the area ratio for these two currents.

Suppose, for example, the main intake airway in a mine is 6x10 ft., in which a current of 100,000 cu.ft. per min. is passing under a 2-in. water gage, or a mine pressure of $2 \times 5.2 = 10.4$ lb. per sq.ft. Keeping the power constant, it is desired to split the main current so that 40,000 cu.ft. will pass in one split 5x8 ft., 1000 ft. long. Find the area of opening for this split, using a door regulator.

Solution—The power on the air, in the main airway, at the point of split is

$$u_0 = Q\,p = 100{,}000 \times 10.4 = 1{,}040{,}000\ ft.\text{-}lb.\ per\ min.$$

The sectional area of the main airway is $6 \times 10 = 60$ sq.ft. The sectional area in the split is $5 \times 8 = 40$ sq.ft. The rubbing surface in the split is $2(5 + 8)1000 = 26{,}000$ sq.ft. The velocity of the air in the split will be $40{,}000 \div 40 = 1000$ ft. per min. The power on the air absorbed in the split is then

$$u_1 = k\,s\,v^3 = 0.00000002 \times 26{,}000 \times 1000^3 = 520{,}000\ ft.\text{-}lb.\ per\ min.$$

But, at the point of split, the height of the airway being constant (6 ft.), the area ratio for the split and the main airway, is the same as the ratio of the width of the opening (x) for the split, to the entire width of the airway (10 ft.). Therefore, the width ratio is equal to the power ratio between the split and the main airway. Thus, in this case, opening leading to the split mentioned is

$$\frac{x}{10} = \frac{520{,}000}{1{,}040{,}000} = \frac{1}{2}$$

$$x = \tfrac{1}{2} \times 10 = 5\ ft.\ wide.$$

Examination Questions

Miscellaneous Questions

(Answered by Request)

Ques.—If you had charge of a mine ventilated by equal splits of air and the fan is running at its full capacity and providing efficient ventilation, how would you proceed to work this mine?

Ans.—If the fan is running at its full capacity and providing efficient ventilation in every section of the mine, the several air splits being equal, the further development and extension of the mine workings will depend on making some provision for an increased circulation of air, since it is impracticable to rob any of the splits and, also, impossible to increase the general circulation without increasing the capacity of the ventilating equipment.

Before doing this, however, a careful inspection of the mine should be made to see if the volume of air in circulation cannot be increased, by removing possible obstructions in the airways, or straightening the air courses, enlarging breakthroughs and reducing the distance the air must travel. The question of sinking another air shaft and changing the general plan of the circulation should also be carefully considered. If it is found impossible to increase the circulation in this manner the ventilating equipment must be improved or enlarged.

Ques.—Assuming a single entry and air course, each 4000 ft. long, ventilated under a ½-in. water gage at the entrance; calculate the water gage that would be expected when these entries are extended 2000 ft.

Ans.—Assuming the power on the air remains constant, at the mouth of the mine, the ventilating pressure (pounds per square foot), and therefore the water gage, varies inversely as the quantity of air in circulation. But, for the same sectional dimensions of the airway and a constant power, the quantity of air in circulation varies inversely as the cube root of the length of the airway. Therefore, the unit pressure or the water gage, will vary directly as the cube root of the length of the airway. In other words, in this case, the entries being extended from 4000 to 6000 ft., the water-gage ratio is equal to the cube root of the length ratio; or, calling the required water gage x

$$\frac{x}{0.5} = \sqrt[3]{\frac{6000}{4000}} = \sqrt[3]{\frac{3}{2}} = \sqrt[3]{1.5} = 1.14+$$

$$x = 0.5 \times 1.14 = 0.57 \text{ in.}$$

Ques.—Assuming a pair of entries 4000 ft. long and a water gage of ½ in. at the mouth of the entries; calculate what the water gage should be at a distance of 2000 ft. from the entrance.

Ans.—Assuming a constant power on the air at the mouth of this pair of entries, the unit of ventilating pressure or the water gage varies inversely as the quantity of air in circulation, which, under the same conditions, varies inversely as the cube root of the length of airway, the resistance of which is measured by the water-gage reading. Therefore, the unit pressure or water gage varies directly as the cube root of the length of the air travel. This, in the first case, is the double length of the heading (8000 ft.) and, in the second case, double the distance inby from the gage to the head of the entry (4000 ft.). The ratio will not be changed, however, by taking the single lengths of entries, 4000 in the first case and 2000 in the second case.

Therefore, since the water-gage ratio is equal to the cube root of the length ratio and calling the required water gage x

$$\frac{x}{0.5} = \sqrt[3]{\frac{2000}{4000}} = \sqrt[3]{\frac{1}{2}} = \sqrt[3]{0.5} = 0.79+$$

$$x = 0.5 \times 0.79 = \text{say } 0.40 \text{ in.}$$

Ques.—At a certain mine, at night, the fan running at 90 r.p.m. produces 100,000 cu.ft. of air per min. in the mine. In the morning, this fan running at the same speed produces 125,000 cu.ft. of air per min., with no change in the circulation of air throughout the mine. What is the probable cause?

Ans.—Without a further knowledge of the conditions prevailing in this mine, night and morning, the general arrangement of the circulation and other data affecting the movement of the air, it would be impossible to more than speculate as to the possible cause of this large increase in circulation, in the morning. The reverse of this condition is more generally the case. However, it is possible to assume conditions that would very much retard the circulation of air, particularly in the early hours of the evening and the later hours of the day shift.

The operations of the mine produce greater or less quantities of smoke, dust and carbon dioxide. It is, moreover, possible that the temperature of the mine is somewhat higher in the evening than in the early morning hours. The smoke of shots at the close of the day shift may, under many conditions, be difficult to remove from the mine workings.

A higher temperature in the rise workings of a mine will generally produce a rise air column that will oppose, to a greater or less extent, the circulation of air in these workings; and likewise the presence of the heavier products of combustion in dip workings retards circulation and these gases are difficult to remove. It is very possible that such conditions as these, some or all of them, may operate to retard the general circulation of air in the mine, at the close of the day shift; while they would not exist to the same extent in the early morning hours when the mine workings are cooler and the air is clearer.

Another and more probable condition, however, arises from the habit of the miners, in many mines, of leaving their loaded cars of coal standing on the entries, in such a manner as to block the air. It is the duty of the night shift to haul these cars to the bottom of the shaft or to the parting, where the trips are made up ready for the morning. In each particular case, it would be necessary to make a careful study of the situation in order to ascertain the actual causes of the condition described. In the absence of exact information this can only be surmised.

Book Reviews

THIRTY-FIRST ANNUAL COAL REPORT OF ILLINOIS, by the State Mining Board 1912, Martin Bolt, Chief Clerk, Springfield. xii+423 pp., 5¾x8¾ in. No ill. Cloth boards.

We think it is due to Martin Bolt and the Mining Board of Illinois to call attention to the excellent annual report they prepare. There are some state reports which are perfect models of "how not to do it" so we think we are justified in stating our approval of this Illinois volume. But, on the other hand, there are reports in other states, the methods of which are closely parallel those followed in this book.

The unit of this report is in general not the district, but the county. The latter division is one in which all are interested. No one knows anything about the inspectors' districts and they may have been changed once or more during the current year. They are always subject to relimitation at the will or the whim of the chief inspector or a mining board. No one will use the results for comparison, for nobody cares about an inspection district; the constant shifting of its boundaries and its purely artificial limits make it incapable of being the subject of sentimental attachment. As someone has said, "Peradventure a man might die for his home, he will never do it for his boarding house."'

Divided by counties the Illinois book does not need an index for if the county is known, the desired information can be immediately obtained by turning to the figures and annotations for that particular county. If the town only is specified Rand, McNally or Hammond will supply the political division.

But one commonwealth in particular produces a report in which there is not even a convenient table in which the names of the counties comprehended in the various inspection districts can be found grouped conveniently together. As a result, in order to be sure that a complete search has been made the reader must look through nearly 1000 pages and endeavor to discover therefrom the numbers of the inspection districts in which all parts of a certain county may lie. Two indexes are now provided in that book to which we are taking exception, but one is useless; the other, an index of companies marks a considerable improvement, but should have been added long ago.

Another feature of the Illinois report is that the front page contains a directory of inspectors and that, at the very beginning, there is a summary of the report. The annual mining records of some states are entirely unsummarized and if the figures are to be culled several pages must be scanned. When we know how intelligent the compilers of such reports are, we wonder whether it is the force of an evil precedent, or a lack of clerical help, which keeps them so closely bound to an evil system.

But we cannot indorse all we see in the Illinois report. For instance, we do not like to see mining machines and motors classed alone under makers' names. The various machine and motor makers have many different types of construction, which vary more from one another than machines of the same type made by different firms. Machines should be classed as punchers, cutter bar, breast chain, adjustable turret chain, shortwall chain, longwall chain and Hess-type machines. To this should be added a statement showing whether the machines are pneumatically or electrically actuated. Motors should be classed as air, gasoline, steam, direct-current motors, storage motors, combination storage-and-current motors, crab and reel locomotives. The makers' names could be added if desired.

We believe that when a man is injured in a machine room the type of machine in use should be given, so that some relation might be established between danger and certain types of machines requiring a large amount of free room. We hope these types may rapidly become obsolete. We also believe that the manager of every mine should specify, as in the English collieries, how much permissible powder is used, even if he is not also required to declare what amount is used of each brand.

Finally we should express regret that the fiscal year of Illinois is not the same as the calendar year and that the general rule that the country is the statistical unit is not made universal in the computation f all tables. The argument that the death rate in districts will furnish a key to the activity of mine inspectors is extremely faulty and comparisons of district death rates are, therefore, of little value.

DETAILED REPORT OF MARION, MONONGALIA AND TAYLOR COUNTIES, WEST VIRGINIA. West Virginia Geological Survey. By Ray V. Hennen and D. R. Reger, assistant geologists of the Survey. xvii + 844 pp., 6x9¼ in. 11 Fig., 33 plates.

ATLAS OF MARION, MONONGALIA AND TAYLOR COUNTIES, WEST VIRGINIA. 6¼x9⅛ in., 2 unmounted maps, 35½x41½ in., West Virginia Geological Survey, Morgantown, W. Va. Price of report and maps $2.50. Topographic map alone 50c., geologic and structural map $1 each.

These works are timely in view of the construction of the Buckhannon & Northern R.R. which opens up a large area of Pittsburgh coal described and mapped respectively in the two volumes. In addition to the detailed study and description of all the rocks, coals, limestones, clays, minerals, soils, streams and industries, with hundreds of oil- and gas-well records, coal analyses, etc., occurring within the area and given in this report, the geologic map gives the structural contours on the Pittsburgh coal, and thus is valuable to any one interested in coal, oil, or gas, as it shows the exact positions of all the anticlines, synclines and structural terraces. The suggestions of Ray V. Hennen, the author of the report, as to the location of prospective oil and gas territory are very full and complete in this report. His deductions in previous volumes relative to probable gas- and oil-bearing beds have been frequently verified.

The principal towns included in these counties are Fairmont, Morgantown, Mannington, Grafton, Farmington and Flemington.

It is interesting to note that the geologists have little hope that the Allegheny and Pottsville Series underlie the Pittsburgh formation in this section. East of the Monongahela, the wells and croppings show available coal but west of that river where, because of the depth of its horizon, there can be no surface indications of the fuel, the wells rarely record the Freeport coals and show no signs of the Mercer. Frequently round the rim of the Pittsburgh coal the lower productive measures are still found, but they thin out and disappear as the heart of the upper productive measures is reached. Before erosion occurred, this overlapping must have been more general. It is interesting to note how the coals of the Fairmont region bear out the general rule that Pottsville, Allegheny, Conemaugh and Pittsburgh coals are not found of workable thickness in the same cross-section.

GEOLOGY OF THE NORTHERN SHAN STATES. Memoirs of the Geological Survey of India. Vol. 39. Part 2. By T. H. D. La Touche, late officiating director, Geological Survey of India. vi+379+xli pp. 7¼x10¼ in., 27 plates, 11 fig., pocket with 3 geologic charts; Keegan Paul, Trench, Trübner & Co., London. Price, 4s.

The area surveyed lies around and northeast of Ava and Mandalay in British Burma. Its measures include most of the horizons from Archaean upward with the exception of Lower Tertiary and Cretaceous. The Tertiary beds contain some brown lignitic coal with a high percentage of moisture; the beds vary, one seam in the Lashio field attaining a thickness of 30 ft.

A table of analyses shows that the moisture varies from 6 to 23 per cent., volatile matter from 24 to 42 per cent., fixed carbon from 17 to 39 per cent., with ash between 1.4 and 40 per cent. As this lignite is irregular and is certainly poor in quality, and as it is located far from the coast and so situated that it must come in competition with the Burma oil fields, there is no possibility of its development.

THE COLLIERY MANAGER'S POCKET BOOK, ALMANAC AND DIARY FOR 1914. By Herbert Greenwell, joint editor, Colliery Guardian. 450 pp. +, 4x6½ in. 6 ill. 1 inset map. The Colliery Guardian Co., Ltd., 30 and 31 Furnival St., Holburn, London, E. C., Cloth 2s., Roan 3s., Calf 4s. 6d.

This useful little book appears in its 45th annual edition. We are unable to determine to what extent its contents are new, but much of the information certainly has not appeared in any earlier edition, as it is largely extracted from papers recently given before scientific bodies with some quotations from recent Bureau of Mines' bulletins. The questions set before candidates for mine manager and undermanager at the examinations held November, 1912, and May, 1913, are given in full; also the text of the new British mining act and several Home Office orders. There are many tables of value to mining engineers and much statistical information, especially relating to the mining industry.

Coal and Coke News

Washington, D. C.

On Jan. 27, the inquiry into mining conditions, which has been under consideration for some time past in the House of Representatives and in political circles generally was authorized, through the adoption of the so called "Keating" resolution introduced by Representative Keating. The resolution calls for an inquiry into the state of things in the Colorado coal fields and the Michigan copper district, the work being placed in the hands of the committee on mines and mining. Actual work will be carried on by subcommittees which are to actually visit the districts in question. They will have full authority to subpoena witnesses and require the production of all records and documents.

The investigation will be confined to the coal fields of Colorado in the counties of Las Animas, Huerfano, Fremont, Grand, Routt, Boulder and Weld, and to the copper mines of Michigan in the counties of Houghton, Keweenaw and Ontonagon.

The seven different subjects of inquiry specified in the resolution are: Whether the postal services are interfered with; violation of the immigration laws; whether citizens have been arrested and tried contrary to the Constitution or laws of the United States; whether conditions have been caused by agreements and combinations contrary to law for controlling the production, sale and transportation of coal or copper; whether arms and ammunition have been shipped into the fields for the purpose of excluding the products of the mines from competitive markets in interstate trade; and whether peonage exists or has been maintained. If any or all of these conditions exist, what causes led up to them.

The debate on the resolution was brief. Representative Keating outlined conditions in the Colorado coal fields, declaring that the "constitutional rights of citizens had been trampled upon."

Representative MacDonald, of Michigan, declared that the police power of he state of Michigan had been turned over to men imported by the copper companies. "The time has come for Federal investigation," he said. "The authorities of the state are either unable or unwilling to subdue the disorder."

Representative Kelly, of Michigan, opposed the resolution. He said that if the investigation was to be made it should be conducted by the Industrial Commission, which had ample authority to inquire into the conditions. Representatives Hardwick, of Georgia, and Garrett, of Tennessee, contended that Congress had no authority to make the investigation.

Hearings on Proposed Freight Increase

A beginning has been made in taking the testimony of shippers of bituminous coal who are opposed to the proposed increase of 5 per cent. on all railroads in official classification territory. Three days were set aside by the commission for the presentation of the case of these coal shippers, Feb. 2, 3 and 4, but during Feb. 2 only a small advance was made.

The Pittsburg Coal Co. opened the discussion through its attorney, Frank Lyon, and began by contending that the shippers should not be compelled to put in their case until the roads had finished their arguments. Furthermore, he went on to contend that to grant the proposed increase would practically annul all orders for reasonable rates on coal issued by the commission during the past few years.

Mr. Lyon, who was formerly an attorney in the employ of the Commission, then directed his arguments into technical channels, contending that the railroads operating from the Pittsburgh district to the Great Lakes were not in the habit of keeping separate accounts showing the cost of moving passenger and freight traffic. He requested that the Commission should order separate figures representing these charges to be prepared. The matter was taken under consideration, and it was stated that should it be granted a special representative of the Commission would make them up.

After Mr. Lyon had finished, Edward S. Mead, of the University of Pennsylvania was called as an expert witness for the shippers. Mr. Mead's idea is that there is no good ground for the advance demanded until there can be some general basis of adjustment between the railroads, the employees' unions and the shippers, with the Government as a party in interest overseeing the agreements and guaranteeing that an equitable arrangement is made between the differer parties.

Mr. Mead is also of the opinion that rates at the preser time are exceptionally high on soft coal and whatever done with respect to the proposed increase of rates general there should be no advance in the coal rates inasmuch as suc advance would tend to unduly burden the miners.

Present Waste of Mineral Resources

In a statement issued by the Bureau of Mines as an extra from the forthcoming annual report it is estimated that t present waste of mineral resources in the United States about $1,000,000 per day, and it is claimed that there is urge need for investigation and reform of methods. This ne applies most strongly, it is said, to oil and natural gas. T Bureau estimates that it has been able during the past ye to stop a waste of natural gas amounting to not less th $10,000,000, a sum six times in excess of the total cost of t Bureau's investigations up to date. Continuing the Bure says:

The waste in coal mining is another drain on our nation wealth, which calls for serious and extended inquiry and i vestigation. A preliminary estimate, based upon limited i quiry and examination, indicates an annual waste or loss coal in mining and handling of not less than 250,000,000 to per annum. This represents a loss from our best and mo easily mined coals and those nearest our great centers of i dustry. What is needed in connection with this loss is a tho ough underground survey and examination at certain careful selected areas in each of the important coal fields of t country, with a view to determining the exact conditions u der which mining operations take place and the possibilit of adopting less wasteful methods. With this large amount accurate information laid before the public, it will then possible to obtain the adoption of far less wasteful metho of mining. Such an investigation, thoroughly conducte would cost about $50,000 per annum for three or four yea It is confidently believed that the results of such an investig tion would mean a saving in fuel resources having a value the nation of considerably more than $50,000,000 per annu

HARRISBURG, PENN.

Whether the commodities clause of the Hepburn act effective in preventing a common carrier from transporti in interstate commerce any article or commodity in wh the carrier has an interest, and, if so, whether, the Delawa Lackawanna & Western R.R. complied with the decision the United States Supreme Court which declared the cla constitutional, were the main points to be decided in Government's suit against the Lackawanna, which was argu in the Circuit Court on Jan. 27.

The action was filed at Trenton, N. J., a year ago agai the Delaware, Lackawanna & Western R.R. and the coal co pany, and the case was transferred to this state on expediti certificate of the attorney general.

The Government asked that the railroad be enjoined fr transporting in interstate commerce any coal produced purchased by it and transferred to it before transportat by the coal company and also asked that the existing agr ments with regard to the purchase price of the coal be c celed. The grounds upon which the Government asked t relief are that the coal company is not a bona fide corporati but is "a mere cloak" for the railroad company, and that whole arrangement between the two is a violation of commodities clause and the antitrust laws.

It was contended that the organization of the coal co pany was a "sham," a lawyer's device and a subterfuge to around the law. The Lackawanna people pointed out that coal is mined by a charter right by the railroad company, a it is sold at the mine to the coal corporation and that t coal is then shipped by the railroad to market. They a brought up the question as to whether or not the coal belo to the railroad or to the coal company while in transit, a contended that it belongs to the coal company, and that coal company is an entirely separate organization, not o as to officers, but as to books in every thing that goes i the operation of the concern.

The Government referred to interlocking directorates the two companies and pointed that sons of directors of railroad had been among the incorporators of the coal co pany. The Lackawanna people claim that it is no heino crime in a man being a director in more than one corporati even if it did appear to some people that interlocking dir torates were a "badge of shame."

The Delaware, Lackawanna & Western Coal Co. was organ-ed in 1909 after the supreme court declared the commodi-es clause constitutional. The railroad company declared a ividend of 50 per cent., half of which was used by the rail-oad stockholders in organizing the coal company. It was tated that approximately 4½ tons of the coal transported y the Lackawanna R.R. goes west to one ton that goes east) tidewater.

The Government contended that "the identity of the two ompanies is the same." "The directors are practically the ame and the coal company is financed by the railroad. The tockholders are practically the same and the stock of both orporations is held by comparatively few persons. The coal ompany is not permitted to purchase coal from any other ompany, but the railroad." The Government showed the elationship of officials of the two corporatins and called ttention to E. E. Loomis, as president of the coal company, gitating himself, as vice-president of the railroad, over reight rates. The court reserved its decision.

After the conclusion of the trust suit hearing a petition vas presented by the railroad company, asking that it be xcepted from the decree canceling 6 per cent. contracts made n the suit brought by the Government against the Reading ompany and others in 1907. The ruling was made by the upreme court and affected the Delaware, Lackawanna & Western R.R. in two contracts with the People's Coal Co. at cranton and the George F. Lee Coal Co., at Plymouth. Also he contracts between the Hillside Coal & Iron Co., and the ackawanna Coal Co., Ltd., and the New York, Susquehanna Western Coal Co., and Jermyn & Co.

The attorneys for the Government informed the court that here was no desire to press for the cancellation of these con-acts, and the court instructed the lawyers to submit a de-ree under agreement for approval.

An Examiner Is Appointed

Appointment of an examiner to take testimony and the miting of time in which to submit evidence in the suit of he Government against the Reading and other coal-carrying ailroads brought in the Federal Court last October, were ncorporated in a decree filed by Judge Gray, on Jan. 28, and harles H. Guilbert, an official court stenographer was ap-ointed examiner.

The court stipulates in its decree that the Government hall conclude the presentation of testimony not later than far. 10 next, and the Reading company and others must close ll its proofs by Apr. 24. The special examiner is instructed o file with the court a transcript of the testimony taken by lay 23.

The original suit to dissolve the so called anthracite coal rust was filed in 1907. After an extended litigation in the ederal and the United States supreme courts, it was de-ided to terminate the old action and begin new proceedings. his was done in October last and these defendants were amed by the Government: The Reading company, the Phil-delphia & Reading Ry. Co., the Philadelphia & Reading Coal Iron Co., the Central R.R. of New Jersey, the Wilmington Northern Rys. Co., the Lehigh & Wilker-Barre Coal Co., the ehigh Coal & Navigation Co., and the Lehigh & New Eng-nd R.R.

A Demurrer Will Be Filed

Attorney-General Bell has announced that a demurrer ould be entered by him to the action in equity brought to st the constitutionality of the anthracite coal tax law. The emurrer will be entered in the Dauphin County court within short time, and it is probable that the question of juris-ction under the circumstances will be raised.

During the week the Lackawanna County Court refused to rant an injunction to Mine Inspector Reese of the fourth strict to have the People's Coal Co. stop mining operations the surface veins in Scranton. The court did not dismiss e injunction bill, however, the latter being retained in der to allow either the mine inspector or the coal company resort to arbitration for the purpose of deternining whether ere is any necessity for flushing the open chambers men-oned in the suit

The court declares that "No question of surface support is stake," inasmuch as no private right either of person or operty is concerned.

On Jan. 28, Judge Edwards, of the above county court, de-ined to grant an injunction to restrain the Scranton Coal o. from mining in the neighborhood of the Graff Furnace o. property. The plant of the latter was damaged by mine ve settling a year ago.

The court found that the reservation clause in the deed surface property purchased by the Furnace company, gives e Scranton Coal Co. the right to mine coal and does not ll for providing support to the surface.

This is the case which brought from the manager of the plant, a charge that Judge Newcomb was holding up de-cision in the case so that a hearing could not be had before the supreme court at the session to be held in February. The decision of Judge Edward's makes this possible.

PENNSYLVANIA

Anthracite

Upper Lehigh—The Upper Lehigh Coal Co. is sinking a new slope to tap a small vein underlying the Buck Moun-tain seam. The new vein is from three to five feet in thick-ness and underlies all of the old No. 1 workings, which up to a few years ago were considered the lower veins.

Lopez—Three locals of the United Mine Workers of America have been established in the Sullivan County min-ing section, and union organizers say that all the workers of that scction will be strongly organized within a few weeks. About 1500 men are employed in the district. The wage scale in effect is about the same as the scale of the Wyoming anthracite region.

Beaver Meadow—Discovery of a 7-ft. vein of rich an thracite coal on the Penrose tract of 600 acres, between Beaver Meadow and Weatherly is reported. H. D. Stimson, a coal prospector, has reported on the discovery to the Penn Forest Coal Co., of Philadelphia, which owns the land.

Nanticoke—Surface settlings in the vicinity of Market and Broad Sts., which have been occurring for the past few weeks, broke out again on Jan. 29, damaging several prop-erties and causing several gas pipes to break. Several large cracks are evident throughout the town.

Lansford—All men employed in the mines of the Lehigh Coal & Navigation Co. have returned to the old system of working through the dinner hour so that they can get home one hour earlier in the evening.

Bituminous

Indiana—The Penn Mary Coal Co., one of the largest operations in the state, will close down for an indefinite period. Slack orders and necessary repairs are given as the reason. The Penn Mary Coal Co. has recently had the finish-ing touches put to a number of cottages for the miners, bearing out the statement by some of the state mining offi-cials that Heilwood is the model mining town of Pennsyl-vania. The coal company operates a modern sanitary dairy, the milk being supplied to the officers and miners alike at a low cost. Another feature of the place is a 100-acre truck farm on which are raised all kinds of vegetables for the use of the company employees.

Uniontown—Urging that a central mine-rescue station similar to those proposed for Fairmont and Clarksburg, W. Va., be established in the Connellsville coke region. Isaac G. Robby, inspector for the 5th Bituminous District, recently expressed his intention of taking up the matter with coke operators of the region.

Smock—Charging that S. P. Hooper entered the Colonial mines in an intoxicated condition with the safety of all of those employed in the mine in his hands, complaint has been filed against the man by Inspector P. J. Walsh, of the 9th Bituminous district.

Connellsville—Caught in the act of stealing coal cars in the Trotter mines on Jan. 23, Pompey Fitts was arrested and placed in jail pending a hearing. Fitts has been sus-pected for a long time, and a close watch was kept. He would remove the checks from the wagons of coal dug by other liners and put his own upon them. The checks of the rightful owners of the coal were destroyed. Each wagon of coal was worth 85c. and as the result Fitts was getting about twice his regular pay.

Pittsburgh—It is reported on good authority that plans are about consummated for taking the Four States Coal Co. out of the hands of the receiver by Mar. 1. The assets of the company are said to be in excess of the liabilities. This firm, together with other Jones interests, has been man-aged by a receiver since Dec. 6 last.

WEST VIRGINIA

Bluefield—Col. Jas. S. Browning is seriously consider-ing the development of his coal property near Falls Mills, and plans are already under way whereby a mine is to be opened at the mouth of Mud Fork near the Norfolk & West-ern dam. The location is about 1¼ miles from Falls Mills station and the drift mouth will be located on the Lee Marsh property.

An effort is being made among coal operators to break up the habit prevalent at many mines of shooting from the solid. In Raleigh county, the E. E. White Coal Co. has de-clined to continue in employment any man found violating

the mining law in this respect, thus, endangering the lives of other miners as well as property.

Mt. Clare—A class in first aid work for the employees of the Hutchinson Coal Co. was recently organized here. About 40 men were enrolled, and much interest was displayed in the work. When the course of study is completed, it is the intention to organize two teams for service at the two mines of the company. These men will be kept in training and ready for any emergency that may arise.

ALABAMA

Cullman—It is expected that a reorganization of the Cullman Coal & Coke Co., which was put into the hands of receivers on Jan. 26, on account of a disagreement in the management, will be effected at an early date. Properties of the company are located near Bremen, Ala., consisting of a large tract of land and a private railroad connecting with the Louisville & Nashville at Cullman. Much money has been spent on improving and opening up the property, the most modern improvements being installed. The Cullman Coal & Coke Co., while having a few local stockholders, is composed mostly, and financed by Holland capital, Queen Wilhelmina being one of the largest stockholders.

TENNESSEE

Jellico—Seventy-five nonunion miners in the Blue Gem mines struck last week because of the discharge by the management of check-weighmen J. H. Duncan, G. J. Strunk and Grover Hickey, who entered a protest against the large size of the screens used. Manager James F. McPherson, who discharged the men, stated that the complaint was baseless, and that the screens used in the mines are of the kind authorized by the laws of Tennessee.

KENTUCKY

Madisonville—Definite announcement has been made that the Deep Water Coal & Coke Co., recently organized, with headquarters at Evansville, Ind., has acquired control of over 20 mines in the Henderson and Madisonville districts of western Kentucky. It is stated that contracts covering the transfer of these mines to the company have been closed, and that details of the deal are now being completed. The capitalization of the company is not known, but it is understood that $6,000,000 is involved in the deal. A number of the mines have not been actively operated of late, but others are now marketing coal; and the intention of the company is to place all of the properties in first-class condition, for the purpose of reaching a large production, to be handled by river to New Orleans for foreign markets. A large acreage of undeveloped coal land has also been acquired by the company, upon which new mines will be opened as soon as possible.

OHIO

Dayton—The W. P. Rice Coal Co., of Dayton, Ohio, will open a new mine at Palos, Ohio, in the Sedalia seam in the near future. A shaft has been sunk and $75,000 will be spent on equipment.

Cleveland—Ohio operators with offices in Cleveland let it be known that their delegates to the joint convention of operators and the United Mine Workers of America have positive instructions to enter negotiations with the wage-scale committee only after an agreement to abolish the check-off system of collecting union dues from the miners has been reached. They also are instructed not to make a wage contract providing for payment of miners on any basis other than the lump-coal plan now in force.

It is claimed that the screen-coal bill, if mines were operated according to its provisions, would increase the cost of coal 10 to 12c. a ton. The operators are emphatic in their statements that they cannot stand this increase and compete with West Virginia products. West Virginia coal has been the bug-bear of Ohio and Pittsburgh operators for years and the plea that West Virginia must be curbed is not a new one in a crisis.

INDIANA

Terre Haute—It is believed that the output of this field will be the smallest for January that it has been in seven years. Some operators recall that there have been seasons when hardly freezing weather prevailed until February, and then the short month gave enough zero temperature to make an average winter coal consumption. Such a February is now the only hope for the revival of the domestic coal trade. There is, however, an appreciable increase in the demand for steam coal, and the reports are for a revival in the industrial world.

Jasonville—The 200 miners who have been idle several weeks on account of a strike at the Queen Coal Co.'s mine near here went back to work on agreement that the decision by a board of arbitration should apply for all their working time.

ILLINOIS

Pana—The Pana Coal Co. has announced a suspension of operations at Mine No. 2 ordering all men to take out their tools. Three hundred miners are thrown out of employment. Falling off in business is assigned as the cause.

The Elly Coal Corporation has announced that plans have been completed for opening its 30,000 acres of coal lands in Christian, Montgomery and Macoupin counties. This comes as encouraging news to several thousand coal miners who have been thrown out of employment during the past month by the suspension of operations in many of the largest mines in this section of the state.

Girard—Three mines operated by the Superior Coal Co., at Girard, turned out 281,183 tons of coal in the month of December. This was more than the output of any single month in the previous history of the mines. For the first week in January, these operations averaged a daily output of 11,981 tons.

COLORADO

Trinidad—A parade of striking miners and sympathizers, on Jan. 23, was dispersed by state militiamen using clubbed rifles and sabres. Several arrests were made, among them being seven women.

ARKANSAS

Fort Smith—One thousand union coal miners, employed by the Central Coal & Coke Co., of Kansas City, Mo., at Hartford, Huntington and Bonanza, went on strike Jan. 29. The union alleges the company refused to abide by the decision of the district arbitrator who reinstated four unemployed men.

OKLAHOMA

Sutter—Fire in the wash house of the local coal mine on Jan. 22 destroyed the building, and the miners lost much of their clothing.

SOUTH DAKOTA

Rapid City—J. P. McElroy and associates are carrying on diamond-drill operations near Interior, in the hopes that coal deposits will be found of sufficient size to warrant working. Indications point to deposits of coal, but the extent of the same has never been determined. A company has been incorporated and will drill for oil on the ground adjoining.

UTAH

Storrs—On Jan. 26 an avalanche destroyed several houses and killed three persons. Among the dead were two Greek miners.

WYOMING

Glenrock—While drilling for water on the Higgins ranch, two miles from here, a good grade of oil was encountered at a depth of 100 ft. Preparations have nearly been completed for installing an oil rig and developing this field in different places.

FOREIGN NEWS

London, England—London's coal strike came to an end Jan. 28, when the men returned to work on the old terms, except in the case of the employees of Sir Edwin Cornwall, who granted the union's demand.

PERSONALS

Governor Tener, on Jan. 29, appointed Edwin Ludlow, vice-president and general manager of the Lehigh Coal & Navigation Co., of Lanasford, as trustee of the State Hospital at Coaldale.

John W. Johnson, a colored miner of Riverton, Ill., recently settled a $25,000 damage suit against his employers for $750. The settlement came by an agreement after the suit was called for trial.

Robert B. Maloney has been appointed general superintendent of the mine of the Davis Coal & Coke Co., with offices at Thomas, W. Va., in the place of Harry Sharp, who resigned to enter business for himself.

John Jarnigan, organizer for the United Mine Workers of America, was given a verdict of $5000 against the Pennsylvania Coal Co. by a jury in the United States court at Fort Smith, Ark., recently. Jarnigan sued for $30,000, the amount being reduced materially by the decision.

Safety Superintendent of Ohio mines, J. M. Roan held several meetings with miners recently in an effort to install better mining methods. He recently addressed two meetings, one at Martins Ferry and the other at Barton, and later a meeting of miners of the Crooksville district at Crooksville.

Edward J. Corrigan was elected to the presidency of the Kansas City Midland Coal & Mining Co. at a recent meeting of stockholders. He fills the vacancy created by the death of the late Bernard Corrigan. The new president, who formerly was secretary, has relinquished the latter office, but retains that of treasurer. Emmet Corrigan has been made secretary. The company's mines are located in the Novinger, Mo., district.

A. E. Williams, for many years lake freight agent of the North-Western Fuel Co., with offices in the Rockefeller building, resigned recently. E. P. Carey, of St. Paul, Minn., secretary of the company, and J. L. Forepaugh, of the St. Paul offices, arrived in Cleveland to take charge. Mr. Williams was immediately relieved as he had requested and Mr. Forepaugh was placed temporarily in charge. No decision has been reached as to who will succeed Mr. Williams.

OBITUARY

George W. Barager, general manager of the Pardee Bros. & Co., died on Jan. 27, at the Medico-Chi Hospital at Philadelphia. He went to the hospital for the purpose of having an operation performed for a throat affection, and while under the anaesthetic, died from heart failure. Mr. Barager was born in Hazleton, graduated from Lehigh University in mining engineering in 1900. He entered the employment of the Lehigh Valley Coal Co. as district superintendent, and succeeded A. W. Drake as general manager of the above company a short time ago. He was also a director of the Freeland Mining & Mechanical Institute, and chairman of the Board of Education of the Y. M. C. A.

CONSTRUCTION NEWS

Woodward, Ala.—The Woodward Iron Co., operator of furnaces, manufacturer of coke and miner of coal, will start immediate work on the construction of 30 modern byproduct ovens at a cost of approximately $400,000, the ovens to be located at Woodward, Ala.

Pikeville, Ky.—The Sharon Coal & Coke Co., of Newton, Penn., is beginning the initial work on a big coal-mining development on Blackberry Creek in Pike County and will build a first-class industrial coal-mining city and expend several million dollars in the work. The home office of the company is in Newton, Penn., while offices will be retained in Huntington.

Woodward, Ala.—In connection with the 30 by-product ovens to be constructed by the Woodward Iron Co. at Woodward, Ala., the American Creosoting Co. will build a creosoting plant at Woodward, utilizing the coal-tar from the by-product ovens. The plant, work on which will start immediately, will consume approximately 6,000,000 gal. of coal tar yearly. The plant will cost $250,000.

Whitesburg, Ky.—It is reported that track laying on the line of the Carolina, Clinchfield & Ohio R.R. through the "Breaks" of the Big Sandy has been started between Elkhorn City, Ky., and Dante, Va., and will be rushed to completion as soon as possible. The tunnels on the line, 40 in number in 32 miles, are completed, and the remainder of the construction work will not take long, it is believed.

Pittsburgh, Penn.—The Dravo Contracting Co. has just been awarded the contract for the complete construction of two modern concrete-lined shafts for the Ford Collieries Co. on its property between Bakerstown and Curtisville, Allegheny County, Pennsylvania. The Ford company is contemplating the construction of a plant modern in every detail and ground will be broken in February for the sinking of these shafts.

Quicksand, Ky.—The Wolf Valley Coal Co. which recently purchased 2000 acres of coal land near here will start at once the initial work on a first-class coal-mining plant—the largest in Breathitt County. The new coal operation is to be reached by a five-mile spur line of the Lexington & Eastern from Haddix, construction of which has already been started. A first-class coal-mining industrial city will spring up, its building having begun.

NEW INCORPORATIONS

Little Rock, Ark.—The Southern Coal and Land Co. has surrendered its charter.

Cleveland, Ohio—The Northern Coal & Dock Co., of Cleveland, Ohio, has filed papers with the secretary of state increasing its capital stock from $300,000 to $500,000.

Grand Junction, Colo.—The Winton Coal Co. has been organized with a capital of $50,000. The incorporators are Susie B. Fletcher, Howard G. Fletcher and Susan J. Winton.

Akron, Ohio—The North Branch Coal Co., of Akron, Ohio, has been incorporated with a capital stock of $100,000 to mine and deal in coal. The incorporators are William McConahy, F. W. Robson, H. L. Houk, M. D. Kuhlke and H. A. Hine.

Shelby, Ky.—The Shelby Coal Co. has been organized with $60,000 capital to develop the old Bartley coal tract near here on the Sandy Valley & Elkhorn R.R. Work will start within 60 days. J. W. Morrell, W. M. Smith and others are the incorporators.

Salem, Ohio—The capital stock of the Salem Mining Co. will be shortly increased from $75,000 to $150,000. The company has purchased extensive coal lands adjoining its present holdings which will be developed during the present summer. Charles Estep is president, M. C. Yoder, vice-president, while J. E. Morgrett is superintendent and purchasing agent.

INDUSTRIAL NEWS

Piedmont, W. Va.—The Elkins Coal & Coke Co. has secured a large coal contract from a New York firm. The order calls for the delivery of 10,000 tons per month for one year at New York City. Shipments have already begun.

Sandusky, Ohio—The city of Sandusky has pledged $50,000 toward the improvement of the harbor at that point. This money is to be provided on condition that plans and specifications prepared by United States engineers are approved. It is proposed to deepen the channel to a uniform depth of 23 ft., extending the Cedar Point jetty and build the pier at the end of the new lighthouse which will cost $450,000.

Washington, D. C.—Kentucky coal operators on Jan. 27 complained to the Interstate Commerce Commission that the Louisville & Nashville and other roads operating in southern, and central western territories, including central freight association territory, charge unreasonable and discriminatory rates on coal outbound and other traffic inbound, to and from all points in the territories in which these roads operate.

Columbus, Ohio—According to a report recently issued Ohio shipped 6,176,683 tons of coal via the lakes to the Northwest during the season of 1913 as against 4,676,000 in the previous season. Lake shipping was the mainstay of the coal trade in Ohio during the months of navigation. The outlook for an active lake trade in 1914 is not bright as there is a large tonnage on the docks of the upper lake ports ready for movement to the interior.

Indianapolis, Ind.—Secretary B. F. Nigh, of the Michigan-Ohio-Indiana Coal association submitted an interesting report of the work of the organization at a meeting of the officers and board of directors at Indianapolis recently. He showed the present membership to be 1716 and rapidly growing and predicted that it would not be long before practically every dealer in the three states would be united with the organization. The annual meeting of the association will be held at Indianapolis some time in June, the exact date to be fixed later by the local committee in conjunction with the president and secretary of the association. It will be only a two-days session with one evening given over to entertainment. Entertainment tickets will be given only to those who attend the business sessions of the convention. Shippers will not be asked to contribute toward the entertainment.

Coal Trade Reviews

General Review

Concessions on domestic sizes of anthracite the rule. April discount expected on individual coal by Feb. 15. Rigid curtailment in bituminous and sellers offering all kinds of inducements. Anticipated suspension still fails to start any buying movement and market continues flat.

The anthracite market is replete with signs of an abnormally depressed condition. All the large hard-coalers, without exception, are under restricted operation this week, and the curtailment is spreading even to the individuals. Moderate concessions on the regular circular for prepared sizes are readily obtainable, and conservative members of the trade expect a sharp break to the Apr. 1 discount by the middle of the current month, these prices already being quoted in some exceptional instances. Companies are eagerly seeking orders, which are promptly filled, and the situation is particularly flat at tidewater. The steam sizes are the only ones to show any strength; under the restricted production, the supply of these has become so short as to command premiums in some instances.

Bituminous agencies are instructing the mines to shut off shipments, and there is a reduction in the amount of consignment coal on the market which has had a steadying effect upon the soft-coal situation. As a result, circular prices are somewhat better maintained, although it is not yet believed that the market has touched the bottom. There are some inquiries on contracts for the new year, but nothing significant has developed as yet. Consumers are not showing any inclination to meet the high level of last year and indications point to a considerable delay in getting together. Shippers, as a rule, are offering all kinds of inducements, and consumers are getting a substantial advantage in their fuel costs.

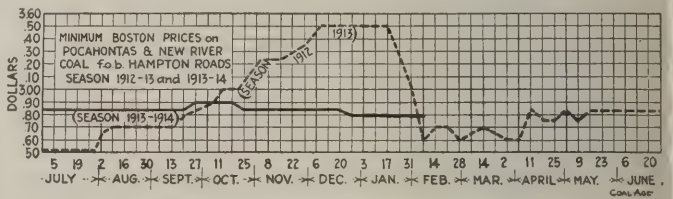
The opinion prevails in the Pittsburgh district that an early settlement of the new wage scale will be effected, but reports from other points are of such a contradictory nature as to throw considerable doubt on this opinion. In any event, the possibility of a suspension has failed to stimulate business, and the demand continues limited with price-cutting the rule; the movement on contracts is light, and the domestic grades are the dullest for years.

A large amount of demurrage coal is reported in Ohio, and the Northwest, while the general absence of any sustained demand, together with the heavy over-supplies, has resulted in a condition bordering on demoralization. Expectations of a suspension in mining seem more prevalent here, and some buying is noted in anticipation thereof. Heavy chartering of lake vessels was the feature of interest during the week.

The January dumpings at Hampton Roads will be lower than the December figures, but in spite of the light movement, prices are well maintained, and no important cutting of the circular is anticipated, although there are large accumulations. Southern operators are curtailing production in hopes of stimulating business, but there is little change in the situation there.

A scarcely perceptible improvement in the Middlewestern market is noted, with a slightly increased demand from the Northwest. There is still considerable coal on demurrage, however, and the market is not materially changed.

EASTERN MARKET



BOSTON, MASS.

A few early buyers entering the market but nothing significant so far is heard. Trade extremely dull. Inland prices slightly better now that consignment coal has been absorbed. Restriction general among operators. Anthracite moving mostly to Eastern storage depots, an unfailing sign of dull business.

Bituminous—A few of the large mills who are usually early buyers have come into the market this week for their usual supplies of Pocahontas or New River. There is therefore a mild scurrying on the part of some of the agencies to play for position but so far nothing significant has been reported. The $2.85 basis is apparently better maintained than a week ago and only a few shippers are now making concessions. Spot sales, however, are still of small tonnages and it cannot be said the market is really any firmer. It is more that the curtailment is so general that coal is not piling up at the piers to the degree it was a fortnight or so ago.

New England trade is certainly dull. Some buyers are finding that they so far over-bought last year that they are not likely to buy this year until June and such instances are more frequent than might be supposed. It is some indication of the state of things when no one of the three large cargoes that foundered in the January gale is to be replaced by other shipments, at least not for the present.

Coal for distribution inland shows a slightly better tone, due more however to the disappearance of recent "market cargoes" than to any improvement in demand. Manufacturers are still cautious and coal is not the only trade that is slow and apathetic.

All the Pennsylvania shippers are trying hard for spot business and offering all the inducements they dare, but the movement is light and confined largely to the quality grades. Georges Creek mines are also under restriction, but with no concessions from season prices.

Anthracite—The companies are keen on getting business but the weather has slumped again and retailers are still holding back. Those shippers who own storage depots in this territory are loading up their barges for these points, which is always an unfailing sign of extremely dull times in anthracite.

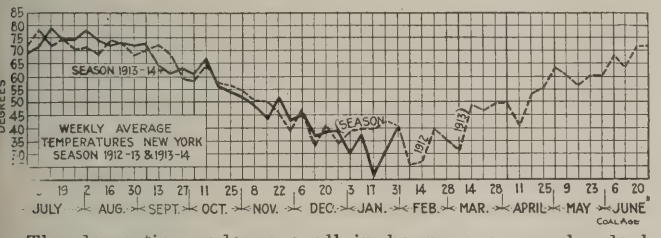
Current wholesale quotations on bituminous are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.95@1.50	$1.25@1.55	$1.67@1.77	
Philadelphia*	2.20@2.75	2.50@2.80	2.92@3.02	
New York*	2.50@3.00	2.80@3.10	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.80@2.85
Boston†				3.58@3.63
Providence†				3.58@3.68

*F.o.b. †On cars.

NEW YORK

Does not seem to be any market whatever for prompt soft coal. Prices moderately good and holding firm in spite of adverse conditions. Slump in the prepared sizes of anthracite to the April circular anticipated by Feb. 15. Steam grades stronger under the heavily curtailed operations.



Bituminous—Conditions in the New York soft-coal market have seldom been worse in the mid-winter season than is now the case. It is simply a condition where there is no business whatever to negotiate. So far as quotations go, the true condition of the market is not adequately reflected in the prevailing price level, producers having consistently maintained a relatively profitable figure in spite of adverse conditions. It seems to be the feeling that with no buyers in the market, nothing would be gained by attempting to force the market with concessions. This applies particularly to the better grades, which are always the last to suffer in a depressed market. Only occasional reports of consignment coal on demurrage are heard, but there is probably more of this than is generally thought.

Contract business is the mainstay of the market at the moment. The larger companies in particular report a fairly good movement in this line, but others state that there are many suspensions. The possibility of labor troubles is having a tendency to increase the requisitions in order to accumulate some surplusses. However, most consumers as a rule are heavily stocked up and not many are prepared to take in more coal.

We continue to quote the New York market weak, but unchanged as follows: West Virginia steam, $2.60@2.75 good grades of Pennsylvania, $2.75@2.85; best Miller Pennsylvania, $3.10@3.20; George's Creek, $3.15@3.25.

Anthracite—Further adverse developments in hard-coal continue to be reported. Conservative members of the trade look for a general recession on individual coal, by the middle of the current month, down to the Apr. 1 circular. Such a slump usually occurs about Mar. 15, but it is clear to all that the circular will not be maintained that long this season.

As a result of the curtailed production, the supply of steam grades is not up to the requirements, there being a particular shortage of No. 2 buckwheat. A further curtailment in mining operations will tend to cause a relatively firm price situation in this department. The reserve supply of finer grades has all been picked up, while some of the companies are now finding it necessary to put some of the prepared sizes back into storage.

The domestic grades are all in heavy over-supply, dealers being so full up that they are unable to take any additional tonnage in spite of the attractive offers made. Concessions on the regular circular of 15 to 20c. per ton are readily obtainable on all the prepared sizes, and there are many individuals who would doubtless quote the full April circular on all-rail orders. As a rule, the independents are not as yet restricting mining but operations of the big companies have seldom been so curtailed, the Lehigh Coal & Navigation, Reading and Susquehanna collieries all closing down Wednesday for the balance of the week.

We quote the New York market for hard coal off on the domestic grades, but with the steam sizes a trifle stiffer as follows:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.00	$4.60@5.00	$5.05	$4.55@4.95
Egg	5.25	5.00@5.25	5.30	4.75@5.20
Stove	5.25	5.05@5.25	5.30	5.00@5.20
Chestnut	5.50	5.25@5.50	5.55	5.20@5.45
Pea	3.50	3.50	3.50	3.45
Buckwheat	2.75	2.75@2.85	2.70@3.45	2.25@2.70
Rice	2.25	2.25@2.35	1.95@2.20	1.85@2.20
Barley	1.75	1.75@1.80	1.70	1.50@1.70

PHILADELPHIA

Hard coal outlook unfavorable. Difficult to move the production even under restricted operations. Prices on domestic quoted down to the April circular. Bottom point in soft coal not yet reached.

Coal dealers, both wholesale and retail, still regard the outlook pessimistically. The past week has been anything but propitious. Summer weather so closely follows a little lowering of the thermometer, that most of the householders take a chance, and this is reflected on the meager demand on the retailer. Curtailment of work at the mines still continues. Outside of the steam sizes, the operators are hard put to dispose of their output, even with the reduced mining; with the month of February well on its way, and predictions for continued warm weather, the prospect is not favorable. It is intimated that even some of the individuals contemplate a curtailment of production, which is something unusual.

The trade will not take coal they do not want, and with yards well stocked, even the inducement of April prices, does not always produce an order. The tidewater business is distinctly flat and the New England market is simply buying from hand to mouth, with the result that orders are coming in slowly. The dealers wait until they have enough orders in sight to dispose of a cargo, before placing a schedule, knowing that there will be little or no delay in its fulfillment.

The bituminous market is running the anthracite a close second. There is a feeling that the bottom of the market, as far as prices concerned, has not as yet been reached, and every inducement in the way of prompt deliveries and attractive prices, fails to land sufficient business to keep operations in full swing. Advances over last year's contract prices are not being considered; it will wind up the same as last year, when many of the large steam users shopped around for their supplies, rather than tying themselves up on contracts.

BALTIMORE

Improvement in business handled over the local piers. Demand light, and the general situation not promising. Warm weather still has its effect on anthracite trade.

Prices are considerably below what they were in February of last year, and the demand is not as brisk as was the case at that time. The best demand has been in the coastwise contract business. Shipments were noted both from the B. & O. piers at Curtis Bay and the Western Maryland piers at Port Covington. A large number of charters have already been announced for February loadings, in addition to the fleet of coal colliers that run regularly. Foreign business looks brighter, as not only South and Central America, but Europe, is in the market through this port.

Local demand for soft coal is light, and in fact the general state of the market is poor. Many leading industries are taking little or no fuel. Pennsylvania best grades are holding around $1.25, with lower grades at from 95c. to $1.10. West Virginia steam fuels are demanding about 90c. at the mines. The coal situation is weak, offerings of three-quarter being made in some instances as low as 75 cents.

CENTRAL STATES

PITTSBURGH, PENN.

Wage scale conference this week in Philadelphia. Difficulty in adjusting scale for two years beginning Apr. 1 may prove less than expected. Demand continues poor, with prices irregular. Connellsville coke slow, at practically unchanged prices; shipments increased.

Bituminous—The Pittsburgh district operators are sending to the wage scale conference in Philadelphia, arranged to begin Tuesday, February 3, W. K. Field, John A. Donaldson and Geo. W. Schluederberg, of the Pitttsburgh Coal Co., and W. W. Kiefer, W. A. Luce, J. H. Sanford, William Henderson and Michael Gallagher of independent coal companies. Ohio and Indiana will be represented at the conference, as usual, while Illinois will also this year be represented. The Illinois operators are understood to be less anxious than others to change the base of the scale to mine-run as they have already developed the system. Van Bittner, president of the Pittsburgh district miners' organization, will head the men in the wage conference. While for several months the opinion seems to have been that the wage settlement this year would involve a long controversy, there appears to have been a change of opinion in some quarters of late, whereby there are some predictions that only a short suspension will occur.

The local coal market has continued in an unsatisfactory condition, demand being limited and price cutting common. While it is possible that there may be some extra demand this month and next, to provide consumers with stocks against a possible cessation in mining, there is no evidence thus far of any such demand. Shipments against contracts with manufacturers are light, although there has been a slight improvement in steel mill operations, railroad consumption shows no improvement, and domestic demand is the poorest for many seasons, doubtless on account of the extremely mild weather. List prices, which are frequently cut, remain as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The coke market has been quiet, and inquiry for February is developing more slowly than was expected, from furnacemen who covered January requirements only. The prompt market continues to be quoted at $1.90, but there is ground for suspicion that consumers requiring a round tonnage can shade the figure materially for early shipment and it is possible that not much coke will be bought for the whole month. The contract market is dead, but remains quotable nominally at $1.90 to $2. Foundry coke is in fair demand, and is quotable unchanged at $2.40 to $2.65 for prompt and contract, though transactions are usually at near the lower limit.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ending Jan. 24 at 291,055 tons, an increase of 22,698 tons, and shipments at 290,586 tons, an increase of 25,802 tons.

BUFFALO, N. Y.

Activity in bituminous disappeared with return of mild weather. Trade discouraged and mines are running slowly with no apparent prospect of recovery. Anthracite very quiet. Furnace coke a little better.

Bituminous—The activity resulting from the colder weather was all lost as soon as it became mild again, and the dealers

have instructed the mines to shut off. It is not denied that the apparent consumption is better than early in January, but it is not good enough to keep the mines running at anything like full capacity. So long as the output was cut down by the car shortage, prices held up, but the mines will not restrict operations, even after so much trouble from over-production. Consumers, especially the railroads, are getting a big advantage this winter in their fuel cost.

There is again complaint of coal on track unsold, though not so much as when the December slump took place; reports from the mines are to the effect that the men are grumbling over short work, viewing the situation as some sort of a combination against them. At the same time the railroads are reporting better business as a rule, and certain officials predict a steady recovery. There is a good movement of contract coal, but spot sales have run down. The prices of bituminous are weaker than they were a week ago, being based on $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run and $2.10 for slack, with Allegheny Valley coal about 25c. lower.

Coke—There is no change in the price of coke and none is looked for right away, but so many furnaces have blown in since the first of the year that furnace coke is comparatively more active now than foundry. Quotations remain on the basis of $4.50 for best 72-hr. Connellsville foundry.

Anthracite—The slump in the weather has hit the anthracite trade harder than anything else, especially as the season is now getting so late and the April reduction less than 60 days off. Consumers say they are running fires as low as possible, only burning as much coal as they commonly would in October.

All anthracite mines are running slow and there is preparation here to resume loading into vessels in order to get rid of the surplus. There are reports of big piles of coal at all upper-lake ports, which will disappear only with the return of steady winter.

TOLEDO

Domestic demand much restricted by the warm weather. Circular fairly well maintained. Colder temperatures momentarily stimulated the market.

Continued warm weather has worked havoc with the local market. The slow demand for domestic coal is most unusual for this season of the year and the dealers are feeling it, although the demand for steam coal has kept quite close to normal. This is due in the main to the possibility of a shut-down of the mines. It is known that the railroads also are acting upon this conclusion and are storing large tonnages.

Despite the short demand prices have remained fairly stationary, although most coal offices have recorded sales below the circular. There has been little speculative attitude regarding the weather among the dealers and with thir bins full even the lowest prices fail to create interest. For this reason quotations have held pretty close to list. The cold temperatures recently proved a temporary stimulus to the trade.

According to latest reports the Hocking Valley Docks will be near completion upon the re-opening of navigation this spring. This dock with a capacity of 20,000 tons in 10 hr. will be a great factor in facilitating shipping.

Prices are quotable as follows:

	Pocahontas	Hocking	Jackson	Pomeroy	Massillon	Pittston	Cambridge
Domestic lump	$2.50	$2.00	$2.50	$2.25	$2.50	$1.40	$1.40
Egg	2.50	1.35	2.50	1.50	2.50	....	....
Nut	1.75	0.80	2.00	1.75	2.50	1.35	1.20
⅔ lump	....	0.90	....	....	....	1.30	1.20
Mine-run	1.40	1.10	....	....	....	....	....
Slack	....	0.65	....	....	....	....	....

COLUMBUS, OHIO

Continued unfavorable weather has weakened the coal trade still further. Demoralization may result unless some relief appears soon. Prices unsteady and the volume of business small. Large quantity of demurrage coal on Ohio markets.

The local trade is weak and unsettled, due principally to the continued mild weather. The demand for domestic and steam grades is lacking and there is an overstock of all kinds. Consequently prices have weakened materially, although the larger operators and shippers are making every effort to maintain the market.

Dealers stocks are large and they are not inclined to buy. Unless colder weather arrives soon, stocks of some dealers will certainly have to carry over until the coming season. In fact there is practically no demand for domestic grades and as a result, there is little price cutting resorted to in order to force the market.

The steam business has been more steady than domestic but even it has been weak. Practically no stocking is being done in anticipation of a suspension Apr. 1, but some is expected in February. All contracts which expire at this time are reported as being renewed on about the same basis as last year.

One of the worst features of the trade is the large amount of demurrage coal on the markets in Toledo and the Northwest; this affects the Columbus market materially. The coal is being disposed of at extremely low prices. The indications for a good lake trade next season are not good since reports show a large amount of coal on the docks of the Northwest. Unless colder weather comes there will be considerable to carry over.

Production has been rather slow in all fields. The Hocking Valley district reported about 40% of the average with many mines shut down completely. In Pomeroy Bend district the conditions are not much better, but the domestic fields are probably the worst sufferers as there is practically no demand for the domestic sizes. In Eastern Ohio the production is estimated at 45% of normal.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50 @ 1.45	.....	$1.50 @ 1.45	$1.50 @ 1.40
3-4 inch	1.35 @ 1.30	$1.20 @ 1.15	1.35 @ 1.30	1.35 @ 1.25
Nut	1.25 @ 1.20	.....	1.30 @ 1.25	1.25 @ 1.20
Mine-run	1.15 @ 1.10	1.10 @ 1.05	1.15 @ 1.10	1.15 @ 1.10
Nut, pea and slack	0.80 @ 0.75	.....	0.85 @ 0.80	0.80 @ 0.75
Coarse slack	0.70 @ 0.65	1.00 @ 0.95	0.75 @ 0.70	0.70 @ 0.65

CLEVELAND

Bargain prices quoted to move demurrage coal on track. The lake freights to Lake Michigan reduced to 30c. a net ton. The Lake Superior freight rate has been reëstablished at 30c. a net ton.

Short time in many Cleveland manufacturing industries, combined with weather that greatly reduced the demand for domestic coal, has put the local market at the lowest point in recent years. Mine-run seems to be the heaviest, having recently sold at slack prices. Some operators have coal that has accumulated four days demurrage and is likely to pay more before it can be moved.

Youghiogheny is being quoted at circular, but because of the low prices it is not coming into this market extensively. No. 8 coal has sold the last few days as follows: 1¼-in., $1.80@1.90; mine-run, $1.75@1.85; slack, $1.60@1.75. Middle district coals are bringing the same price as No. 8.

Retail dealers are so well stocked-up, they have shut off orders. The warm weather during the week ending Saturday had the effect on the retail consumers and domestic orders were postponed. At the low prices operators and jobbers have advised their customers to dock coal. There has been some docking so far and if the market shows an improvement considerable more storing will be done. The opinion is general that the suspension Apr. 1 will be more protracted than usual. As soon as the market shows a return to normal, buyers will lay in heavier supplies.

Lake Vessel Rates—The Milwaukee-Western Fuel Co., of Milwaukee, Wis., had quietly chartered vessel capacity to transport 1,300,000 tons of soft coal from Lake Erie ports to Milwaukee during the navigation season of 1914 at 30c. a net ton. Last year this company paid 35c. a ton, having come into the market after the bulk of the chartering was done. The C. Reiss Coal Co. contracted last year for shipment to Sheboygan, Wis., at 32½c. with a reduction to 30c. if the vessels were unloaded within 48 hr. after arrival at the port of destination. Chicago, Indiana Harbor, and Waukegan also paid 35c. As the Milwaukee-Western contracts are taken by several vessel owners, the general rate to Milwaukee and other Lake Michigan ports will be 30c. The contracts are for three years.

Following this announcement it became known that the Lehigh Valley Coal Co. had chartered vessel capacity to move between 500,000 and 600,000 tons of hard coal from Buffalo to Duluth-Superior, and to Milwaukee and other Lake Michigan ports at 30c. Simultaneously announcement was made that soft-coal contracts for close to 1,000,000 tons had been placed with vessel owners for Lake Superior delivery at 30c. Since then it has developed standing contracts, with a stipulation that the going rate shall be paid, have been approved on the 30c. rate. Altogether close to 5,000,000 tons of coal have been accepted by vessel owners for 1914 at the 30c. rate. The business is so well scattered and so large that it is not likely any changes will be made to the principal ports until fall when the late rush starts about Nov. 20.

With a gross lake movement of soft coal, including bunker coal, of 28 million tons in 1913, it is apparent that not more than 25% of the business for the coming season has been closed. In the hard-coal trade, which was 5 million tons last year, 90% of the lake freighting contracts are still to be drawn.

DETROIT, MICH.

Trade continues heavy in spite of severe storm. Orders n contracts restricted. Many cars on demurrage.

Bituminous—Although Detroit experienced one of the severest storms of the season, last week, it failed to relieve he pressure incident to the adverse conditions in the market. .s a result, there has not been much of an increase in the olume of business, and although mine prices seemed to be oderately well maintained, there are many reports of price utting. Steam business is considered slack all along the ine, and expiring contracts are being renewed at the same igures as last year.

Conditions in the domestic trade remain unchanged, large tocks still being the rule. Because of the adverse weather onditions, dealers have not been able to move the coal, and re naturally not disposed to do any further buying. Reorts state that there are approximately 500 cars of coal tanding under demurrage in the local yards, and the necesity for disposing of this is of course having an adverse ffect upon the situation. Generally speaking, the January rade is considered the worst for years. Even the requisiions on contracts have been materially reduced, which have roved the most discouraging feature of the situation.

The bituminous market is now quotable on the following asis:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump.	$1.25	....	$1.30	....	....	$2.25	$2.20
Egg.....	1.25	....	1.30	....	....	2.25	2.30
Nut.....	1.10	....	1.00	....	....	....	....
Steam lump....	1.05	....	....	....	....	....	....
6-in. lump.....	1.10	$1.00	0.90	$0.90	$0.90	....	....
Mine-run.....	0.85	0.90	0.80	0.80	0.80	....	1.25
Slack.....	0.90	0.90	0.75	0 85	0.85	....	....

Anthracite—The warm weather has had a still further depressing effect upon hard coal also. As with bituminous, here is considerable anthracite on demurrage, and it is stated that much of this is being offered at 50c. off the circular.

HAMPTON ROADS

Local conditions show little improvement. Demand light with ample coal on hand, but no further price cutting. Heavy losses at sea.

Owing to the dull market the movement of coal in Hampton Roads has been light during the entire week, although the arrival of bunker steamers was fair during the early part. The government has loaded two colliers at Lamberts Point, one of them taking about 12,000 tons and the other 4000 tons. Practically all of the coal moving has been run-of-mine, demand being almost entirely for this grade. Prices are the same as for several weeks, and although there may be somewhat of an accumulation in the railroad yards, the prospects are that there will be no cutting in prices.

Figures are not yet obtainable showing the dumpings for January, but these will be below the December figures. As usual the largest dumping will be made by the Norfolk & Western Ry. from Lamberts Point. This road is now operating their new pier, and while everything is not working as smooth as it is should several large vessels have been taken care of there, and good time made in their loading.

Vessels loading coal for foreign ports have cleared for Genoa and Naples, Italy; Bermuda; Barbadoes; Campana, Argentine Republic; Cristobal; Dakar, West Africa; Kingston, Jamaica, and Cerea, Brazil. Of coal shipped from Hampton Roads ports during January approximately 20,000 tons have been lost at sea.

LOUISVILLE, KY.

Some colder weather failed to relieve the market. Trade heavily loaded with coal obtained at bargain prices. Operations much restricted.

Some wintery weather has revived hope in the trade that there may yet be a demand for fuel. Following several days on which the temperature went as high as 70°, the thermometer took a sudden drop and there was a mild blizzard. But there is little chance that even this marked change in the weather will have much effect at this late stage of the season.

Even were the cold snap to last for several weeks, the more conservative dealers have little hopes of much better business, because the market is heavily loaded with coal purchased at bargain prices, and only a continued heavy demand can make much impression upon these stocks. That such a demand will be had seems unlikely, as purchasing will probably be from hand to mouth for the rest of the season. Half-time operations is the rule, while some are forced to suspend entirely, especially those having no contracts; and even these last are receiving stop orders.

The absence of any demand for domestic coal makes it almost impossible to quote prices. There has been no market, the few sales at extremely low prices being too few to establish such quotations as the market. On the other hand, the steam market has shown some signs of strengthening, the necessarily low output of the prepared grades having resulted at last in a short supply of screenings. Eastern Kentucky of the better grades is selling at 75@85c., and growing stronger, while western Kentucky can be had as low as 60c.

SOUTHERN AND MIDDLE-WESTERN

BIRMINGHAM

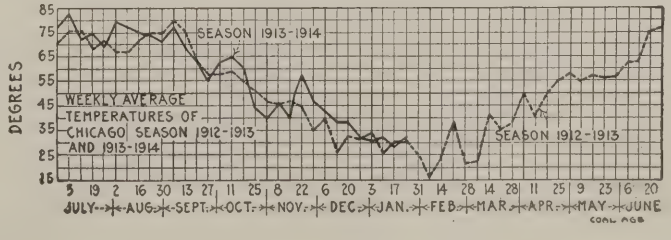
Practically the same conditions prevail on steam and domestic coal. Furnace and foundry coke quiet and blacksmith coal normal. Fairly good tonnage of pig iron booked. Car supply sufficient for demand.

There is little new in the coal market this week, as no change either way has been noticed, either in the volume of business or prices. Domestic coal is quiet, and many companies are curtailing their output, hoping to stimulate the price. Steam coal, while not in quite as stagnant condition as lump, is quiet, some of the large contracts specifying the minimum shipments for the time being.

The output is slightly larger at the present time than the demand, which has a tendency to weaken the market. Sales of blacksmith coal are reported in a satisfactory volume, a slightly larger tonnage being negotiated than last week. A fairly large tonnage of pig iron was booked by the furnaces, with prices about the same. The car supply seems sufficient for the present needs.

ST. LOUIS

Increased country demand resulted in slightly improved conditions, but market still heavy. Coal selling below cost. Larger shipments to West and Northwest.



There is a slight improvement in local conditions, but the average observer would scarcely notice it. Generally speaking, however, conditions are about as they have been for several weeks past. There has been some little demand from the North and West for coal moving through the St. Louis gateway, but locally nothing of importance has happened.

The low point has been reached on Carterville coal, when lump and egg sold for about $1.05 and Franklin County for $1.20. In the Standard district lump went as low as 80c. and at the same time screenings were bringing 45c.; this coal runs 70% lump and 30% screenings, which means a net price for the mine-run coal of 69½c., and it is absolutely impossible to produce coal for anything like that. Yet there is a large tonnage of it under demurrage at East St. Louis continually. In high-grade coal 2-in. screenings are weak at about 55 to 65c., and the washed sizes have also dropped off.

Anthracite is still coming in and is a drug on the market; the same applies to coke and smokeless. At one time in the month of January there was something like 30 cars of smokeless at East St. Louis, with several dollars demurrage on each car.

The market continues unchanged as follows:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump.....	.....	.....	.....	$0.90@1.00
3-in. lump.....	.....	.....	$1.40	.....
6-in. lump.....	$1.25 @ 1.50	$2.25	1.50	1.15@1.25
Lump and egg.....	1.85 @ 2.15	.....	.....	.....
No. 1 nut.....	1.15 @ 1.40	.....	.....	.....
Screenings.....	0.75 @ 0.80	.....	.....	.....
Mine-run.....	1.10 @ 1.20	.....	.....	.....
No. 1 washed nut.....	1.60 @ 1.75	2.25	1.60	.....
No. 2 washed nut.....	1.25 @ 1.35	.....	1.25	.....
No. 3 washed nut.....	1.15	.....	.....	.....
No. 4 washed nut.....	1.05	.....	.....	.....
No. 5 washed nut.....	0.50	.....	.....	.....

KANSAS CITY, MO.

More favorable weather has stimulated the demand and mines working good. Market is not steady, as a rule, and outlook is indeterminant and not encouraging.

The weather has been more favorable than at any time during the winter, though even yet it has failed to provide a consecutive stretch of low temperatures. In fact, the winter of 1913-14 will establish a precedent in the way of mild weather in the Southwest unless a marked change is seen in the near future. However, the operators of Kansas and Missouri have been quick to take advantage of the temporary stimulant, and are in most cases working from 70 to 80% capacity. Some others which hold railroad contracts of importance are running full time, although not producing as much coal as could be sold with more favorable weather conditions.

Demand for nut has been unusually strong recently. Lump, on the contrary, is moving slowly, and not at all in proportion to nut. Screenings, contrary to expectations, have been plentiful, the expected shortage failing to appear. The market has been steady. No change is likely in the face of the present weather, the situation not being one that can be helped by price concessions, according to operators.

OGDEN, UTAH

January was a weak month and market conditions have not improved. With exception of a few localities warm weather is prevailing throughout the territory. Surplus of nut and slack coal at the mines. Colorado mines working.

During January the operators in Wyoming and Utah were compelled to put the mines on a summer basis and large reductions in the force were made, some of the mines being shut down entirely. This condition was caused by a sluggish market, which could not be made active, although a few localities were visited by colder weather. All dealers have been carrying some stock and took advantage of the lower temperature to dispose of the surplus and consequently were receiving no shipments from the mines.

No doubt the market will not improve until all dealers have "cleaned up," at which time shipments will be resumed as the trade demands, which means on a summer basis.

Owing to small demand for lump coal, nut has been a drug on the market and most of the mines are carrying a surplus; slack coal is being unloaded with practically no demand.

Reports from Colorado show that the mines are working sufficiently to take care of the market and are having some idle days on account of the diminished demand.

Quotations remain unchanged:

	California	Nebraska	General
Lump	$3.00@3.50	$3.00	$2.75
Nut	2.50@3.00	2.00	2.25
Mine-run	1.85	1.85	1.85
Slack	1.00	1.00	1.00

PORTLAND, ORE.

Mild weather throughout Northwest cause of light demand for coal for domestic purposes. Conditions in general way unchanged.

The Pacific Northwest is enjoying an unusually mild and open winter and consequently the demand for coal for domestic purposes has been lighter than the average. There has scarcely been any freezing temperatures so far this winter in this district, and as the period for the coldest weather is past, the probability of having any is not very strong at this time. As a result, prices have not fluctuated here this winter, and there is little chance that they will advance. Keen interest is taken here in the passage of the Alaska railroad bill, as it is believed this will mean rapid development there, including coal.

PRODUCTION AND TRANSPORTATION STATISTICS

BALTIMORE & OHIO

The following is a comparative statement of the coal and coke movement over this road for December and the years ;1912 and 1913:

	December		Year	
	1913	1912	1913	1912
Coal	3,005,914	2,648,429	35,097,656	31,788,598
Coke	269,998	416,296	4,620,798	4,734,418
Total	3,275,912	3,064,725	39,718,454	36,523,016

COAL MOVEMENT

The following is a summary of the movement of coal and coke over 13 principal railroads during November and the first eleven months of 1913 in comparison with 1912, in short tons:

	November		Eleven Months	
Anthracite	1912	1913	1912	1913
Baltimore & Ohio[1]	166,263	171,714	1,433,485	1,398,652
Chesapeake & Ohio[1]	1,198	1,225	21,909	15,864
Erie[3]	654,757	732,726	6,857,482	8,016,552
Pennsylvania[1 3]	916,914	987,487	9,275,631	9,699,210
Virginia[2 1]	83	50	180	959

[1] Includes coal from connecting lines.
[2] Includes company's coal.
[3] Does not include company's coal hauled free.

Note.—The Southern Railway hauled 362,439 short tons of coal during October, 1913, and 3,495,721 short tons during the 10 months ending Oct.

FOREIGN MARKETS

GREAT BRITAIN

Jan. 23—There is a little more inquiry for admiralty large coals. Collieries who are well placed as regards tonnage, are holding for higher prices, but others in need of vessels, are accepting easier terms. Quotations are approximately as follows:

Best Welsh steam	$4.50	Best Monmouthshires	$4.17
Best seconds	4.38	Seconds	4.05
Seconds	4.26	Best Cardiff smalls	2.67
Best dry coals	4.38	Seconds	2.52

COAL SECURITIES

William J. Hoey reports the market on various coal securities for the week ending Jan. 31, as follows:

The First BARSTEEL Electric Mine Locomotive in the West

The illustration shows the first Baldwin-Westinghouse Barsteel Mine Locomotive in actual service in the West. After it had been given a thorough test at the mines the owner made the statement that he had been in the mining business for many years and had purchased all kinds of locomotives, but that this *Barsteel* type was the first one which entirely met his requirements.

The *Barsteel* frame on this 15-ton locomotive is exceptionally massive. It was made heavier in proportion than some of the lighter locomotives in order to bring it up to the desired weight, but the advantages of excellent ventilation for the motors, ease of inspection and accessibility of interior parts, were not sacrificed.

On this particular locomotive great strength is obtained at the journal boxes. Note how one of the massive bars passes between the bottom of the spring and the top of the journal box.

Full information about Baldwin-Westinghouse *Barsteel* Electric Mine Locomotives can be obtained by writing either company.

You Get Better Machinery—

Because the Manufacturer Advertises

The Weekly Ad-Talk Page

When a manufacturer advertises he has to come squarely out into the open and tell the public what he has.

If he does not, his advertising will not be a success.

Get out into the lime-light, yourself, and see what happens—you will begin to spruce up at once. You can't help it; it is just human nature.

Likewise the machine put into the lime-light. The manufacturer is bound to make it a better machine because he has put it into the open.

He can't advertise it successfully unless it has real merit and possesses real talking points. He cultivates the habit of selling by plain, open and above board methods. And the more he cultivates the habit, the better he makes his machine.

Then there's the competition of it. One manufacturer starts something—and tells all about it in his advertising. (And he is a wise man to do it, too. For if he tries to keep it "dark," his competitors will know all about it before it's on the market; but the buyers will know nothing of it.)

The other manufacturers refuse to give the entire market to the fellow with the improvements, so they come back with a machine to compete.

Who gets the benefit? Everybody—but *principally* you who read the ads!

We Originate the Good Features—Others Follow

In Jeffrey *ARMORPLATE* Locomotives

you will find all the *Distinctive* Features in Design and Construction.

Points of Service:

Safety First
Reliability
Accessibility
Maximum Capacity
Minimum Upkeep

Construction Points:

Armorplate Frame.

Allows the greatest per cent. of weight to be used for motor equipment for a given weight of locomotive.
Gives absolute protection to motorman and equipment.
Surface of frame is plain and smooth.
Cost of upkeep is a minimum.

Large Capacity Ball Bearing Motors.

Of ample power to slip the wheels continuously without overload to any part.

Eliminate bearing wear on armatures (the most troublesome and expensive factor in locomotive maintenance.)

WHY COAL MINING COMPANIES USE THE SMITH HAND BATCH MIXER

Economy Because it mixes perfect concrete quickly and economically. With a Smith Hand Mixer you can cut the cost of shovel-mixed concrete in half and secure an A-1 mix which will pass the most rigid inspection.

Portability Because it is a light, compact *batch* mixer. Weighs only 1000 lbs. It can be used either above ground or run into the mine cage and lowered down into the mine itself. Concrete repairs in the different workings should be made permanent with a Smith Hand Mixer.

Capacity Because of its large capacity. Three slow easy turns of the drum mixes a batch of $2\frac{1}{2}$ to 3 cu. ft. of concrete. Four men and a Smith Hand Mixer will easily turn out 30 to 35 cu. yds. of concrete per day.

Coupon Because they secured our special Smith Hand Mixer Booklet No. 20-R, and proved to their own satisfaction that this machine would prove a profitable investment. Will gladly refer you to a number of Coal Mines where the Smith Hand Mixer is being used. FILL OUT COUPON and get a copy of our BOOKLET No. 20-R.

MAILING COUPON

COAL AGE

Vol. 5 NEW YORK, FEBRUARY 14, 1914 No. 7

The Surprise

By Berton Braley

Written expressly for Coal Age

"That pit-boss gets my goat for fair,
I hate his face an' his auburn hair
An' the way he looks an' the way he walks
An' the kind of bunk that he always talks;
If he slips me much of his funny gab
I'll poke him quick with an awful jab!"

The miner paused in his talk a bit,
While his pipe he filled and packed and lit,
"There's some," he said, "that's workin' here
Who holds the boss in deadly fear,
An 'Yessir' an' 'Nossir' is all they say
When his nibs comes flockin' around their way:
But say—if he ever gets fresh with ME
I'll show him the kind of a guy I be,
He can't get flossy with me, that's flat,
I'll show him the place to head in at,
For I knows my work an' I does it good,
As good as a pit-boss ever could,
An' if one of them guys gives me a call
I reads him the riot act, that's all,"

"Hey you!" said the Boss as he came along,
"You're drillin' them holes of yours all wrong,
You're a blankety fool of a blankety blank
With nuthin' but mud in your thinkin' tank!
If you had the sense of a ring-tailed ape
You'd have that job in decent shape
But—"a hairy fist with a vicious clout
Came hurtling over and put him out,
And the miner said, with a pleasant smile,
"You get me, Stephen?—well, that's my style,
You can't get funny with me, because
I'm just as tough as I said I was!
I handed his to that loud-voiced slob,
An' now it's me for another job!"

That's not the way you thought 'twould end?
I'm sorry, but truth is truth, my friend!

The Stripping of Anthracite

By E. G. Lewis*

SYNOPSIS—A large area of the anthracite region of Pennsylvania may be successfully worked by stripping with modern steam shovels. The maximum amount of overburden which may be handled per ton of coal is about 4 cu.yd. Full revolving machines of small size may often be advantageously used for loading the coal into mine cars.

Although most of the coal from the anthracite region has been in the past, and doubtless will be in the future, secured by underground working, there are certain places where, by the use of suitable machinery, open strip pit mining may be carried on to advantage. The introduction of the modern steam shovel into this class of work has made it possible to strip from 40 ft. to 200 ft. of overburden in order to uncover from 4 ft. to 30 ft. of coal, the maximum ratio being about 4 cu.yd. of stripping to 1 ton of coal.

By no means all of the anthracite district is within the limit of stripping possibilities, the coal in most places being too far below the surface. This is true of the district in and around Wilkes-Barre and Scranton and north of Carbondale. However, the region included in the area from Hazleton west to Shenandoah, Mahanoy City, Centralia and Mount Carmel, southeast to Pottsville, Tamaqua and Lansford, and north to Drifton and Jeddo, is largely a stripping proposition.

At the present time, most of the stripping is done on contract for the coal companies. Among the larger stripping operations are those of N. J. Cuyle & Son, of Hazleton, who strip for the Lehigh Valley Coal Co., the Central Penn Quarry & Stripping Co., of Harleigh, Penn., employed by G. B. Markle, and the A. E. Dick Construction Co., of Mount Carmel, stripping for the Philadelphia & Reading Coal & Iron Co.

A Typical Stripping Operation

A description of the last named job may be of interest, since it is typical of all the others. The coal lies in a saucer-shaped basin, as indicated by the accompanying drawing. The shovel is started in on about a 10-ft. cut which allows of loading into dump cars on a track laid along the original surface of the ground. This cut is taken all the way through the work, which, in the above case, is a distance of about two miles. The second through cut is taken at a depth of about 20 ft., the loading track being shifted to the bottom of the first lift taken out.

Fig. 1. A Strip Pit near Mt. Carmel

It should be here added by way of explanation that it is only possible to take a cut of about 10 ft. and load into the standard dump car stationed on the bank alongside. On the second through cut, however, as may be seen in the sketch, loading is being done upon the same level as the shovel track and the depth of the cut is limited only by the depth at which it is possible to drill and shoot advantageously.

The second cut is carried all the way across the work, which, in this case, is about 1000 ft. This level is maintained for reasons of getting good drainage and securing a low grade for the track to the dump. It is usually possible to get to the dump from the first cut on a grade of about one-half per cent. This increases as the shovel works down deeper, the maximum sometimes being 10 and 12 per cent., in which case an incline and engine are used to haul the whole train, including locomotive, to the dumping ground.

The standard equipment on the above stripping job includes a 70-C Bucyrus shovel weighing about 85 tons

*50 Church St., New York City.

FIG. 2. A SMALL FULL-REVOLVING SHOVEL LOADING COAL

FIG. 4. A SMALL SHOVEL MOUNTED ON WIDE-TIRED WHEELS

and provided with a dipper of 2½ cu.yd. capacity. This is mounted on railroad trucks and is self-propelling, which allows the machine to move ahead as rapidly as the material is taken out. Shovels of this type handle from 20,000 to 35,000 cu.yd. per month. The dirt train equipment is made up of 4-cu.yd. Western dump cars hauled by an 18-ton Vulcan locomotive. From 6 to 12 cars make up a train until the steep grades are encountered, when it is found necessary to diminish the number of cars in a trip considerably.

The accompanying photograph, Fig. 1, shows a portion of the A. E. Dick contract at Mt. Carmel, as described above. This picture gives a good idea of the work and its magnitude, as well as the method of procedure. The

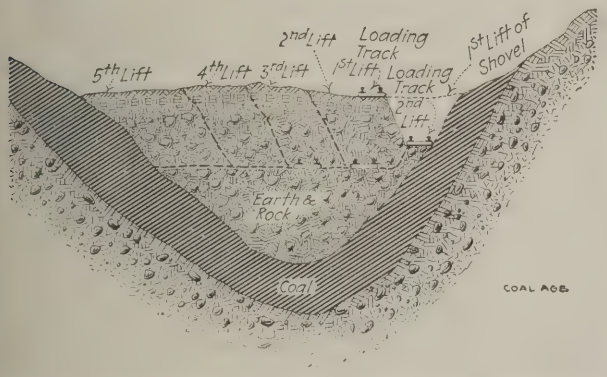

FIG. 3. CROSS-SECTION OF A STRIPPING OPERATION

shovel can be seen taking its third cut on the second lift, shown in the line drawing, Fig. 3, as lift No. 4.

SMALL SHOVELS LOAD COAL

The small revolving steam shovel has also been successfully introduced into the coal regions for the purpose of loading the stripped coal, working in culm and slate banks, ditching, etc. In coal loading, these machines have been found to decrease the cost about one-half. They also give a much better product, inasmuch as it is not necessary to break the coal up to sizes which a man can lift, as is the case in hand loading. Furthermore, it is possible to top off the cars, thereby adding about 20 per cent. to their capacity.

These shovels are full revolving and mounted on railroad trucks, of the same gage as the mine tracks. This makes it possible to shift the machine from one part of the work to another at little cost, it being self-propelling. Shovels of this type weigh about 25 tons, and carry ⅞-cu.yd. dippers.

One of the interesting operations wherein this type of machine is employed is that of the Lehigh & Wilkes-Barre Coal Co., at Green Mountain. This is shown in Fig. 2. Here the coal-loading track is maintained alongside of the shovel, while a third track is laid up to the rear of the machine, upon which an empty car is kept. Into this is loaded any rock or slate encountered during the work, thus preventing its going to the breaker or necessitating the process of picking from the car by hand. The shovel runner soon becomes quite expert in

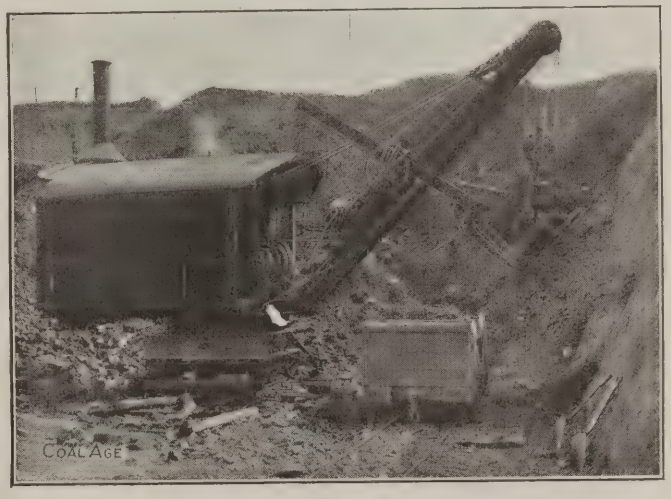

FIG. 5. A SMALL SHOVEL AT WORK NEAR HAZLEBROOK

the matter of segregating the slate from the coal.

In this work some extremely good records have been made. One report of a 9-hr. day shows that 96 cars of coal and 45 cars of slate were handled. These cars held 102 cu.ft. each, making a total for the nine hours of about 423 tons of 2240 lb.

Anthracite Production in Seventeenth Pennsylvania District

The total output of hard coal in the seventeenth district of Pennsylvania for 1913 amounted to 4,324,561 tons. The total number of men employed was 8540. The greater part of this coal was produced by the Lehigh Coal & Navigation Co., operating mines in Carbon and Schuylkill counties. The average number of days worked was 263. Of the total production, 521,495 tons was used at collieries and 132,060 tons sold to local trade.

A Draw-Out Mining Switch Pillar

Special Correspondence

SYNOPSIS—A switch especially designed for use underground. It is built in units of various capacities and any number of sections may be joined together, forming a continuous board.

One of the most frequent causes of accident from electrical apparatus in mines is due to the improper handling of switch gear, in spite of good design. With the class of electrical installation which is usual in collieries, it is by no means an easy matter to be sure that a cable is thoroughly and effectually free from potential. It will be easily seen that where the supply voltage is fairly high, accidents may easily arise through workmen handling conductors under the impression that they are free from potential, when such is not the case.

Mining work necessarily involves certain special conditions, to meet which great care in design and construction is necessary. In order to meet the special circumstances surrounding underground operations, Messrs. Switchgear & Cowans, Ltd., of Manchester, England, have installed a new type of switch pillar in some important collieries. The chief principles upon which this switch gear is constructed will be noted from the photographic illustration of a single unit, shown in Fig. 1, a switchboard seen from the back, made up of several units, shown in Fig. 2, and a cross-sectional elevation of the typical arrangement illustrated in Fig. 3.

The switch itself is inclosed in a strong cast-iron case built up in three sections. The middle section supports the whole of the mechanism, and is the portion which travels on steel rollers carried in runways which support the switch and faciliate the movement either inward or outward. The upper section consists of two parts, and is made in two styles. In a simple case, for which no isolating switches are required, this top portion is in one piece, and forms a cover which is bolted to the middle section. In the case of a true mining switch, however, namely, one with isolating plugs interlocked, the upper section consists of two castings, one being a back plate containing the necessary switch plugs, and the other the cover, which is bolted both to the back plate and to the middle section.

The back plate also carries on the side remote from the cover a cast-iron trunk, which slides within a second trunk attached to the busbar chamber. The object of these two trunks, the one sliding within the other, is to protect the plugs during withdrawal. The lower section consists of a tank, which is of cast iron, strengthened by external ribs. The middle, top and lower sections are bolted together through wide machined flanges, fitting sufficiently tight to make them practically dustproof.

It has been found by experiment that the rise in pressure due to an explosion of gas within the cast-iron box is in the neighborhood of 60 to 80 lb. per square inch.

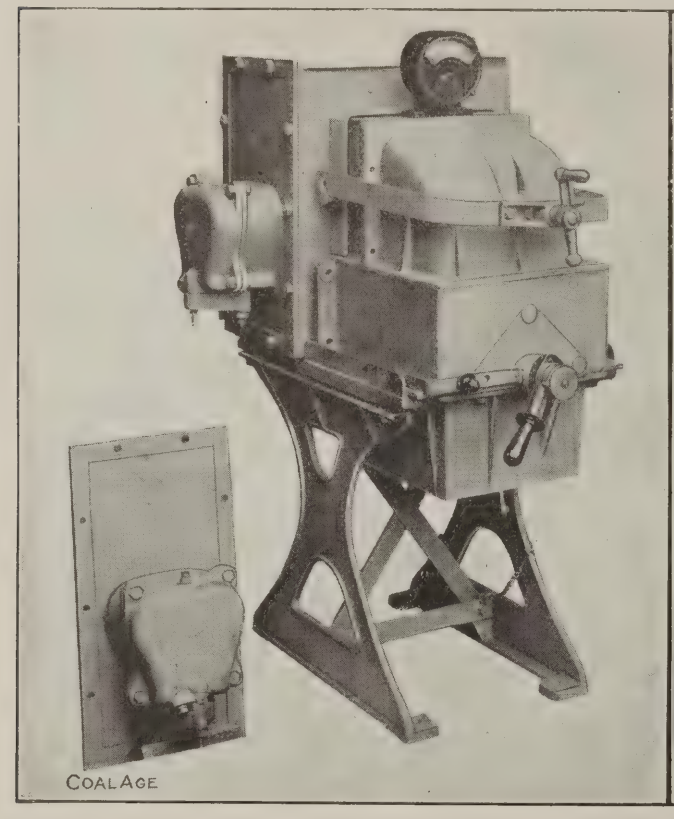

Fig. 1. Rear View of a Single Unit

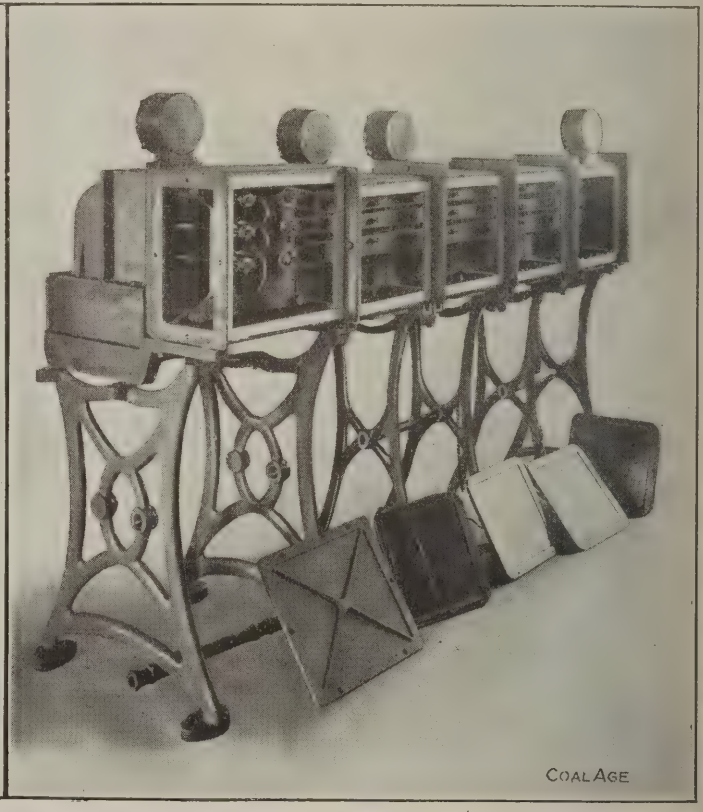

Fig. 2. Several Units Joined Together, Forming a Switchboard

The cases of these mining switches are therefore constructed to safely withstand a pressure of 160 lb. per square inch, giving a sufficient factor of safety.

The joints are, as stated above, machined. This does not mean that they are gastight, but it has again been determined by experiment that the gases from an explosion are sufficiently cooled in passing between flanges of considerable width to prevent the possibility of their firing other gases outside the case. The principle adopted, therefore, is that gases may accumulate within the case, and may be exploded without igniting explosive gases existing in the neighborhood of the switch.

The voltages in use in Great Britain are classified in two main ranges, one up to 500 volts, and the other up to 3000 volts, the lower being termed medium-pressure and the latter high-pressume transmission systems. Above 300 volts potential the manufacturers mentioned prefer to go to the cabinet type of drawout switch, which does not lie within the range of the present article.

Confining ourselves for the moment to the drawout pillars, as shown in the illustrations, the medium-pressure type is made in three sizes; namely, 100, 300, and 750 amperes capacity, while a smaller size for 70 amperes is now in process of standardization.

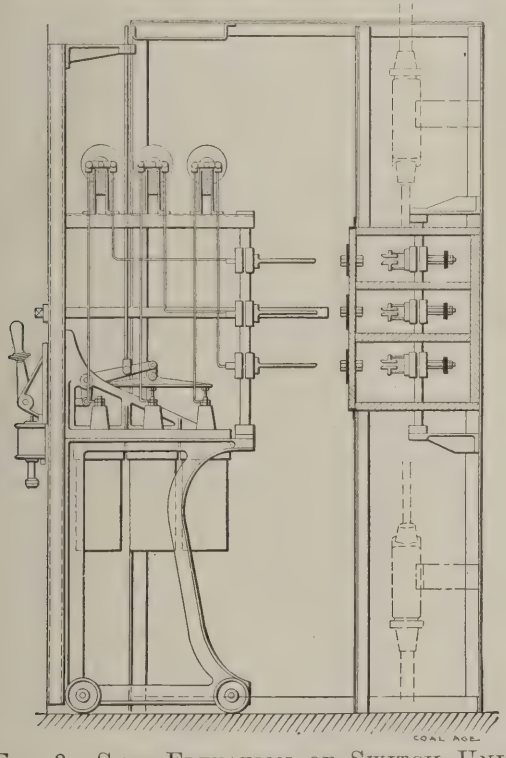

FIG. 3. SIDE ELEVATION OF SWITCH UNIT

Turning to the construction of the switch itself, each has three laminated bow-shaped brushes with an ample head of oil above them. These contacts are controlled by both overload and no-load trips. It is also impossible to forcibly hold the switch in when an overload is passing. An indicator is provided to show the position of the switch independent of the handle, and interlocks are furnished so that it is impossible to push the switch into its socket when closed, and equally impossible to withdraw it from the socket when it is in a similar position.

All the various sizes have been so designed that they bolt up to one another to form a switchboard. The busbars, as will be seen in Fig. 2, are contained in a rectangular case, running behind the plugging gear. Both inlets and outlets enter the busbar chamber direct, and hence any disconnecting has to be done when the switch is removed for inspection or repair.

It will be seen that the busbars are arranged at the top of the busbar trunk, the bottom half being therefore available for connecting the cables and sockets direct. With a feeder switch, for example, the upper sockets are connected direct to the three busbars and the lower sockets to the three cables. With the switch plug a complete control is exercised both by hand and automatically.

Fig. 2 shows a number of units arranged in the form of a switchboard, the cast-iron legs being so proportioned as to allow of uniform grouping irrespective of the size of individual units of which the group is composed. In such a board a spare busbar section may at any time be included for the purpose of mounting instruments, such as a synchronizer, voltmeters, power-factor indicators, wattmeters, and similar instruments. The best location for a section of this kind is usually about the middle of the assembled board.

A large number of these switches have been installed in the South Wales coal field, where the conditions of operation are severe. Other localities in England and Scotland have also utilized this switch. It, therefore, forms a useful example of the way in which some of the difficulties attendant upon the electrical operation of collieries have been overcome.

Accident Increase in Bituminous Mines of Pennsylvania

The following letter has been sent to all the bituminous mine inspectors in the State of Pennsylvania by the chief of the department of mines:

I beg to submit to you and to all the other inspectors comparative statistics of accidents in the bituminous mines for the years 1912 and 1913. The results in many of the districts are disappointing. The number of inspectors having been increased and the number of mines allotted to several of them having thereby been considerably decreased, it was reasonable to look for a better record for 1913, but instead of that, there has been a large increase in fatalities.

I shall expect an explanation as to the cause for the great increase in accidents from falls, cars and electricity. Some districts show a creditable record, but it is not necessary to name either those whose records are bad or good; the statistics herewith will show each inspector where he stands.

Serious disasters such as the explosion at the Cincinnati mine will occur occasionally, but why the accidents from falls should increase from 249 in 1912 to 313 in 1913, a difference of 25 per cent., and the accidents from electricity from 18 to 23, a difference of 27 per cent., is hard to understand.

I desire in this connection to impress upon you the necessity of keeping constantly on the alert to see that all the mine officials as well as the mine workers observe the provisions of the law relating to safety. Not only must dangers from gas and dust be avoided and guarded against, but the workers must be impressed more forcibly with the necessity for greater care in standing timber and in taking down the roof and coal and in riding on or being about the mine cars, and they must be particularly cautioned to avoid contact with electric wires or other mediums through which fatal shocks may be conveyed. If you can lessen accidents from these causes, much will be accomplished.

It is scarcely possible for many districts to make as good a showing as the 3d, 4th, 8th, 10th, 18th, 27th and 28th districts were fortunate enough to make during 1913, as these, owing to favorable conditions, always make good records; but in the other districts the inside accidents should be greatly reduced. The statement herewith shows that several of the acknowledged dangerous districts had but comparatively few accidents.

Kindly acknowledge receipt of this letter.

Very truly yours,

JAMES E. RODERICK,
Chief of Department of Mines.

ACCIDENTS, BY DISTRICTS, IN THE BITUMINOUS MINES OF PENNSYLVANIA, 1912 AND 1913

First District—A decrease of 50 per cent. in accidents by falls, 33 per cent. by cars and 50 per cent. by electricity.
1912—By falls, 14; by cars, 6; by electricity, 2.
1913—By falls, 7; by cars, 4; by electricity, 1.

Second District—An increase of 33 per cent. in accidents by falls and 25 per cent. by cars. No accidents by electricity.
1912—By falls, 22; by cars, 4; by electricity, 1.
1913—By falls, 28; by cars, 5; by electricity, 0.

Third District—A decrease of 14 per cent. in accidents by falls. No accidents by cars.
1912—By falls, 7; by cars, 3.
1913—By falls, 6; by cars, 0.

Fourth District—An increase of 300 per cent. in accidents by falls.
1912—By falls, 2; by cars, 2.
1913—By falls, 8; by cars, 2.

Fifth District—A decrease of 40 per cent. in accidents by falls and 60 per cent. by cars.
1912—By falls, 10; by cars, 5.
1913—By falls, 6; by cars, 2.

Sixth District—A decrease of 7 per cent. in accidents by falls and 80 per cent. by cars. Two accidents by electricity.
1912—By falls, 14; by cars, 7.
1913—By falls, 13; by cars, 1; by electricity, 2.

Seventh District—An increase of 16 per cent. in accidents by falls and 50 per cent. by electricity.
1912—By falls, 6; by cars, 6; by electricity, 2.
1913—By falls, 7; by cars, 6; by electricity, 3.

Eighth District—A decrease of 25 per cent. in accidents by falls.
1913—By falls, 3; by cars, 0.
1912—By falls, 4; by cars, 0.

Ninth District—A decrease of 10 per cent. in accidents by falls. An increase of 100 per cent. by cars. No accidents by electricity.
1912—By falls, 10; by cars, 3; by electricity, 1.
1913—By falls, 9; by cars, 6; by electricity, 0.

Tenth District—A decrease of 57 per cent. in accidents by falls and 50 per cent. by cars. One accident by electricity.
1912—By falls, 7; by cars, 2; by electricity, 0.
1913—By falls, 3; by cars, 1; by electricity, 1.

Eleventh District—An increase of 33 per cent. in accidents by falls and 150 per cent. by cars. No accidents by electricity.
1912—By falls, 9; by cars, 2; by electricity, 1.
1913—By falls, 12; by cars, 5; by electricity, 0.

Twelfth District—An increase of 44 per cent. in accidents by falls. Two accidents by cars.
1912—By falls, 9; by cars, 0; by electricity, 1.
1913—By falls, 13; by cars, 2; by electricity, 1.

Thirteenth District—An increase of 40 per cent. in accidents by falls. A decrease of 50 per cent. by cars. No accidents by electricity.
1912—By falls, 5; by cars, 6; by electicity, 2.
1913—By falls, 7; by cars, 3; by electricity, 0.

Fourteenth District—An increase of 66 per cent. in accidents by falls and 100 per cent. by cars. One accident by electricity.
1912—By falls, 6; by cars, 3; by electricity, 0.
1913—By falls, 10; by cars, 6; by electricity, 1.

Fifteenth District—An increase of 20 per cent. in accidents by falls and 50 per cent. by cars.
1912—By falls, 10; by cars, 4.
1913—By falls, 12; by cars, 6.

Sixteenth District—An increase of 90 per cent. in accidents by falls. A decrease of 33 per cent. by cars.
1912—By falls, 10; by cars, 12.
1913—By falls, 19; by cars, 8.

Seventeenth District—An increase of 70 per cent. in accidents by falls and 100 per cent. by cars.
1912—By falls, 7; by cars, 2.
1913—By falls, 12; by cars, 4.

Eighteenth District—A decrease of 25 per cent. in accidents by falls. Two accidents by electricity.
1912—By falls, 8; by cars, 0; by electricity, 0.
1913—By falls, 6; by cars, 0; by electricity, 2.

Nineteenth District—A decrease of 28 per cent. in accidents by falls. An increase of 100 per cent. by cars and two accidents by electricity.
1912—By falls, 21; by cars, 3; by electricity, 0.
1913—By falls, 15; by cars, 6; by electricity, 2.

Twentieth District—An increase of 80 per cent. in accidents by falls and 100 per cent. by cars.
1912—By falls, 10; by cars, 2.
1913—By falls, 18; by cars, 4.

Twenty-first District—An increase of 110 per cent. in accidents by falls and 50 per cent. by cars. A decrease of 66 per cent. by electricity.
1912—By falls, 9; by cars, 8; by electricity, 3.
1913—By falls, 19; by cars, 12; by electricity, 1.

Twenty-second District—An increase of 100 per cent. in accidents by falls and 100 per cent. by cars. No accidents by electricity.
1912—By falls, 5; by cars, 1; by electricity, 3.
1913—By falls, 10; by cars, 2; by electricity, 0.

Twenty-third District—An increase in accidents by falls of 14 per cent. A decrease of 44 per cent. by cars. One accident by electricity.
1912—By falls, 7; by cars, 9; by electricity, 0.
1913—By falls, 8; by cars, 5; by electricity, 1.

Twenty-fourth District—An increase of 23 per cent. in accidents by falls. A decrease of 33 per cent. by cars. Three accidents by electricity.
1912—By falls, 13; by cars, 6; by electricity, 0.
1913—By falls, 16; by cars, 4; by electricity, 3.

Twenty-fifth District—An increase of 40 per cent. in accidents by falls and 100 per cent. by electricity.
1912—By falls, 15; by cars, 4; by electricity, 1.
1913—By falls, 21; by cars, 4; by electricity, 2.

Twenty-sixth District—An increase of 44 per cent. in accidents by falls. A decrease of 66 per cent. by cars. An increase of 200 per cent. by electricity.
1912—By falls, 9; by cars, 6; by electricity, 1.
1913—By falls, 13; by cars, 2; by electricity, 3.

Twenty-seventh District—This is a new district. Seven lives were lost by falls and 1 by cars.

Twenty-eighth District—This is a new district. Five lives were lost by falls and 1 by cars.

A New Anthracite Mine Inspectors' Board

The appointment of a new board of mine inspectors' examiners by the court of Luzerne County is thought by mine workers to purpose the end of the alleged system of former boards. It was charged that they passed just enough men to fill the vacancies existing, in order to settle who should fill the positions without the necessity of an election. There have been various candidates for the office of Inspector of Mines in past examinations, but at each election it has developed that there were just the necessary number of eligibles to fill the ballot. The claim was made that this system showed favoritism, and so many complaints were made that the court appointed an entirely new board. This board is composed of George P. Gallagher, of West Pittston, assistant division superintendent for the Lehigh Valley Coal Co.; Charles S. Miles, of Wilkes-Barre, consulting engineer; Benjamin McEnany, of Exeter; Thomas J. Evans, of Nanticoke; and Patrick Dougherty, of Lansford, practical miners.

Decrease in Fatalities in West Virginia

The Department of Mines, of West Virginia, has completed its compilation of the fatality record for 1913. The record shows a decrease of about seven per cent. in spite of an increase of seven per cent. in the number of men employed. The total number of fatal accidents was 335 as against 359 in 1912, a decrease of 24. The miners employed now number 73,251 as against 68,248 in 1912, an increase of 5273.

The months of March and August lead in the death list with 34 each, while April, with 22, makes the best showing. The monthly record is:

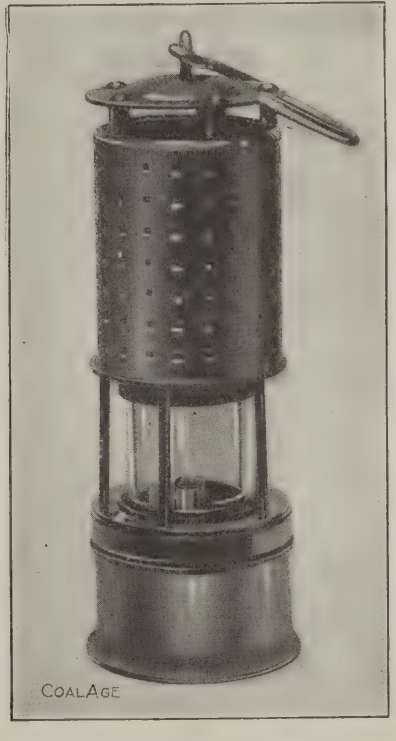
FATALITIES BY MONTHS IN WEST VIRGINIA 1913

January	29	July	28
February	33	August	34
March	34	September	26
April	22	October	25
May	28	November	26
June	24	December	26

It is interesting to note that 109 of the 335 fatalities, or almost one-third, were due to the carelessness of the

victims, themselves, and should have been avoided. If they had not occurred, the fatality count would have been 226, the lowest since 1905, when it was 212.

A recapitulation of the fatalities, when classified as to causes, shows that 204 of the 335 were due to falls of roof and coal; 87 were the result of transportation mishaps; only 8 were caused by explosions, this number being a new record for the state; 8 were due to machinery; 16 to electrocutions, and 12 had miscellaneous causes, such as falling down shafts, kicks by mules and the like.



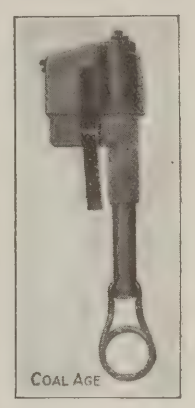
The death rate for each thousand men, employed in 1913, was 4.55, a decrease of 0.61 from 1912, when it was 5.26. This is the best rate since 1905. The rate from 1905 to 1913, inclusive, follows:

MINING DEATH RATE IN WEST VIRGINIA, 1905-1913

1905	4.38	1910	4.79
1906	5.44	1911	5.24
1907	12.43	1912	5.26
1908	5.43	1913	4.55
1909	6.06		

The Koehler Safety Lamp

This lamp is designed after the pattern of the well known Wolf lamp, the patents of which have expired. The design of the lamp is a general improvement on the former type. It is claimed that nothing short of deliberate carelessness on the part of the lampman or the user of the lamp can make the same unsafe.



THE KOEHLER NAPHTHA SAFETY LAMP

One of its chief features is the simplicity of its construction, embodying also the features of strength durability and security. The lamp consists of but 12 parts, counting all the separate pieces of the lamp, chimney and igniter. These parts are well fitted together, and the general workmanship of the lamp is as nearly perfect as it is possible to make it.

The lamp is designed to burn naphtha, which is absorbed and held in the cotton, within the oil vessel of the lamp. The oil vessel is of compressed steel, with a brass top, securely brazed thereto. The chimney consists of a 2¼x2¼-in. Macbeth glass, surmounted by a double-gauze chimney, provided with a steel spring washer to hold the gauzes tight against the glass. In the upper portion of the chimney, the gauzes are further protected by a pressed-steel bonnet, which is secured to the lamp ring below the glass by five brass standards. The lamp vessel is secured in the lamp ring by a screw-plug lock or an electric magnetic lock, as desired. Also, when desired, the steel bonnet of the lamp is omitted. The lamp complete weighs 2 lb. 15 oz. to 3 lb. 4 oz., according to its fittings. The height of the lamp is 10 in.

The Koehler lamp is manufactured by the Koehler Manufacturing Co., Marlboro, Mass., at a price less than that previously paid for lamps of a similar type. The lamp has already been adopted by 48 companies and is designed for use as a lamp for general mine work, as well as a lamp for testing for gas. There are different models or styles adapted to these different uses. Model No. 7, with a 3¼-in. glass, has a height of 12 in., and is adapted for use in ship holds, coal bunkers, oil refineries, and as a lamp for night watchmen in factories and mills. The "pyro" igniter, used in this lamp is one of the best designs. The cartridge is easily replaceable and throws a spark horizontally that never fails to ignite the wick. The lamp gives a steady light of 1.6 cp. for 18 hr., which, it is claimed, is 70 per cent. greater than that of any other safety lamp of a similar type.

THE KOEHLER PYRO IGNITER

The Koehler Manufacturing Co. also supply electromagnets for opening the Koehler and the Wolf lamps, lamp-filling apparatus, lamp-cleaning machines and complete outfits for lamp cabins; and carry, besides, a large stock of safety-lamp glasses for all types of lamps.

Pennsylvania Mine Foremen's Examinations

At a conference of nine anthracite-mine inspectors, with superintendents and expert miners, 32 in all, representing the collieries and washeries in Schuylkill, Carbon, Dauphin, Northumberland and Columbia Counties, held at Pottsville, it was decided to hold the annual examination for elegibility as mine foreman and assistant mine foreman, at Pottsville, on April 3. It is expected that there will be about 200 applicants to take the examinations.

BY THE WAY

A mine mule don't kick accordin' to no rule.

It takes a heap of licks to drive a nail in the dark.

Nothing is so new as what has long been forgotten.

No man should think to cast a shadow like an elephant.

It frequently happens that one murder makes a villain, millions a hero.

You may be a hammer today, but perhaps tomorrow, you may be the anvil.

It is not easy to straighten in the oak the crook that grew in the sapling.

The Vancouver Island Strike Anomaly

Special Correspondence

SYNOPSIS—Brief early history of alleged causes leading to a strike. Method used to force nonunion men into the Union. Recognition of the Union, the real object of forcing the strike upon the men.

The United Mine Workers of America claim to have paid, to this date, over $700,000 in relief money to the striking miners on Vancouver Island. If this amount were multiplied by ten it would, approximately, represent the loss inflicted upon the island by the payment of this amount of relief money. The United Mine Workers may boast of having expended this sum of $700,000, but their boasting only means that the island community has probably suffered a loss of seven millions.

Early History of the Strike

The strike on Vancouver Island began at the mines of the Canadian collieries, Ltd., located at Cumberland and Extension, September, 1912. Six months later it was extended to the mines of the Western Fuel Co., at Nanaimo, and those of the Pacific Coast Coal Co., at South Wellington. So far as the United Mine Workers are concerned the strike at these places still continues. During the whole of these sixteen months payrolls have either been stopped or very considerably diminished, while general trade and all the manifold businesses connected with the coal industry have been seriously affected. In Nanaimo alone, for the eight months and a half the strike has continued, the Western Fuel Co. would have paid out in wages only, approximately, $1,500,000.

The only cause of all this trouble, financial loss and the crippling of the island's coal trade at a time when it was enjoying an era of unprecedent activity, is the attempt of the United Mine Workers of America to force itself upon the operators on the island. Other causes for the strike have been alleged by the Union bosses, but they are mere pretexts used to conceal from the men the real object of the strike. Had it been understood by the miners, at the beginning, that they were striking for the recognition of the United Mine Workers of America, in the island, there never would have been a strike. For months and months paid emissaries of the organization had worked the various camps on the island without success. They picked up a few adherents in each of the camps but that was all and these were a negligible minority.

Methods Employed to Enlist Men

One of the reasons given by the leaders of the strike was that discrimination had been made against some of the union men and one, a man named Mottishaw, employed by the Canadian Collieries, Ltd., at Cumberland, it was claimed, had been discharged or refused further work when his place was finished, owing to his affiliations. The majority of mine employees, of course, knew nothing of the true particulars. The discharged man while an employee of the same company at Extension mine had served as a member of a gas committee and the officers of the United Mine Workers declared he had been discharged for reporting dangerous conditions in the Extension mine, as he was compelled to do by the Mine Regulation Act, while serving as a member of a gas committee. Reference was even made to the explosion at Extension, in 1909, before the present company took over the property.

As a result of these extraordinary efforts and pretexts, however, the paid officers of the Mine Workers failed to get a strike vote, at a mass meeting held Sunday morning, Sept. 15, 1912, and another meeting was called, for the same evening, which was attended by about one hundred and twenty-five men. To get over the general objection to a strike it was decided to take a holiday the following day, Monday. Pickets were sent out to stop all men from going to work. The management refused to meet a Mine Workers' committee, and the holiday became a strike. Like action was taken at Ladysmith, two days later and all the mines of the company were thus closed down.

This account of the origin of the strike is still being used by the Union bosses to enlist public sympathy. It was magnified into a charge of criminal discrimination by the company, and of criminal negligence by the provincial government in not enforcing the Coal Mines Regulation Act. These charges are absolutely without foundation. The discharged man Mottishaw was connected with only one gas committee and signed only one report in which there is no hint of dangerous conditions existing in the mine. All the reports, both of mine inspectors and gas committees, are on file in the Provincial Mine Department, and neither in June nor July, 1912, do they contain a hint of dangerous conditions. In fact, the June report, on account of which the man Mottishaw is alleged to have been discharged, states positively that the mine was in a "fair condition."

The "Gas Committee" Argument

These facts altogether dispose of the allegations that Mottishaw was discriminated against by the company for reporting the Extension mine unsafe, after an examination of the workings as a member of the gas committee. If other evidence were needed there is a statement of Frank Farrington, in a letter to the Hon. T. W. Crothers, Minister of Labor, Dec. 15, 1913, which states, "the mines were as safe as human hands could make them," and adds, "With experienced miners employed, the mines are still as safe as ever." The fact remains that the strike was undertaken solely to force men into the Union, and so enable the Mine Workers to demand recognition from the operators.

Relief money was paid to all men alike, whether or not they belonged to the Union; but the average man did not like the idea of drawing relief money without enrolling as a member of the Union; and, the more relief money a man drew, the greater he felt his obligation to the Union, and, consequently, the more reluctant he was to return to work. In this way, hundreds of men who had no sympathy with the strike, and strongly objected to the manner in which it was brought about, were yet bound to the Union.

The operation of this principle can be seen more plainly in what happened at Nanaimo and South Wellington. As soon as the Canadian Collieries Company realized the issue that had been forced upon it, it took steps to reopen the mines. In six months' time, the mines at Cumberland were almost back to their normal output, and over three hundred men were again working at Extension. The union bosses realized that they were facing defeat, and saw nothing for it but to get the men out at Nanaimo and South Wellington. They had tried already to do this by every artifice in their power; but, at these collieries, there were living agreements between the men and the operators and there was no complaint, either as to wages or working conditions. They could not break into the men, who even remained indifferent to the taunt that they were indirectly "scabbing" against their fellow-workers at Cumberland and Extension. As a matter of fact, the Union organizers had been able to make no headway at Nanaimo, and out of a camp of 1500 men there were not 200 members of the Mine Workers. A big coup was necessary.

The Call for a Strike Issued

The first day of May was to be observed as a labor holiday, in and around Nanaimo. Seeing that there had been a strike at Ladysmith for six months, it was arranged to hold a big demonstration there on the holiday. On the 30th of April, Frank Farrington, the chief officer of the Mine Workers, on the Pacific Coast, issued a strike call from Seattle. It was addressed to R. Foster, the local president of the U. M. W. of A., and instructed him to "call a strike of all the men employed in and around the mines at Nanaimo, South Wellington and Jingle Pot; the strike to begin May 1, and to continue until a joint working agreement between the United Mine Workers of District 28, and the mine owners on Vancouver Island was secured." It will be noted that the object of the strike is here definitely stated as recognition of the Mine Workers, and it should be borne in mind that at that time there were not 15 per cent. of the miners of Nanaimo members of the organization.

The first feeling among the miners, as well as the general public, was to regard the strike decree as a joke. This feeling soon changed to anger and consternation. The union organizers made the most of their opportunity with the men attending the demonstration at Ladysmith. They had also arranged for a mass meeting, at Nanaimo the same night, at which meeting all opposition was ruthlessly silenced. Those of the men who advocated living up to their agreements with the operators were shouted down, while others who asked for a ballot were told there was no need for one. Ervine, one of the leading organizers, declared that the man who went to work would be a "scab." In view of these circumstances, the men opposed to the strike called a meeting for the next night, but it was broken up by rowdyism. They then decided to make one more effort to secure a ballot; but, while they went through with their proposal, it was rendered nugatory by the strike-makers. President Foster got out a dodger, which was circulated and posted all over town, in which it was declared that "a strike had been called and ballot or no ballot, any man who went to work would be branded as a "scab." In the face of this intimidation, and the presence of a large and threatening crowd around the ballot station, less than five hundred votes were cast on the question of striking. Of this number, less than forty voted to strike. It was by these methods that the strike was made general on the island; and, as at Cumberland, the men opposed to the strike felt obliged to join the union.

Not a Free Ballot

It will be noticed that, in neither case was a free ballot taken. It must also be recorded that during all the time the strike has lasted, a period of 16 months, such a ballot has never been taken. It will again be observed that, on the basis of membership, the officers of the Mine Workers had neither right nor justification in calling a strike. It must also be concluded that even after the majority of the men joined the organization, its officers have always been afraid to refer the issue to a ballot. The Western Fuel Co. has made three separate overtures for a settlement. On one occasion it offered to meet a committee composed of seven of its employees, to be elected at a mass meeting, to discuss and arrange an agreement. This agreement would again be referred to the men for ratification by secret ballot. The committee thus elected, if agreeable to the men, could act as a standing committee, for a period of time to be agreed upon, for the purpose of taking up any grievances that might arise in the daily operation of the mine; and the company would meet the committee, at least once a month or oftener if required, and also pay the wages of the men while attending these meetings. The offer was turned down without reference to the men; and thus it happens that, while in the beginning the miners were ordered out on strike without a vote, so in the end they are committed to a game of "freeze-out" without a vote.

It is also true that the men who have thus been jockeyed out of their employment enjoyed unusually favorable conditions of work. It is important that the miners in the States who have contributed over seven hundred thousand dollars to the support of the miners on the Island of Vancouver should know and realize this fact. The province has one of the most complete and uptodate Mines Regulation Acts in the world.

All the mines are equipped with a Draeger Rescue station, and all the mine workings must be examined by provincial mine inspectors at least once a month. There must also be a monthly inspection by a gas committee appointed by and representing the men. The working day is fixed by statute, as eight hours from bank to bank. As for wages, the average wage for the year preceding the strike, in the mines of the Western Fuel Co., was $4.86 a day for contract diggers and $3.20 a day for company miners. For April, the last month the mine worked before the strike, the average daily wage of diggers was $5.11 and of loaders, also on contract, $4.34.

Taking conditions right through, it is extremely doubtful if there is a colliery on the American continent that will compare with the Nanaimo mines of the Western Fuel Co. and the situation today is that every mine on the island is operating. Over five hundred men have returned to work in Nanaimo, and as fast as places can be made ready, men are offering themselves. The strike is hopelessly beaten, but at an immense cost to the coal operators, miners, and the general community of the Island, as well as to the miners of the States who have been mulcted in behalf of men enjoying better conditions then themselves.

How an Explosion Is Modified by Obstructions

SYNOPSIS—An explosion is created in a gallery which is obstructed, more rapidly than in one which is clear but we must not assume that the presence of these obstructions makes any difference to the ultimate force of an explosion. In a short gallery the effect of an inflammation of coal dust does not have time to reach its maximum unless constrictions are provided to create favoring conditions.

Many experiments, of which that described (No. 119) in a previous article is an example, were made with the gallery perfectly clear, so that the inflammation was free to travel from one end to the other without encountering any obstruction which might cause irregularity in its development.

Previous to the commencement of a systematic study of the manner of development of the explosions, however, the gallery had been used for demonstrating the fact that coal dust was capable of forming an explosive mixture with air. In these demonstrations, the inside of the gallery was furnished with props and timber set to represent the manner in which the roof of the roads in coal mines is supported.

The timbering consisted of pairs of wooden props, 6 in. in diameter, fixed on either side of the gallery with a tightly-wedged bar at the top holding them in position. These pairs of props with bars were fixed every 9 ft. throughout the gallery; the force of the explosion usually dislodged all of them, projecting some of them 300 or 400 ft. out of the open end of the tube and giving an effective proof of the power of an explosion of coal dust and air to do damage. See "Record" of the Mining Association, p. 91, and following pages.

Obstructions Increase Side Pressures

The pressures recorded during these demonstrations sometimes amounted to as much as 50 lb. per square inch for a distance of travel of the explosion of only 225 ft. In contrast to this, it has already been shown that when the gallery was clear a pressure of only 16 lb. per square inch was developed after a distance of travel of 450 ft.

Several series of experiments were therefore made with a view to determining the influence of constrictions in the gallery on the propagating of an inflammation. These experiments bring out very clearly the salient difference between "inflammation" and "explosive combustion," and show that the change from the one type of propagation to the other is susceptible of control.

Inasmuch as a large number of constrictions, such as were represented by the props and bars in the demonstrations, so complicated the phenomena as to render the pressure-curves obtained hardly intelligible, the effect was tried of introducing one constriction at a time.

Note—Third part of the fourth report of the British Explosions in Mines Committee. The two previous parts are "Concussion as a Cause of Explosions," Jan. 3, 1914, Vol. 5, pp. 19-21, and "The Transition from Inflammation to Explosion of Coal Dust," Jan. 31, 1914, Vol. 5, pp. 207-210.

Constriction Only a 6-in. Ring

The constriction was obtained by bolting on to the inside of the gallery an angle-iron ring having a 6-in. flange which reduced the diameter of the gallery at the point where the ring was fixed from 7 ft. 6 in. to 6 ft. 6 in., the amount of surface exposed at right angles to the direction of movement of the explosion being 11 square feet.

In the series of experiments to be described, the point of ignition was 400 ft. from the open end. The method of performing the experiments was in each case exactly the same as in experiment No. 119, of which details have been given.

Explosion Produced 2 lb. Pressure in a Smooth-Sided Gallery

The first experiment of the series (No. 123, June 22, 1910) was made with the gallery clear of all constrictions. A slowly-moving inflammation was all that was produced. The pressure-curve traced by the manometer most distant from the point of ignition, 350 ft. (No. 6, Fig. 1), showed a maximum pressure of only 2 lb. per square inch, and that pressure was attained but slowly. Moreover, the curve shows no sign of any sudden rise of pressure such as accompanies "explosive combustion."

The effect of introducing a single constriction at a point 200 ft. from the point of ignition (experiment No. 142, Aug. 26, 1910), was to raise the maximum pressure produced to 105 lb. per square inch for the same distance of travel. This maximum pressure was attained about one second after ignition, as against 1½ sec. required when no constriction was present. The pressure curves, which are described later, indicated the beginning of "explosive combustion" at a point about 350 ft. from the point of ignition.

Pressure Rises Faster, the Rougher the Gallery Lining

A single, constriction, therefore, shortens in a remarkable degree the distance that has to be traveled before "explosive combustion" begins.

A second similar constriction was now introduced at a point 250 ft. distant from the point of ignition, (experiment No. 144, Aug. 30, 1910). The maximum pressure, which was attained about three-quarters of a second after ignition, now reached 21 lb. per square inch, and the curves traced by the manometers both at 350 and 300 ft. from the point of ignition, showed the abrupt increase in pressure that we regard as indicative of explosive combustion.

When a third constriction was made, at a point 300 ft. from the point of ignition, (experiment No. 139, Aug. 23, 1910), the maximum pressure produced was 55 lb. per square inch, attained about two-thirds of a second after ignition

In order to bring out the important features of these experiments, it is not necessary to reproduce all, or the whole of any one, of the pressure-curves traced during each experiment. We have already shown that for a considerable period after the time of ignition, the pressure-

curve traced, is merely that due to the igniting-cannon and is of no particular interest from the point of view of the development of coal-dust explosions.

To avoid confusing diagrams, therefore, those portions of the curves that were due to the igniter pressure are omitted in Fig. 1. Further, although in each experiment records were obtained of six manometers (fixed 100, 150, 200, 250, 300 and 350 ft., respectively, from the point of ignition), the curves of chief interest are, as can readily be understood, those traced at the points most distant from the point of ignition, after explosive combustion had been attained. Therefore, these curves only, are reproduced.

Explanation of Diagrams

Examination of these curves show the effect of constrictions very clearly. The curve at the top, Fig. 1, shows the pressure recorded at the manometer most distant from the point of ignition—350 ft.—when the gallery was clear of all obstructions. It is obvious that the result was merely a slow inflammation.

The diagram below this curve reproduces two curves traced during experiment No. 142, in which one angle-iron constriction was fixed at a point 200 ft. distant from the point of ignition. No. 5 curve is that obtained at a point 300 ft. from the point of ignition and No. 6 that at 350 ft. distance; this latter curve, therefore, corresponds with No. 6 curve in experiment No. 123, when the gallery was clear. It will be seen that there are distinct signs in No. 6 curve of experiment No. 142, of the sudden rise of pressure, indicative of the beginning of "explosive combustion"; this occurs after an interval of 97 hundredths of a second from the time of ignition.

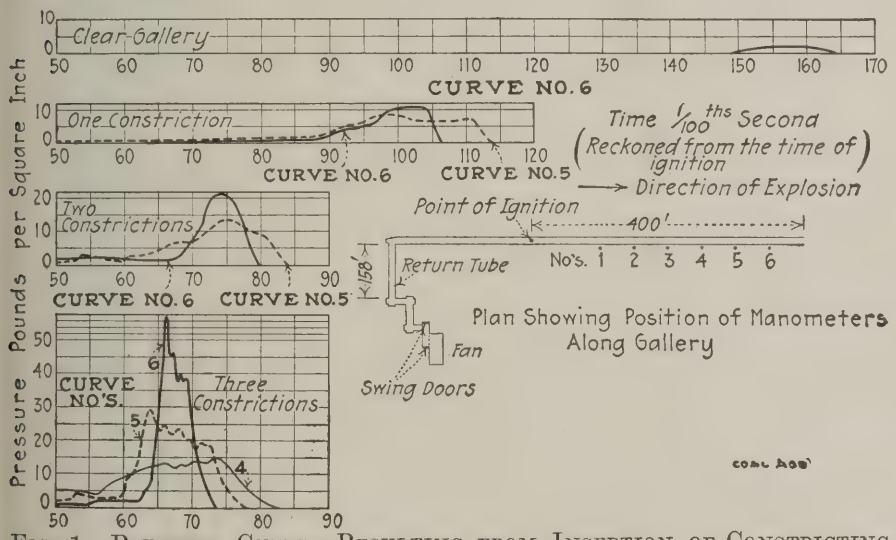


Fig. 1. Pressure Curves Resulting from Insertion of Constricting Obstructions in Exploson Gallery as Measured by Manometers 4, 5 and 6

The next two curves, No. 5 and 6, of experiment No. 144, show the result of introducing a second constriction at a point 50 ft. distant from the first. In this case, there are indications of the beginning of "explosive combustion" in curve No. 5, at a distance of only 300 ft. from the point of ignition.

Lastly, the two curves, No. 5 and 6, of experiment No. 139, (in which three constrictions had been introduced) both show the sudden rise of pressure, due to "explosive combustion" which has apparently begun to be developed (as shown by curve No. 4) within 250 ft. of distance from the point of ignition.

Summarising: The influence of constrictions on the development of the explosion as shown by this series of experiments, was as follows:

Number of Constrictions	Maximum Pressure Developed, Lb. per Sq.In.	Interval of time Between Ignition and Attainment of Maximum Pressure. Hundredths of a Second
None	2.0	155
One, 200 feet from the point of ignition	10.5	103
Two, 200 and 250 feet from the point of ignition	21.5	74
Three, 200, 250, and 300 feet from the point of ignition	57.0	66

The most striking comparison is perhaps obtained from experiment No. 119, already described, and No. 137

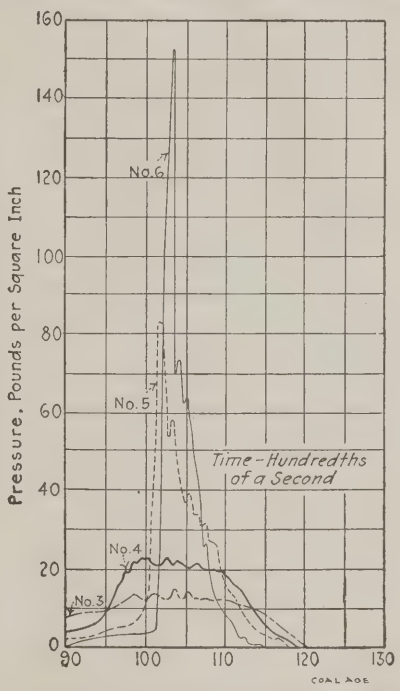

Fig. 2. The High Pressures in This Figure, Showing Experiment No. 137, Exhibit Effect of Constrictions in Path of Explosion

July 28, 1910). In the former, it will be remembered, the point of ignition was 500 ft. from the open end of the gallery, and the gallery contained no constrictions. In the latter, three constrictions were introduced at points 300, 350 and 400 ft. from the point of ignition. Except for the presence of these constrictions, the experimental conditions in experiment No. 137, were the same as in No. 119.

The pressures recorded by the manometers along the gallery were as follows:

Distance of Manometer from Point of Ignition, Ft.	Experiment No. 119 (Clear Gallery) Pressure Lb. per Sq.In.	Experiment No. 137 (Three Constrictions). Pressure Lb. per Sq.In.
300	4.5	23.0
400	6.5	83.0
450	16.0	152.0

Assumption That Constrictions Increase Ultimate Violence Is Not Warranted

The essential parts of the four curves recorded by the manometers most distant from the point of ignition, in experiment No. 137, are reproduced in Fig. 2. If these

curves are compared with the corresponding curves of experiment No. 119, which are reproduced in the previous article, the remarkable effect produced by offering a slight obstruction to the passage of the explosion at, but three points along its path, 50 ft. apart, will be appreciated. We do not propose at this stage to discuss the theory of constrictions in augmenting the intensity of explosions of gas and coal dusts; but we would point out that the effect of such constrictions in the gallery and, presumably, of obstructions in the roadway of a mine is not necessarily to increase the *ultimate* violence of which a coal-dust explosion is capable, but to enable it to obtain violent proportions at a much earlier period than in a smooth gallery.

Experiments which are now being carried out at Eskmeals illustrate and confirm many of the experimental conclusions above set forth. We hope shortly to give an account of them.

The Price War in the Markets of the Pacific

By W. A. MacCorkle*

SYNOPSIS—The Panama Canal does not furnish the shortest route from Europe to Asia and Australia but may supply the most economical, in view of the relative cheapness of good coal along the way. Coal is carried for less than cost by ship owners who are seeking ballast for their empty bottoms but this practice is declining. The author expects the coal of West Virginia to dominate at least at the Panama Canal and along the nearer coast of the Pacific.

The Suez and Panama Canal routes, respectively, control the great international trade lines of the world. Which of the rival routes will receive the bulk of the traffic will not be decided solely by the relative distances of travel, which using one or the other will entail. After a somewhat careful investigation of these great trade routes, it seems that the shipowner will use one route or the other, actuated not only by mere distance but also by the price and quality of the fuel he can purchase along the line.

Panama, the Greatest Coal-Distributing Point in the World

If the route through the Panama Canal becomes that most generally used by the ocean-going ships of the world, the isthmus will in itself become the greatest coal-distributing point upon which the sun shines and this fact will make the fuel of West Virginia one of the preponderating influences in the world of trade.

The great markets of the North Atlantic, from which come the life of commerce, are already taken and firmly held. Today, the great market for competition is the mighty Pacific and upon the shores encircling its bosom are the unoccupied markets for which the world will join in deadly competition. Its shores are the longest, its seas are the quietest, its populations are the most teeming and many of the essentials of life are the products of the lands encircling this great ocean.

Gold, silver, precious stones, splendid woods, dyes, rubber, silks and all things necessary to life are here produced. Nations, yellow, brown and white, filled with the desires of new commerce, fired with new hope by the touch of the West, thrilled with new ideas of government and religion, are all mingled in one tremendous combat for the mightiest markets vouchsafed to man since the stars sang together. If the nations of the world approach this empire of commerce through our canal, it means millions of tons of production for West Virginia, and a gold stream pouring in our beautiful valleys and amidst our people, which will be as unending as time.

The eternity of this possession is appreciated when we understand that of the 150 billions of West Virginia workable coal, only two billions have been mined, leaving within our state 148 billions yet untouched. It is generally understood that the canal shortens the distance between Europe and the East, and places the advantage of the distance with us. But let us look at the plain facts.

Panama Canal Route Not as Short as the Suez between Europe and Eastern Asia

All of Asia and Australia and the East generally are nearer Europe by the Suez Canal than by the Panama route. This is not popularly understood. The distance from Liverpool to Adelaide by the Suez route is 11,142 miles. Via the Panama route, the journey is 13,478 miles, the Suez Canal being the shorter by 2336 miles. To Manila from Liverpool via the Suez Canal, the distance is 9701 miles, by the Panama route 14,122 miles. Thus the Suez route is 4421 miles shorter than the other. To Hong Kong from Liverpool by the Suez Canal is 9785 miles, by the Panama Canal 13,957 miles. Thus the Suez Canal has an advantage of 4172 miles. To Yokohama from Liverpool by the Suez Canal is 11,678 miles, and by the Panama Canal 12,372 miles. Here, also, the Suez Canal is the shorter, this time by 694 miles. I give these distances at length to show that it will be cheap fuel and not distance which will largely control the great bunker trade of the world, if Europe uses the Panama rather than the Suez Canal.

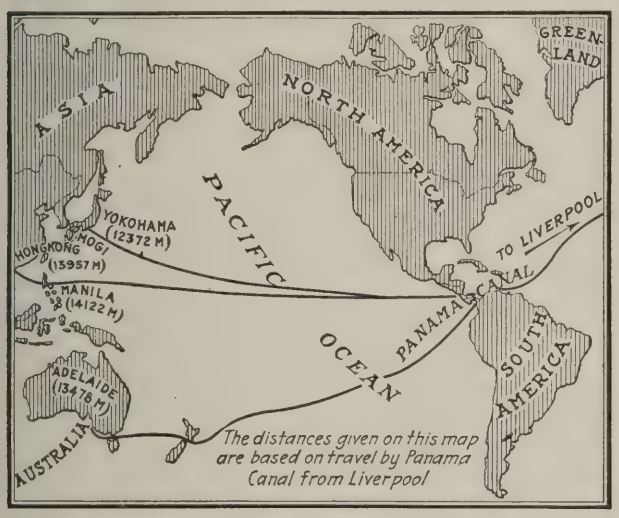
The United States Coal to Dominate Pacific

The use of the Panama Canal will give New York 4138 miles advantage over Liverpool on the journey to Wellington, New Zealand, and the distances will be about equalized, relatively speaking, on the journey from New York and Liverpool to the countries I have mentioned.

The canal should allow this country largely to dominate by distance the coast of South and Central America.

One enormous advantage today, possessed by the Suez Canal, is the fact that coaling stations are located along

*Ex-governor of West Virginia, Charleston, W. Va.



Note—Abstract of first part of an address entitled "The Relation of West Virginia Coals to the Panama Canal" read before the West Virginia Coal Mining Institute, Charleston, W. Va., Dec. 8, 1913. The author acknowledges the assistance of Neil Robinson, president of the association in furnishing material for the address.

the great English trade routes, so as to give the greatest accommodation to the trade of the world. If this country proposes to take any part of the steaming demand of the world from the English nation, it must provide ample coaling stations for international commerce.

It is the province of the government of the United States to provide at the Panama Canal a great coaling station where the ships of the world may obtain their fuel at a cost affording a fair profit to the producer and to the shipowner. This is now being done, and at both ends of the canal our government is constructing the most modern coaling stations ever used in the trade.

Need for an American Marine

If these markets become as important in American commerce as they should be, America must control the ships necessary for her trade. Let me illustrate my argument by showing that length of voyage and cheapness of fuel do not always settle the cost of transportation. The marvelous ability of the Englishman to ship his coal to every part of the world and sail his ship in every sea, despite the competition of the nations, is well exemplified

Maps Illustrating the Relative Distances from Europe to Pacific Ports

on the coast of South America. At Valparaiso, Iquique, Antofagasta and other points on the western coast of South America, the coal is largely Welsh and Australian, because of the low freight rates on vessels bound for Chili to secure nitrates. On the eastern coast of South America the same condition exists; British ships control the markets and are able to take coal cheaply to different coasts, as they can obtain the return traffic.

In other words, American coals cannot obtain the markets to which they are entitled, unless American ships are more plentiful upon the seas and American trade is more diversified under new laws and new conditions. Only then may we send our products into every country and among every people.

Cost of Coal at Panama, $5.09

To test the accuracy of the statement as to the possibility of coal being sufficiently cheap at the Panama Canal to affect the route taken by the world's trade, let us consider the facts as they stand today.

The prices now paid by the Government at Panama have been fixed for two and one-half years, and the coal which is used there comes from West Virginia, which was determined to be better for all purposes at the Isthmus than any other coal. This conclusion was reached after the Government had considered all the coals in the market. It is paying $2.70 at Norfolk for this coal and $1.29 for its transportation to the Isthmus. The contract provides that if the commercial price of coal declines, the contract price is to be reduced to $2.65 per ton. If this price prevails the cost of coal at Colon will be $4.09½. With all the lighterage, depreciation and overhead charges added, West Virginia coal will cost $5.09½ at Panama, or if the price at Norfolk should be reduced during the contract it will be $5.04½. It will also be possible for coal to be sold by the canal authorities at $5.54½ on the Pacific side of the Canal.

Welsh Coal at Port Said Costs $6.33 per Ton

In 1912, the contract price of Welsh coal at Port Said was $6.33 per ton, and it seems beyond question that coal can be profitably sold by our government at Christobal for $1.20 to $1.25 less than the prices charged at Port Said. The cost of Welsh coal is necessarily increasing year by year.

In a careful calculation made by the Government, a ship of 4640 tons, gross register, operated at a speed of ten and a quarter knots on a round trip made in 1911, between New York and Manila, by way of the Suez Canal, consumed 4475 tons of coal, at a cost of $20,868.75.

Careful calculation made by this Government upon the prevailing prices for the same ship, leaving New York, coaling at Newport News, Colon, San Francisco and the Japanese ports and back again, coaling at Mogi, San Francisco and Colon, would only use $18,222.50 worth of coal for the whole trip, the cost of fuel being in favor of Panama by $2,646.25. Upon the prevailing prices for 1912, the same ship making the same voyage by the Panama route would expend for coal $18,567, but by the Suez route it would be $22,608.75, or a difference in favor of the Panama route of $4,041.75.

In other words, it is fairly established in the trade of the world that prices for coal will be less by the Panama Canal than by the Suez route. If this is so it seems as if the Panama route while longer often times than the Suez route, will be largely used for the reason that the price of coal will lessen the cost of the voyage.

Discussion on Mixed Lights in Mining

SYNOPSIS—The meaning of the expression "mixed lights" explained. An illustration showing the danger of such practice in respect to a possible fall of roof in the gaseous section of the mine. Danger due to careless neglect of rules and regulations—an incident. Igniting the gas for sport, a fool trick. Practice in the Pennsylvania anthracite mines. Illinois conditions and practice. Rule adopted in the T. C. I. mines in Alabama. Ordered the use of safety lamps in mine drawing pillars, in Illinois. Practice in New Mexico mines. Experience in gassy mines in Pennsylvania.

President Adams, in opening the session, announced that he believed Mr. Beard was greatly interested in the question of the use of mixed lights and he would ask him to kindly start the discussion of the evening.

Mr. Beard (*New York*)—We understand by the expression "mixed lights" in gaseous mines the use of both open lights and safety lamps, in any portion of a mine where certain sections of that same mine are required to be operated by safety lamps only. I believe there are many gentlemen here who are better able to discuss this question than I am, for the reason that they have had much practical experience along these lines. I will give you a few illustrations that certainly convince me that the use of mixed lights is an unsafe practice.

Danger from Heavy Roof Falls

Suppose, for example, we are operating a large mine one section of which is gaseous and the rest of the mine is known to be free from gas. We install a lighting station at the entrance to the gaseous section, assuming that that makes a satisfactory and safe arrangement. There is a man put in charge of the lamp station and no one is permitted to enter that section of the mine without a safety lamp. The other section is worked on open lamps. Under the general mining practice, that has been and is still considered safe. Suppose now a heavy fall of roof occurs in the gaseous section, what is to prevent the gas from being driven out in large quantities from some of the abandoned portions in that section into the places where open lights are used and a serious explosion taking place? That is one instance that, to my mind, condemns the use of open lamps and safety lamps in the same mine.

Careless Neglect of Rules and Regulations

Again, when open lights are allowed in many gaseous mines, safety lamps are only used at the working face. I have known a number of cases where we were required to leave our torches and take a safety lamp when entering a chamber or approaching the working face. Under those conditions you know that many miners will take their open lights up to the face unless they are closely watched; and as is frequently the case, in these workings, the open lights will be used when the boss is not around. If they are caught the boss would, of course, tell them not to do that again and threaten them; but he probably would not discharge a man, because good miners are hard to get. A foreman, if asked, will give the excuse for not calling down any violation, that he cannot afford to discharge a good man for a little matter like that.

I remember a few years ago I was in a gaseous section of the Marvin shaft, at Scranton, Penn.; it was in the evening. The mine foreman, two firebosses and myself were going in, and about 100 yd. from the head of the entry there was a board marked plainly "Gas," and laid across the track so that we had to step over it. Now, in that mine, no open lights were allowed at the face. We had gone, however, but a short distance further when we could see the glimmer of lamps that were evidently open lamps or torches, up the entry. The mine foreman said to us, "Wait a bit," and went quickly ahead to where the men were and made them extinguish their lights at once. We followed directly and found the foreman giving the men a calling down for taking their open lights beyond the board. Later, I said to the foreman, "Is that all you are going to do to those men?" His reply was "We cannot afford to discharge good men, at this time; good men are hard to get. I know it is a violation of the law, but we cannot help that; we are not going to let a good man go for a little matter of that kind." Proceeding a short distance further, at the inby corner of the last breakthrough, holding a lamp just inside of the corner, we could get a lamp full of flame. We could not get into the head of the entry on account of its being full of gas and therefore unsafe to enter. It was only good luck that no accident occurred at that time. A small fall of roof in the head of the entry would have driven the gas out on those men and the explosion that would be sure to follow would have blown them to pieces and endangered the life of every man in the pit.

But I would rather listen to you. These are only suggestions that come to me; there are many others; but I know that you can give many incidents and arguments for and against the use of mixed lights. I can only say that the excuse for the use of open lamps in mines generating gas is, as we all know, that the miner can see to mine coal better, and for that reason they do not care to use a safety lamp. My opinion is that we ought never to use a safety lamp where it can be avoided, that is to say, where the mine can be made safe to work with open lamps; but this must be done by having ample ventilation.

Lighting the Gas a Fool Trick

The practice of using open lights beneath a layer of gas at the roof, where we are cautioned not to raise the lamps and where the boys will light the gas, just to see how it affects you or some greenhorn in the mine, such fool practice is to be condemned by every true miner. I was in one of the mines, I forget which one, at Scranton, some years ago, and there was a layer of gas at the roof of every chamber in one portion of the mine, at least. The gas was being given off at the coal face to that extent that it just maintained a thin layer continuously, close to the roof, at the face, and we were cautioned to keep our lamps down and did so. I had with me, at that time, a

Note—From the published Proceedings of the sixth annual meeting of the Mine Inspector's Institute, U. S. A., held at Birmingham, Ala., June 10-13, 1913.

commercial man who had never been in a coal mine before. He came there to get a little idea of what a coal mine was like. On retiring from the chamber we had not gone more than probably 75 or 100 ft. from the face when the boys for a joke, laid down and raised their lamp into the gas and lit it. The flame rolled down toward us and came within 20 ft. of us. I ducked and pulled my friend down. When he saw the flame had fallen back again and we were out of danger, he said, "What did you duck for?" But the mine foreman answered him very promptly, "A good miner always knows when to duck," which is very true. It must be remembered that an explosion does not develop immediately on the ignition of the gas, which will burn a certain distance and then recede and again advance and fall back a second or third time; but that action of the gas, in many cases, develops energy enough presently to burst into an explosion that extends more or less throughout the mine.

MR. MCALLISTER (*Illinois*)—How many years ago was that?

MR. BEARD—That was in 1905.

MR. MCALLISTER—I don't think you will find those conditions existing today in the mines.

MR. BEARD—Around Scranton? That is the condition today, in some of the mines near Scranton.

MR. RODERICK (*Pennsylvania*)—Was that in the face of the workings?

MR. BEARD—It was right in the face of one of the chambers.

MR. RODERICK—Some of the inside chambers?

MR. BEARD—Yes.

ANTHRACITE (PENN.) PRACTICE

MR. RODERICK—I will state, for the benefit of Mr. McAllister, that that is a frequent occurrence in the anthracite region. Of course, the veins are higher than in most of the bituminous workings; and, in the rooms of a gaseous mine, even a wing brattice would not keep it back. Then they use nothing but batteries to fire the shots. The mines of the anthracite region that are gaseous give off an enormous volume of gas. You can catch it from the sides, coming from the roof, bubbling up in the ditches. It takes a strong current of air, and unless the air is kept up to the face all the time, there is liable to be a thin layer near the roof. Now, as a rule, the men work with their lights on the bottom, or else use safety lamps altogether. But conditions are improving and I don't think you will find many places today in that condition.

MR. MCALLISTER—It is a fact, is it not, that the miners never see the roof in those mines?

MR. RODERICK—The Mammoth vein in the Hazelwood district and in the Schuylkill district runs from 30 to 35 ft. in thickness, and the miner with his small light hardly ever sees the top in those thick seams. On the pitch, of course, they get back to the top, by cutting the coal back, and leaving it under their feet.

PRACTICE UNDER ILLINOIS CONDITIONS

MR. BACK (*Illinois*)—In my district, in Illinois, there are some gaseous mines; but the conditions are not such as to require the use of safety lamps. In my opinion, if there were places or sections in a mine that should be worked with safeties, I would put the whole mine on safety lamps. I think it is a wrong idea to use open lights in one section when other sections require safety lamps. I believe the use of mixed lights is dangerous, because it is always possible for some one of the miners to slip through and carry an open light into the gas; and there is the danger.

MR. ADAMS—You are supposed to put a policeman at the entrance of that section and not allow a man to enter it with an open lamp.

MR. RODERICK—I don't consider there is much danger in a mine that is giving off gas only; but if there is dust it might increase the danger. You can generally arrange a mine so that a large portion can be worked with naked lamps while the live workings should be put on safety lamps. It may entail the extra expense of keeping somebody there to see that no naked lamps are taken into the gassy section.

As an illustration, let me say I had charge of a mine at one time and the conditions were like what Mr. McAllister has described. The seam had a heavy pitch; the coal was very free and would run of its own accord after being opened out to the proper width. It would come to the battery as fast as you could load it out; but, at times, a place would stop running, and that would cause an accumulation of gas in the chute, above the battery, for the coal was making much gas. Although a good current of air was passing on the level, yet for fear of a fall in some of the breasts bringing the gas down on the gangway. I put that section on safety lamps and put a man there in charge. If a driver came in carrying an open lamp, it was taken away from him and he was given a safety lamp. That was the only section that they had to put on safety lamps, as I thought it was not right or just that the whole mine should be put on safeties because that one lift was dangerous, and I did not do it.

MR. FLYNN (*Alabama*)—If I understand this subject, it is not a question of what would be safe at one mine or two or three mines; but what would be a safe rule for all mines. Of course, there are exceptions to all rules and there are varying conditions in coal mines; but this question should be discussed from a general standpoint and a general practice. The question should be discussed in a manner to bring out the points as to whether it is advisable to lay down a principle that both open and safety lamps could be used in the same mine, at one time. I do not mean in any one particular mine in Pennsylvania or in Alabama, but in all mines; because in discussing this question, I suppose it is with a view of discovering whether it is advisable to have laws enacted prohibiting the use of mixed lights in coal mines.

I, for one, would never consent to the use of open lights and safety lamps in the same mine. While I have seen conditions where it would be considered safe, I have seen other conditions where it would be dangerous. But, if it is safe to work them in *ten* mines and dangerous to use them in *one* mine, then I say the danger in that one outweighs the safety in the ten, and it would not be a good practice to pursue.

THE T. C. I. MINES IN ALABAMA

I am going to give a little of my experience with the use of mixed lights in coal mines. When I accepted the position with the Tennessee Coal, Iron & Railroad Co., I found they were using safety lamps in the advance work-

ing places that were generating gas. I found on investigation that there was no law to stop it. I talked against it and advised against it; but the opinions of other mining men were opposed to mine. However, having accepted the position with the company, I had some authority and immediately recommended that no safety lamps be used in any of our mines. Most of our mines are making a little gas. Formerly, the rooms were turned and worked before the entry breakthrough was cut; and if those places were generating a little gas, it was the custom to give them a safety lamp until the breakthough was made. We were continually having men burned under that system; some seriously, others not as seriously, but some fatally.

The question was asked: What are you going to do if you stop working safety lamps in those places? I replied: We are going to put the air in there; we will carry a line of canvas brattice from the crosscut to the face and conduct the air right to the face. In every room there will be a line of brattice from the heading to carry the air to the face. After some argument on the question the general superintendent agreed with me that that would be the best policy and immediately issued orders that safety lamps should not be used. If it was found that a place was not safe, work would be stopped until it was made safe.

No man in the mines of the T. C. I. Co. is now allowed to have safety lamps, except the firebosses and the bratticemen. The firebosses use safety lamps exclusively. We do not even allow a fireboss to wear a cap with a tin. The reason we made that rule was because one of our firebosses was burned and investigation showed that he had a cap with a light on it unbeknown to anyone. This man would go in the mine about 3 o'clock. No one would see him going in and when coming out he always hid his cap with the open lamp and no one knew he had it. He would come out, eat his breakfast and then finish his shift with a safety lamp. His open light, however, set fire to some gas and he was burned and died five days later. A man holding a lamp in his hand is not so apt to forget about it as one with a lamp on his head.

Results of Excluding Safety Lamps

Since we have adopted this system, I am glad to say that all last year (1912) we only had two men burned in all the gaseous mines we operate. This was caused by two miners, who came out of their room leaving the canvas torn down; and while they waited for another car there was a little accumulation of gas, which they ignited with their lamps, on returning to the face. All of our mines are operated now with open lights. We require our firebosses to examine every working place in the mines, each day before the men enter for work. He must mark the day of the month near the face of the coal. We do that to insure that he has gone up to the face; then he marks the date on the timbers as a reference mark. After he has done that he comes out and meets the men before they enter the mine and every man has got to pass that fireboss and ask as to the condition of his place. If the fireboss reports gas in a certain working place, the man is stopped and not allowed to proceed until the day fireboss and bratticeman have gone there and made the place safe. In my opinion, it is bad practice to allow open lights and safeties in the same mine.

Mr. Williams (*Pennsylvania*)—I want to ask Mr. Flynn a question or two. In the first place, would you penalize the nine mines because the tenth, in your opinion, was dangerous? And, another question: Do you have gob gas in Alabama?

Mr. Flynn—In answer to the first question I will say yes, I would penalize the nine, if by so doing I can render the tenth mine safe for operation, and for the protection of the man in that mine. This is as it should be, and who would not do the same thing? In answer to the second question, I will say, we have some gob gas in Alabama; but not, perhaps, to the extent you have it in Pennsylvania. We have gas accumulate over the falls, where the ventilating current cannot reach. But in Alabama, especially in the T. C. I. Co.'s plants, with which I am most familiar, the old works are examined every two weeks by the firebosses. They must go into every abandoned and worked-out place and examine them for gas and if they find any, the mine foreman must immediately start to remove that gas.

Mr. Williams—Does the T. C. I. allow men to work on the return side of the falls and only examine worked-out places once every two weeks?

Mr. Flynn—As a general proposition the air travels in a separate split in one or two rooms, and then joins the current. Where this is the case no gas has ever been detected in the old workings, or over the falls, or anywhere else.

The Fireboss and the Alabama Law

Mr. McAllister—Does the law in Alabama require the date of the month to be put on the face of the workings?

Mr. Flynn—No, it is not in the law. The law provides that if the fireboss finds gas he must put a danger board across the entrance to those places. The law also requires that the fireboss must notify each man as to the condition of his place and each man must pass the fireboss station and see the fireboss before he is allowed to enter the mine for work.

Mr. Roderick—Does not the law require them to put the date of the month on the face of the working places?

Mr. Flynn—It does not.

Mr. Roderick—Why does he put it there?

Mr. Flynn—It is a rule laid down by the inspector that the fireboss must put the date on the face of each working place, but it is not the law.

Mr. Roderick—Then you require the fireboss to examine all working places whether they give off any gas or not?

Mr. Flynn—We do.

Mr. Kelso (*Alabama*)—May I ask, why you are opposed to safety lamps in any one entry?

Mr. Flynn—Because it is a dangerous practice, for the reason that you give a man a safety lamp to work with and the drivers, watermen, tracklayers and other employees are constantly passing on the gangway and may enter the place with an open lamp.

Mr. Kelso—I agree with Mr. Flynn on the wing-brattice proposition but not in respect to working with safety lamps. I believe he stated he had two men burned on account of their breaking down the wing-brattice. I think the men in the entry should also have safety lamps and if for any cause they have to leave their place for any length of time, they should examine it again before returning to work.

Mr. Flynn—It was the custom in the past, as Mr. Kelso well knows, that the fireboss on finding gas in a working place, in the morning, would take a piece of canvas and brush it out. Now, in a number of instances, the miner himself does not understand the operation of the safety lamp; does not know how to use it; or could not tell when the place was clear of gas. He would come in and put his lamp down and start to brushing out the gas, which would fire on his lamp. I can recall three or four instances that occurred that way when that was the common custom.

Mr. Roderick—When a place is generating gas, what is the standard shot?

Mr. Flynn—The maximum charge is two sticks of dynamite.

Mr. Roderick—Then I will say that is a very dangerous habit not to require safety lamps to be used in entry work. Take a mine generating any quantity of explosive gas, and suppose you strike a strong blower with a shot that a man might fire. Suppose he goes back to a place of safety and waits a certain length of time and the brattice was blown down by the shot so that the air does not reach the face of the entry. The man returns with open lamp on his head and lights the gas in the face of the gangway. I see no harm in using safety lamps in an entry or breast, after firing a shot and believe this should be done if the heading is giving off much gas.

Mr. Flynn—When a man shoots under these conditions, we have a day fireboss, and the man is not allowed to go back until the fireboss has been there and thoroughly examined the place for gas.

Ordered Mine Put on Safety Lamps

Mr. Dunlop (*Illinois*)—We in Illinois are not troubled with mines that generate explosive gas to any extent, although I believe the time is coming when we will meet the very conditions that you are speaking of. I want to relate an experience, however, that I had in Illinois. As inspector, I was familiar with the conditions at the mine, which was located at Cardiff. They were working two seams; the lower one was 12 ft. in thickness and worked on the room-and-pillar system, while the other was worked longwall, the coal being about 36 in. thick. In the longwall workings we never found any gas; but in the lower thick seam we were troubled with a good deal of gas. The longwall seam was worked from one side and the other thicker vein from the other side of the property.

When driving the rooms in the thick lower seam we could do exactly as Mr. Flynn has said and brattice the air to the face of the rooms; but when we started to draw pillars, falls would take place, and gas would accumulate in the hole above the fall and in the thin seam above the 12-ft. seam. I had to order the use of safety lamps where they were drawing pillars, as we could not direct the air current so as to keep the pillar workings clear.

I ordered them to use safety lamps entirely when drawing pillars. I was still afraid and the men who worked in the longwall mine, a mile away, were afraid of a gas explosion and they kept me in hot water for weeks there; and, for that reason, I required them, also, to put in safety lamps. If we could have done as Mr. Flynn stated and used a wing-brattice to clear out the gas from the top of those falls, it would have been the best thing to do, but that was not possible. I was always afraid of a fall bringing the gas down on the men.

Mr. Flynn—How thick was the cover or what was the depth below the surface?

Mr. Dunlop—The depth to the lower seam was 258 feet.

Mr. Flynn—Would it not have been better to have drilled a hole from the top and let the gas escape?

Mr. Dunlop—It would be impracticable to drill holes over all that section.

Mr. Flynn—Don't they do that in Pennsylvania?

Mr. Dunlop—It would require a great many holes.

Mr. Roderick—Is there any law in Illinois by which you can compel the operator to put holes down to drain off the gas?

Mr. Dunlop—No.

Mr. Flynn—You have a law compelling them to remove gas, haven't you?

Mr. Dunlop—Yes, from the working places only. If there is an accumulation of gas any where that is dangerous we are required by law to make it safe.

Mr. Burris (*Illinois*)—Did you require the men working in the longwall seam to use safety lamps?

Mr. Dunlop—Yes sir.

Mr. Bolt (*Illinois*)—I want to ask whether or not as inspector you do not have the power to insist that all gas be removed from mines where it is dangerous, in Illinois. Suppose a mine in your district generated gas and the accumulation became dangerous, would you not have the authority to compel the operator to remove the gas?

Mr. Dunlop—I have just answered that question; the law requires that the mine be made safe.

Conditions in New Mexico Mines

Mr. Beddow (*New Mexico*)—I just wish to state that we have a similar condition at Dorsey, N. M., to that described by Mr. Dunlop. We have a mine that generates gas, and when they commence pulling pillars the gas begins to accumulate. They are now removing that gas by the air current. The system they use there is a kind of block or panel system. They turn seven rooms in each panel, leaving pillars between the rooms and barrier pillars 150 ft. thick between the blocks or panels. They only pull six pillars in each block; the pillar in the first room on the intake side is left standing. After drawing the pillars back a certain distance and the gas shows up, they put up a brattice. There is a crosscut in the face of each room, and they have always managed to have plenty of air to keep the rooms free from gas. I have been over there many times and have never found any gas on any of my visits.

Experience in Very Gassy Mines

Mr. Williams—I possibly may have as much experience with safety lamps, mixed lights and real gassy mines as any man here; and as each one must express his opinion from his own standpoint, I might venture to say we have conditions in Pennsylvania where it would be impracticable and dangerous to work certain sections of the mines with open lights. In one mine that I superintended, we carried the brattice within 10 ft. of the face, and still, at the face, we could get an explosion in the lamp in either of the two corners of the chambers. That

was with the same company that Mr. Flynn is working for now. You could get a cap on the return air; a cap ½ in. high, with 200,000 cu.ft. of air passing in the mine. We had blowers that we could hear 300 ft. away.

During my term as inspector of the Connellsville region, I have seen large volumes of gas on falls, and it could not be removed without sinking boreholes from the surface. The method of mining is possibly 80 per cent. on the retreating system. They drive the entries to the boundary, leaving 84-ft. barrier pillars and with room pillars 10 ft. wide. Then they start back and draw the pillars on a regular fracture line. The first fall is not very high, but the second is higher and so on until the falls are so high they cannot get air over them and the only thing to do is to sink boreholes from the surface, to the top of the fall. In my present district, I have about 14 or 15 gassy mines; some are very gaseous and we could not work the entries, even if a brattice was carried to the face of the entry, without safety lamps. A current of 235,000 cu.ft. of air passes under a 6-in. water gage. The seam is not thick and we cannot get enough air to keep the faces clear of gas without the boreholes. The entries are driven wide, and the rooms are about 15 to 18 ft. in width, but in the lower corners we can get an explosion, at any time, in the lamp.

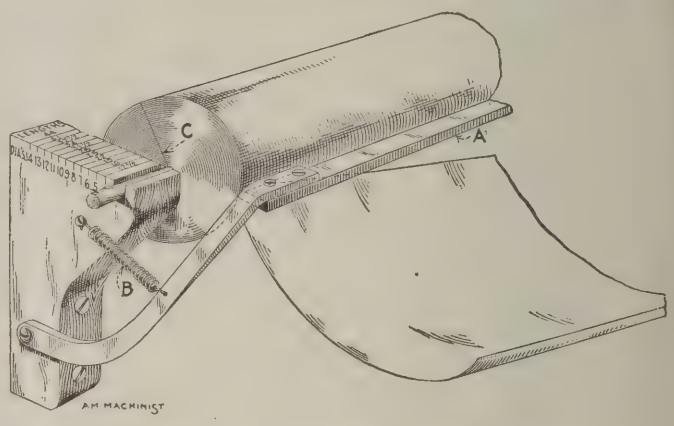
The law requires that, in all mines where safety lamps are used, men working on the return current must use safety lamps. It is strictly against the law to work with an open light, on the return side of any section of the mine where the safety lamps are used. I can realize the stand most of the members present are taking. They are basing their opinions on conditions at home, which is the best guide after all. Our firebosses examine every working place, without exception, all roadways and all falls adjacent to working places, twice each day. The mine foreman or his assistant also examines these places. When we find gas on the gob or the falls we take out everybody on the return side of the gob, as there is danger of the gas being ignited by a flaming shot or other cause.

Mr. Flynn—Is it not a fact that the H. C. Frick Coke Co. will not permit, under any circumstances, now, the use of open lights and safety lamps in the same mine?

Mr. Williams—That is the policy.

Mr. Dunlop—You have mentioned gaseous mines. Have you any mines where they can use mixed lights at all?

Mr. Williams—Yes. We have mines that are slope mines. A portion will be under light cover and on advancing into the mines the cover becomes heavier, and the conditions change. We are not requiring the use of safety lamps in those sections where we have never found gas or where the cover is light. We keep those air splits separate from the other sections of the mine and from the return air, and where we use safety lamps we keep a man to prevent an open light from going into those sections.



This closed the discussion.

In regard to the use of feed water which contains scale-forming ingredients, one principle should always be observed, and this is to precipitate as much as possible of the scale-forming matter before the water enters the boiler. It is a barbarous practice to reduce the thermal efficiency of boilers and run the risk of pitting and corrosion by the introduction of alkaline reagents into the boiler itself. Such an outofdate method is entirely unnecessary and should be avoided.

A Drawing-Paper Support

Rolls of drawing paper are usually mounted on brackets as shown in the illustration, and to avoid the irregular cutting and unnecessary waste usually present in the drafting room, the following device was adopted with good results.

The steel bar *A* across the front of the roll presents an edge against which the paper may be torn straight; this bar is held tight against the roll by means of the springs *B*. One end of a new roll is marked radially with a rough pencil mark as *C*. The readings on the bracket from the

Sketch of a Drawing-Paper Support

center out, are the lengths of circumferences corresponding to the existing diameter of the roll.

Observing first the position of the radial mark, any length required is approximated with little waste by means of the scales on the brackets, halving, adding, or doubling, as the case requires.—*American Machinist.*

Engineers' Society of Northeastern Pennsylvania

The Engineers' Society of Northeastern Pennsylvania held its 17th annual meeting in the banqueting hall of the Hotel Jermyn, Scranton, Penn., on the evening of Feb. 5. There were about 325 members present. President H. M. Warren remarked that the attendance at Scranton was larger than the record gathering at Wilkes-Barre, the year before.

The Scranton Engineers' Society a short while ago changed its name to that given above and about the same time it took on new life. As Mr. Warren declared, it has doubled its dues from $5 to $10 and has concurrently increased its membership from about 300 members to 409, despite all the prognostications of those who opposed the increase in annual charges.

It has also purchased a large dwelling, just back of the Y. M. C. A. building, and has fitted it for a club house. The charges of $25,000 for the building and $5000 for the remodeling have entailed a considerable burden on the society, and committees have been formed to wipe out both these debts.

E. R. Pettebone, the incoming president, regards his office as much a burden as an honor, a sure earnest of activity on his part and an evidence that he believes that much responsibility rests on him to perform diligently the duties of his office. The mayor, E. B. Jermyn, might cheerfully anticipate a membership of 1409, but E. R.

Pettebone set himself no standards for fear of disappointment.

Judging by the roster of speakers, one would not think that coal-mining engineers form the bulk of the membership. The toastmaster was W. D. B. Ainey, a member of the Federal House of Representatives and a delegate to the Hague Peace Congress. The principal speakers of the evening were: N. P. Lewis, chief engineer, Board of Estimate and Apportionment, New York City, who spoke on city planning, and Hudson Maxim, the inventor of explosives, who addressed the audience on "The Truth about our Peace and War Problems."

E. A. Jones, second deputy state highway commissioner, stationed at Scranton, spoke in place of E. M. Bigelow, and deplored the fact that the funds of the department did not permit of adequate support being given to the township officials in the repair of roads. In place of J. A. Holmes, the director of the Bureau of Mines, H. C. Reynolds addressed the society on the "Engineer as an Expert Witness." The speech-making ended at about 12:30 p.m.

The Answer

By Robert Lang*

A reply to Mr. Braley's poem "The Question," which appeared in "Coal Age," Jan. 31, 1914.

What has been done with our aged men,
Is a theme that has ever been sung.
But a question of greater moment is—
What has been done with the young?

When the fires of youth are all aglow,
And the world is moving fast,
Does the young man ever pause to think
That age will come at last?

That the hand of time gets a strangle grip
On the over-impulsive heart,
And the ardor of youth burns low and dies
Ere the body and spirit part?

Think not of age, my miner friend,
Or what will become of the old.
If you spend your years in a search of truth
You will safely enter the fold.

Mine Explosion Said to Have Been Caused by Acetylene Gas

Deputy Mine Inspector Gaffney of Ohio is reported as saying that the mysterious explosion in the Wheeling Creek mine, near Bridgeport, Ohio, was caused by the ignition of accumulated acetylene gas. After a careful investigation, Mr. Gaffney eliminated both firedamp and powder as causes of the accident.

It was discovered that two powder cans filled with refuse carbide from the lamps of miners previously employed in that part of the mine had been placed in this same chamber nearly two months before. By actual test, when the cans were taken out of the mine, the refuse carbide, under the same conditions that prevailed underground, gave off enough gas to ignite and cause a flame. It is believed that the unfortunate miner was killed by crawling into a chamber filled with the acetylene gas, which he ignited with the naked light he carried on his cap.

Chief Mine Inspector Davies was on the scene after the accident occurred, and stated that the case was one of the most remarkable he had ever experienced.

Ohio Anti-Screen Law Passed

The Green mine-run bill, which provides that miners shall be paid for all coal produced, and not permitting a screen to be used, was passed last week. The vote in the House of Representatives was 103 to 8, which shows the hopelessness of the contention of the operator against the measure. Only one amendment was embodied in the bill as it came from the Senate, and that was to make it effective in 90 days, instead of Oct. 1, 1914, as provided in the original draft of the bill.

Just what action will be taken by the Ohio operators is still a matter of conjecture. There are several courses open and the operators are considering the best one to follow. There is the referendum which can be used if sufficient signatures to a petition can be secured, but that is a long fight and then the voters of the state may decide to uphold the action of the legislature.

Another course is to violate the law and have the matter in the courts, where the constitutionality of the measure can be tested. This appears to be the most feasible course to follow.

The cost of changing the tipples in Ohio to conform to the requirements of the new law will be almost $1,000,000, it is believed.

Bosses To Be Nonunion

Eriton shaft, an operation of the Northwestern Mining & Exchange Co., an affiliation of the Erie R.R., went on strike Dec. 1, 1913, to compel a boss fireman to join the United Mine Workers of America. The following proposition was submitted by the company to the workmen and was adopted by them on Jan. 22, after the men had been idle eight weeks.

To All Employees at Eriton Mine—We are ready to resume work at Eriton mine, just as soon as it can be gotten in shape for resumption of work, with the distinct understanding, however, that you restore our rights and conditions to the same basis as they were when you suspended work and closed our mines, and with the further distinct understanding that the following positions and the men filling the same, now or hereafter, shall be exempt from membership in the United Mine Workers of America.

The positions referred to are as follows: Superintendents, mine foremen, assistant mine foremen, firebosses, motor bosses, machine bosses, boss firemen, weigh bosses and master mechanics.

We agree, however, that the boss fireman who is now a member of your organization, may, if he so desires, retain his membership therein until Apr. 1, 1914. We agree further, that neither the members of the United Mine Workers of America nor our officials will hold any personal prejudice against any man employed at Eriton mine.

If the above proposition is accepted by the men at Eriton, those whose places are in condition for immediate resumption, can begin work just as soon as arrangements can be made for proper day forces to take care of same, which arrangements will be rushed with all possible haste.

JOHN H. FULFORD,
General Superintendent.

Du Bois, Penn.

This proposition was accepted with but four dissenting voices in a meeting where 500 were present.

*Superintendent, Galloway Coal Co., Garnsey, Ala.

The Close of the Indianapolis Convention

EDITORIAL CORRESPONDENCE

SYNOPSIS—The scale committee urged a 5c. increase in miners' wages, and a 10 per cent. increase for day labor, inside and outside, and for dead work. Despite the attempts of the radical element to call for a 10c. increase, the decision of the convention was in favor of demanding only a 5c. raise in the pay of the miners.

We confess to a sense of increased confidence in the United Mine Workers of America as a result of the Indianapolis convention. In every large body, it is a foregone conclusion that some men will be found with peculiar views, anarchistic, socialistic and syndicalistic, but the convention in its closing hours sailed quietly into port under the steady hand of John P. White. He has winked and connived at the radical element and so has been deserving at times of the severest censure, but at heart he really *believes* in being fair in his dealings, even when his acts belie his statements. When he does what is wrong, he does it as subordinate to the rough-and-tumble element and not as leader of his organization.

THE SCALE ADOPTED

The "scale," which was adopted as read, is as follows:

1. That all coal be weighed before being screened, and be paid for on a mine-run basis.
2. That we demand a flat 5c. a ton increase at the basing point.
3. A 10 per cent. increase on all dead work, yardage and day labor.
4. A uniform workday and wage scale for all classes of outside and inside day labor.
5. A proper adjustment of all machine differentials at the basing point.
6. That we demand a complete check-off for the miners' organization through the company's office.
7. That we demand that all the local inequalities and internal differences be referred to the various districts affected for settlement.
8. We demand that where the price or regulation of powder is made a contract provision that union-made powder shall be furnished.
9. That the miners work only one-half day on Saturday.
10. That the company shall pay drivers for time from taking charge of stock until the company receives the same.
11. We demand that our contract shall be in effect for two years.

THE MINE-RUN PROVISION

That part of the scale which will arouse strong opposition is the first section: That all coal be weighed before being screened and be paid for on the mine-run basis. As Illinois operators and many in Pennsylvania now run their plants under contracts of this kind, and as Ohio mine owners are about to be compelled to adopt this method by legislation, it is probable that they will use strong pressure to make the operators in other states accept the new arrangement of their affairs.

The almost universal use of machines favors the miners' contention. There is little call for excessive use of powder after the coal has been undercut to the requisite depth, and lumps of coal can be just as easily lifted, and thrown or built up on the car as they can be shoveled in as slack. The objection will partly come from the smaller operator, who has no money to buy machinery and hesitates to accept the risk of adding to his indebtedness. Much opposition will come from those operators who are unable to remove pillars by machinery.

The main difficulty will arise in determining the true equivalent between a mine-run scale and one based on lump coal only. The fear that the miners intend to be unreasonable in the making of this change, and the idea that the miners want to obtain pay for their slack equal to that now paid for lump coal, makes the change in scale rating exceedingly unpopular among the operators, and with good reason.

The scale committee consisted of the following members: Van Bittner, District 5, chairman; Joseph Pope, District 12; John Moore, District 6; William H. Houston, District 11; Lawrence Garrigus, District 8; John T. Dempsey, District 1; Patrick Gilday, District 2; Thomas Kennedy, District 7; James Matthews, District 9; Martin Flyzick, District 10; W. H. Rodgers, District 13; Alex Howatt, District 14; John McLennon, District 15; Thomas Cairns, District 17; J. E. Smith, District 18; Pat Cary, District 19; J. R. Kennamer, District 20; P. R. Stewart, District 21; A. G. Morgan, District 22; L. B. Walker, District 23; Joseph Smith, District 24; George Manuel, District 25; Henry Drennan, District 27; L. C. Rodgers, District 29.

Casdrole, of the Pittsburgh district, moved to amend the second demand so as to increase the miners' wages 10c. instead of 5c., but J. W. Jarrard, of Johnson City, Ill., came to the defense of the scale committee's report. President White spoke for a demand which would not disturb industrial peace. He did not believe in trading back and forth, and thought the convention should ask for what it wanted and expected to get.

THE KENTUCKY MINERS WANT THEIR WAGES RAISED

The Kentucky miners, through George Baker, wanted the convention to assist the miners of his district, No. 23, which was surrounded by nonunion fields. He said: "We are working for 16⅔c. a ton less than the miners in adjoining states, and the rate for dead work and day labor is 35 to 60c. a day less." Eventually a resolution was passed pledging the miners in southwestern Kentucky that the union would use every endeavor to unionize nearby and competitive coal fields.

President White strongly opposed a suspension pending an agreement with the operators. He placed the blame on them for the report that such a suspension would occur. He said they urged it only because they wished to rid themselves of surplus stocks.

INDIANAPOLIS DISCIPLINED FOR FAVORING OPEN SHOP

The vote to choose a convention city favored St. Louis. Indianapolis received only 19 votes, but Kansas City was a strong competitor, being only beaten by 80 votes. It is thought that as a result of a referendum, the number of delegates will be considerably reduced by the next convention. Each district will elect as many delegates as there are thousands of members, and the delegation will not be elected by the local unions. But there seems no sense in arranging to meet at St. Louis and waste by travel what is economized by reduction in numbers.

The president's salary was raised from $3000 to $4000 per annum, and the secretary-treasurer received at the close of the meeting an increase in salary from $2500 to $3300. The stipend of the editor of the *Mine Workers' Journal* was also raised from $1500 to $2000 per annum. The international board members' pay when employed was raised from $4 per day to $125 per month.

Editorials

Should Strikes Occur?

Speaking at the last winter session of the Coal Mining Institute of America, Harrington Emerson, the well known efficiency advocate said:

A strike seems to me not only a preventable, but a ridiculous, stupid thing like the sinking of the "Titanic" or the wrecks on the New York, New Haven & Hartford R.R.

Adverse comment on this bold and perhaps largely untrue statement was made by several of those who discussed the paper. We reproduce it, however, because it is so confident that it focuses one's attention and makes one question just how much truth there is in it.

We cannot overlook the fact that the United Mine Workers of America is organized for strife and to a degree its continuance depends on its discovering wrongs, real and fancied, for which it can demand a remedy. On the whole, however, a more enlightened spirit would demand that the union be kept like a modern army as an insurance against oppression rather than for aggressive purposes. There are men who irk at paying life and fire insurance, because the need of either is so rare. Men tire of paying union dues for the same reason, but nevertheless a prudent man will consider the best union one which protects its members without a strike, without even a suspension. The army fulfills its purpose most successfully when it does not fire a shot.

We must also remember that the object of the direct-action advocates is to foment perpetual strife and arrange for a strike whenever the operator is least desirous of such an annoyance. Such people, we believe, will soon tire of the strenuous course they have marked out. In fact, there is even now a lull which seems to indicate that syndicalism has exhausted its advocates, physically, mentally and morally.

The toll of hate is heavy on its followers, deranging their digestive organs, preventing restful nights and overthrowing the reason. Economically also, it impoverishes at least the rank and file. It cannot continue forever. Orgies of hate have arisen again and again in history and after a period, longer or shorter, died away, not without, however, leaving grievous scars.

As for the coal operators we must say that to some extent they are to blame for the frequency of strikes. They do not, it is true, meet and willfully decide to risk a reduction of wages every year or two. If the miners would show signs of being willing to continue at work at the old figures there would be no desire on the part of the operators to seek a reduction. An attempt to change the scale downward is such an unsettling factor in business that the operators as a whole are almost always opposed to it.

They do, however, frequently ask for a reduction, in order to countervail a demand for an increase. It is a foolish practice, and to be deplored. It brands the operator as seeking something which is unreasonable. With the cost of living going up, can any operator anticipate that a strike will end with a reduction of wages, without creating the most bitter of feelings and the maledictions of the public?

We have previously advocated that wage increases be based on the index of increased cost of living. We would suggest that contracts be made for five years on that basis, increases being made year by year proportional to any increase in the cost of living, plus a certain percentage, say a half per cent. per annum, justifiable on the ground that the workingman should receive not only the power of purchase of similar goods year by year, but should be able to buy more products as the labor of producing them decreases with the introduction of machinery.

Let the operators rest their wage scales on science, let them advertise in the press their method of basing those wages, and the people will be obliged to admit that they have an extremely plausible case. But asking for reductions at every readjustment puts them on a level with an Arabian peddler, and is unworthy of the one-price merchandizing of this present century.

Will the time ever come that the operators will be able to celebrate like the United States and Great Britain, a centenary of peace? Some individual companies there are, which have never had a strike, and perhaps a time may come when the hand and the head in the industrial being will never enter into conflict.

Our Mercantile Marine

Ex-Governor McCorkle pleads for a mercantile marine in the article we publish today, and says it would materially increase the foreign coal trade of the United States. The foreign mercantile shipping is a favorite matter for discourse in the halls of Congress and in daily journalism. We cannot blame Mr. McCorkle for humming a tune he has heard played so often and so alluringly.

But as a matter of plain fact the British and Scandinavian marines have been denationalized for years. They would carry American coal with just as good grace as British, so long as they could earn a liberal profit. The only argument for building a national mercantile marine we can see is that it will be a help to our navy in time of war.

In peace we can hire foreign ships to carry our coal if there is money in the traffic; if there is none, let us compel the representatives, senators and newspaper men to undertake that obligation without any bounty. The argument for the mercantile marine is purely naval and its validity stands or falls on that score alone.

During the British coal strike of March, 1912, business in Europe sank to an extremely low ebb and a number of steaming vessels were without cargoes. They came over to America and loaded up with coal for the Mediterranean and they were willing to accept almost any figure for the service.

Conditions in Europe improved as the strike ended; the price of coal fell in the Mediterranean ports and only with difficulty could American coal continue to pay the freight charges existing. But to make matters worse, ships were attracted to Europe to engage in their old

trade and the shipping rates to the Mediterranean went up to their former level. Immediately the cry was raised that the Briton was at his perfidious tricks and was raising rates on cargoes in order to keep the coal of this country from proving its worth in the market.

It is the old story and should we subsidize a mercantile marine, we can well write its sequel. Just as soon as such an organization is formed, it will engage in the trade most profitable to it; some ships will carry alien products to foreign ports and the jealous metropolitan dailies will say the ship owners have been bribed or coerced into neglecting the needs of the nation and favoring foreign coal.

Our Foreign Trade

We commence to publish today a remarkable address delivered by W. A. McCorkle, an ex-governor of West Virginia, before the West Virginia Mining Institute. We have read many articles on the foreign trade, and found quite frequently that they did not seem to confront the main difficulty, which may be thus stated: Any country which will not *buy* quantities of bulky foreign articles cannot expect to *sell* abroad a hold-filling product like coal, which is mined on every continent and in nearly every country.

It seems strange to the man on the street that America can supply Europe, Asia and Africa with grain, meat and machinery and cannot sell coal, though the greater part of the three continents have inferior fuel and in some parts none at all. It seems stranger to him to hear that because we ship so many products to Europe is the reason why our coal is excluded and stranger yet it seems that our large export trade with Europe is the cause for coal being shipped from Europe to America in times of industrial conflict in this country.

But it is clear that in order to transport coal to Europe cheaply, we must have a return cargo for the vessel and that the lading on the return voyage must be capable of standing a heavy freight charge or the transportation rate will be unduly heavy. The British coals find the return traffic good; the American fuels discover it almost entirely lacking and so despite the lower price at the coast, the coal of the United States remains without transatlantic and Pacific demand.

Ex-Governor McCorkle realizes some of these facts and it is a wonder he does not see that conditions are similar all over the world except in North America and the eastern littoral of South America. We have a big commerce with the Caribbean Sea; from Cuba, iron ore; from Honduras, mahogany and other woods; from Guatemala, bananas; from the Bermudas, potatoes and onions; from Venezuela and Porto Rico, coffee. So there is no difficulty in the carriage of coal to these ports or others near-by, such as Colon, especially as boats can safely go light to that port over waters that are still. What is true of Panama is therefore no indication of conditions beyond it.

It is a wonder that Mr. McCorkle does not realize that nearly all the Pacific is more a prospective purchaser than a probable seller to the United States and as its freights will always be larger west than east, coal will find no opportunity for carriage. We must compliment him, however, on knowing that the direction of transportation will depend not so much on the relative distances but on the cost of coal along the route.

But disagreeing with Mr. McCorkle, we must advise West Virginia against too great a faith in Panama as a market. It is further away, it is true, from the center of ocean freightage in Europe than Suez and may, therefore, sell more coal to European ships as soon as its traffic is as large as that of the Egyptian canal. But for many years its tonnage will be much smaller than that of Suez.

And it is significant that Egypt imported from Great Britain during 1911, the last prosperous year of which we have record, only 3,476,780 short tons. The following year probably as a result of the strike in the British coal fields only 3,276,924 short tons were purchased. Malta and Gibraltar took together 860,754 short tons in 1911 and 916,410 short tons in 1912.

The tonnage sold to Gibraltar, Malta and Egypt per year is less than the increase in output of the state of West Virginia in 1913 by about 1½ million tons. If West Virginia is hoping for a rapid growth on the basis of actual Panama trade, we are afraid a disappointment is in store. The foreign trade of Great Britain is a prize worth seeking. It absorbed 85,889,710 tons of coal in 1913, some of it being shipped in manufactured forms such as coke and coalite. This is equal to the output of West Virginia and Indiana in the same year. If all this foreign trade could be absorbed by the United States it would add 15% to its business, as large an increase as would normally be added by five years of domestic advance.

However, it begins to look less significant when we state that three counties in Pennsylvania, Fayette, Westmoreland and Luzerne, produced in aggregate 10,000,000 more tons in 1912 than Great Britain exported in 1913. Eventually, the British miners with their notions of restriction of hours, limitation of output, minimum wage and a hundred other crippling demands will give us all the foreign trade of Great Britain. In this they will be aided by the natural conditions, greater mining depth, irregularity of coal beds and depletion of coal resources. But we may be sure, on the other hand, that Great Britain will not lose this trade for many years.

We do not think that the Panama canal will have a great effect in stimulating the coal trade. Certainly a liberal discount can be made on the rosy anticipations of our would-be exporters. Meanwhile, it is amusing to read the alternate hopes and fears of the British technical press. Now they expect to keep the eastern coast of America supplied with their "incomparable coals" and then the trade balance shifts and the Yankee peril looms up like the Genie of the bottle.

The arguments, if such they may be called, for a rearrangement of the balance of coal trade in the world have been made mainly by visionaries and pessimists and we do not look for any sudden readjustment at the present time.

The United Mine Workers of America, at Indianapolis, adopted a new section to the constitution providing that sick, accident and death benefits may be established in any district, sub-district or local union, whenever a majority of the members of the respective bodies so determine. This aroused much opposition from Delegate Summerville, of Ohio, who said that had a benefit fund in his local lasted another six months, all the members would have been sick.

A Model Town in West Virginia

The Lackawanna Coal & Lumber Co., which owns, in fee simple, about 30,000 acres in one tract in Boone County, will begin an extensive coal operation there in the late spring or early summer.

This new development will be on Hopkins Fork, a branch of the Laurel Creek, the latter being a tributary of the Coal River. It is about nine miles from Seth, which is on the Coal River division of the Chesapeake & Ohio R.R. The new town will be called Griffith, being so named for the vice-president of the company. The new town of Griffith will approach the model village as nearly as possible. The plans for town and tipple have already been completed.

In laying out the town, the company has followed newly approved ideas in sanitation and hygiene and has sought the advice of sociological experts. It is expected that there will be about 300 houses for the miners. These will be erected on plots large enough to give each family a fair-size lawn and adequate garden space. They will be roomy and all of them will have running water in them and will be lit with electricity or gas.

Due attention will be paid to living conditions. Near the tipple there will be a large bathhouse for the miners, and each miner will have his own locker. There will also be two club houses. A hotel will be provided for the accommodation of travelers. A skating rink will also be built and, near it, a moving-picture theater. Here the company officials expect to show many pictures that will illustrate the latest methods in mining and will also help to teach the miners how accidents may be prevented. But films of a purely entertaining nature will not be forgotten.

The railroad from Seth to Griffith, about nine miles, has been completed about a year and the company has been using it in its lumber operations. It is estimated that there are 300,000,000 tons of coal in this tract. The officers of the company are W. L. Connell, of Scranton, Penn., president; J. K. Griffith, of Pittston, Penn., vice-president; T. J. Foster, of Scranton, treasurer, and David Connell, of Scranton, secretary.

Recent Legal Decisions

Right of Individual Bondholder to Sue—Provision in a mortgage or deed of trust securing bond, prohibiting individual bondholders from bringing foreclosure suit on default, does not prevent suit by them to recover defaulted interest, without foreclosure, unless such provision extends to such suits, as well as suits to foreclose, by virtue of its express terms. (St. Louis Court of Appeals, Muren vs. Southern Coal & Mining Co., 160 Southwestern Reporter 835.)

Mine Operator's Responsibility for Co-Employee's Negligence—Under the laws of Missouri, a coal-mine owner is liable for injury to a mine resulting from a defective condition negligently created by a fellow miner, as where the latter leaves a dumped empty car so near a track that another miner is injured, without fault on his own part, in driving by it. (Kansas City Court of Appeals, Martin vs. Farmers' Coal Co., 160 Southwestern Reporter 816.)

Mine Operator's Duty to Furnish Props—Duty to Warn Minor Employee—The requirement of the laws of Kentucky that mine operators shall furnish props to secure the roofs of their working places extends to the supporting of draw slate, as well as permanent mine roofs. This duty is not affected by the fact that a miner is employed under contract to remove coal at a fixed rate the ton. It is actionable negligence to permit an inexperienced boy miner to work under dangerous conditions against which he is not warned. (Kentucky Court of Appeals, Interstate Coal Co. vs. Trivett, 160 Southwestern Reporter 728.)

American Institute of Mining Engineers Organize Anthracite Section

A subdivision of the American Institute of Mining Engineers, to be known as the Pennsylvania Anthracite Section, was organized at the Sterling Hotel, in Wilkes-Barre, Saturday evening, Jan. 31. Among those present at this initial gathering were Charles F. Rand, president, and Bradley Stoughton, secretary of the national organization. About 50 other engineers and company officers of the different anthracite corporations attended the meeting, and signified their intention of joining this new section of the Mining Engineers' Institute. R. V. Norris, of Wilkes-Barre, was chairman of the evening. Among those who spoke were H. M. Chance, chairman of the Coal and Coke Committee; Prof. J. W. Richards, Lehigh University; W. J. Richards, vice-president of P. & R. C. & I. Co.; R. J. Foster, Scranton; J. D. Davis, Kingston; and C. F. Huber, Wilkes-Barre. An executive committee was elected and is composed of the following members: R. V. Norris, chairman; W. J. Richards, R. J. Foster, Edwin Ludlow, C. F. Huber, Douglas Bunting, F. A. Hill, Chas. Enzian and J. M. Humphrey.

Those present were:

Thos. Thomas, E. R. Pettebone, H. G. Davis, H. M. Crankshaw, J. B. Warriner, H. W. Montz, Chas. F. Rand, Bradley Stoughton, H. M. Chance, Geo. P. Gallagher, Wm. Griffith, S. J. Jennings, E. C. Lee, W. D. Owens, Frank A. Hill, W. J. Richards, G. W. Engel, Rufus J. Foster, F. A. Gleason, Jos. W. Richards, W. R. Crane, Alfred G. White, H. H. Ashley, Douglas Bunting, Wayne Caruthers, E. M. Chance, F. M. Chase, W. F. Dodge, Chas. Enzian, M. S. Hachita, G. T. Haldman, Chas. F. Huber, J. M. Humphrey, John Lloyd, F. J. McMahon, R. V. Norris, Wm. E. Shearman, A. C. Stahl, Paul Sterling, P. Wainer, T. L. Welles and F. E. Zerbey.

Cost of Machine Mining in Pittsburgh District

The following table of the cost of machine mining in the Pittsburgh district was compiled by Jesse K. Johnston, vice-president and general manager of the Pitcairn Coal Co.:

COST OF MACHINE MINING PER TON

1897 Cutting		1912 Cutting		Per Cent. Advance
Rooms	$0.075	Rooms	$0.1244	65.86
Entry	0.105	Entry	0.1644	56.57
1897 Loading		**1912 Loading**		**Per Cent. Advance**
Rooms	$0.28	Rooms	$0.5356	91.29
Entry	0.34	Entry	0.6537	92.27

Miners' Convention Cost $130,000

The Indianapolis convention lasted about 13 working days and cost about $130,000. The funds of the union, therefore, must now be about $150,000, or roughly 40c. per member. The advocates of direct action are strongly opposed to unionism, because they say it tends to conservatism, and they are right. Surely when the union men realize how their funds are continually depleted, they must understand, and in a degree sympathize, with the capitalist, and must realize that the large aggregations of capital, with their appalling figures, shrink into insignificance when the whole population serves as a denominator in determining the individual possession.

A good feed pump requires from 1 to 1¾ per cent. of the steam generated to deliver the necessary amount of feed water.

Discussion By Readers

How to Buy Coal

Letter No. 2—The several discussions of this question in past issues of COAL AGE have led the ordinary reader to believe that our present B.t.u. method is obsolete and beset with inaccuracies and that the system is on the decline. This may be true, but not to an alarming degree. It is safe to say, however, that its worth is not declining any more rapidly than it was taken up by the bituminous coal industry in general. It is necessary for the small as well as the larger consumers to have some standard and some method by which to gage the quality of their product, and for the want of something better the chemist is compelled to resort to this determination to arrive at some sort of a tangible figure.

The insurmountable obstacle to this proposition, as stated by Mr. Burrows, Vol. 4, p. 866, is in sampling. Accordingly, I think that the statement that the B.t.u. method is obsolete should be modified and the direct cause of imperfection be attributed to sampling, where it properly belongs, and not to the chemical method employed to determine the heating value of the coal. The correct sampling of all coals, ores, cement, etc., is one of the most difficult propositions known to the chemist, and while he may err on a few samples, yet his average analysis of a product, for a period of 365 days, is sufficiently correct for most commercial computations.

Periodic sampling of a small lot of coal and subsequent thermal determinations may not reveal the true value of a coal; but where a tonnage of several hundred tons a day is used, and the material sampled after plant crushing, the sample and analysis ought to be considered a fairly accurate indicator of the heating value of the coal. I am informed that large consumers do not accept analytical results from samples taken directly from the cars.

It is stated that the railroads and government have discontinued the heat-unit specifications, which, no doubt, is the result of being now in possession of complete chemical information, after years of investigation, of all the coal fields of any importance in this country. Assuming that given coal seams and districts produce coal quite uniform in quality, it is possible, now, to purchase the coal by trade names with fair satisfaction, and without entailing the cost of analyses. Shall we assume that the scientific force and value of analyses have been displaced because of this connection with politics? The analysis of a coal should be a shield for a public officer, whereby he can avoid suspicion of showing partiality in giving contracts of public tenders.

It is universally acknowledged that coal-burning apparatus must be adapted and proportioned to suit a particular fuel; but must not the character of this particular fuel, in the first place, be determined by chemical and physical tests? The chemical analysis should never be the final word as to the value of a coal, yet its chemical composition must be known, to some extent, for the benefit and help it will prove in the correct operation of a power plant.

In regard to inconsistencies in coal specifications, it is assumed that in modern specification systems where large tonnages are used, suitable provisions are made for every element and the behavior of the fuel in the furnace.

The trouble of the small consumer and dealers who handle two- or three-carload lots and probably get their supply from a number of different mines and districts in using this method should not condemn its use in other operations.

Specifications, however, should not work a hardship on the smaller dealer. Let the mine operator carefully ascertain the grade, adaptability and quality of his product; and then sell and guarantee it for the purposes for which it is best suited.

If we cannot reasonably rely on the present B.t.u. method why pay any attention to the ash and sulphur results. If we discard the one, which is dependent on the others, then our whole system of coal analysis is incorrect. Until a better method than the present is devised, I think that the present one is relatively accurate for assessing the thermal value of a bituminous coal, under proper sampling conditions.

J. V. FREEMAN.

Joliet, Ill.

The Mine-Run Problem

Letter No. 1—I have read with much interest the two articles analyzing the Ohio Mining Commission's report, COAL AGE, Jan. 24, p. 167; and Jan. 31, p. 196, and discussing the question of paying the miners for the nut and slack coal on what is known as the "mine-run system." It occurs to me that there should be some equitable solution of this vexing problem.

The discussion of the question in Ohio has resulted in the passage by the House, of the "Green Anti-Screen bill." There are many views as to the wisdom or expediency of such legislation. It appears to me, however, but just and right that the miner should be compensated for the handling of the finer coals, such as nut and slack, that pass through a 1¼-in. screen. In Kentucky, these "fines" amount to from 35 to 40 per cent. of the total coal mined and loaded on cars.

There are many cases where operators pay for the coal mined on a mine-run basis, but the price paid is generally about 42 per cent. less than the rate paid for screened coal. In innumerable cases, the payment for mining on this basis has imposed grievous hardships on the operator, as many miners seek to secure greater weight by an excessive use of powder in the mining of the coal. In every mine, there is a certain class of miners that will follow this practice, regardless of the large increase of screenings produced thereby, in order to increase their own daily output and lessen, to some extent, the labor of mining. Where this practice is followed, the impurities of the coal, slate and clay are reduced to such fineness that the smaller grades of coal are comparatively valueless, except as they are further prepared by washing. Few of the

smaller operations can afford the increased cost of washing these lower grades of coal and, except for coking operations, the process is hardly justifiable.

In my opinion, the rate of payment on a mine-run basis should be adjusted by a careful determination of the proportion and price of the two grades of coal. At the present time, the screenings, nut and slack, bring in this market 50c. per ton, while the lump coal is sold at $1.65 per ton. If we assume the price of mining screened coal is 87½c. per ton, the mining price for screenings, if taken proportionately, would be 1.65 : 0.50 : : 0.875 : 0.265; or, say 26½c. per ton. In this manner, it seems to me that an equitable price could be fixed for the payment of mining coal, on a mine-run basis. The adoption of some such system would go far toward settling the seemingly never-ending dispute. The miner would have no incentive to practice "hard shooting," producing thereby an excessive amount of dirty screenings. On the contrary, his interests would be in line with those of the operator, in producing larger quantities of lump coal, and, as a result, greater harmony would prevail.

S. F. Rock,
Civil and Mining Engineer.

Richmond, Ky.

The Certificate Law

Letter No. 18—It has been with great interest that I have read the different opinions expressed in relation to the interchange of certificates issued by the mining departments and examining boards of different coal-producing states and provinces. Being the holder of three first-class certificates issued, respectively, in Pennsylvania, Alberta and British Columbia, Canada, my experience may be of interest to others.

I strongly favor the adoption of a plan that would bring about an interchange of certificates of competency for the positions of mine manager, mine foreman, fireboss and hoisting engineer, in all states and provinces where the conditions of mining are similar. Such a plan would, however, require a uniform standard of examination. Without such a uniform standard and the limitation to similar conditions in mining, such an interchange of certificates would not be advisable. In my opinion, it would not operate in the interest of safety for the men and the security of mining property.

To make my meaning clear, I would say it would not be policy for an examining board to grant a certificate of competency to a mine foreman, for a gaseous mine, when his present certificate entitles him to hold that position in a nongaseous mine only. The same difference of condition should be considered in respect to dust. While one mine may be practically free from dust, or contain dust that is almost inert, the dust of another mine may be highly inflammable and explosive.

Again, assuming like conditions of mining and an equal standard of examination, the practical experience of the candidate should be a large factor in determining his qualification to take charge of a mine. I believe that a man of long experience who has duly qualified and obtained his certificate in one state, is better fitted to hold the same position in another state than the man who has succeeded in passing the examination in that state, but who has only the amount of experience required by law to enable him to secure a certificate. The man of large experience is a more valuable man and will be able to operate the mine with greater safety and advance the interests of the company more certainly than the man who has yet much to learn.

In regard to the life of certificates of competency, I am of the opinion that all officials in coal mining should be examined at least every five years, up to the age of 50 years, when I think they should be exempt from further examination. I believe that such periodical examination would be a great stimulus to efficiency; as mine managers, mine foremen and firebosses would then have to keep posted in reference to mining matters, as the examinations would naturally keep pace with the improvements made each year in coal mining. In my opinion, periodical examinations should be strongly advocated by all mining corporations, as it would provide more intelligent and efficient service and increase the safety of the men and security of the mines.

J. W. Powell, Supt.,
Cottonwood Coal Co.

Windham, Mont.

Letter No. 19—In connection with the discussion of the certificate law, I would like to draw attention to a common practice in mines that is very annoying to a conscientious fireboss and one that cannot but prove harmful and even dangerous in many cases. By drawing attention to this practice, which is more or less prevalent in all mining districts, it may be possible to obtain some remedial legislation that would go far toward eliminating the evil.

I refer to the fact that a fireboss who is thoroughly qualified and competent to discharge the duties of his office, and aims to fulfil the requirements of the mining law of the state impartially in the performance of his duties, and is governed by a single motive only, namely, to insure the safety of the men and the security of the property in his charge, may and often is intimidated and forced to make a report that is, to say the least, inconsistent with his knowledge and convictions.

Too often it happens that the fireboss is approached by a mine committee, whose conduct is influenced and regulated most largely by the careless, indolent and meddlesome element in the mine. It is this class of workers that breed trouble and do more to endanger the lives of their fellow workers than any other condition common to mining.

The consideration of these facts, which are well known to all familiar with mining conditions, must convince any unprejudiced mind that we have need of the enactment of a law making it a penal offense for any man or committee of men to interfere with the fireboss in the performance of his duties in the mine.

A Constant Reader.

Caldwell, Ohio.

Letter No. 20—In my opinion, the mine foreman is the most logical man to determine the nature of the dangers present underground. For this reason, he should have the knowledge and practical experience that will enable him to foresee dangers that may arise and detect any dangerous conditions that may already exist in the workings. On the mine foreman rests the responsibility of thus detecting and removing all dangers reported or known to exist in the workings.

A conscientious foreman, having at heart the "safety first" idea, will not fail to visit every portion of the mine as often as his duties and time will permit. The feeling of his responsibility will take him to the working face, into the gob and all abandoned places, and cause him to travel constantly the airways, haulage roads and traveling ways throughout the mine. Therefore, if anyone knows the true condition of the mine, it is the foreman. His knowledge and acquaintance with underground conditions are more intimate than that of the superintendent, the general manager, or even the mine inspector.

Referring to the work performed by the state mine inspector, his time is too limited for him to secure more than a general knowledge of each mine visited. He inspects No. 1 mine today, No. 2 tomorrow; and his time, for the next 60 or 90 days, is spent in other fields. On his return, he goes hurriedly through the mine, makes certain suggestions and notes the general conditions for the report he must make to his chief. It is absurd to think that the mine inspector with his many and varied duties, in connection with the special investigation of accidents, attendance upon coroners' inquests and the compilation of reports, can possess a knowledge of any particular mine equal to that of the mine foreman.

Because the mine foreman, of all other persons, is the man in closest and constant touch with the mine workings and the conditions existing therein, he should not only be a good moral and truthful person, but he should have the very best training possible to fit him to assume the duties and responsibilities of his position. He should be a man of sunny disposition that will enable him to gain and hold the good-will and respect of every man in his charge, as well as that of his superiors.

In view of these responsibilities, a mine foreman should never be allowed to take charge of a mine until he has become fully acquainted with the conditions existing within and around that mine. No argument is needed to prove that a man capable of assuming these responsibilities will have little or no trouble in passing an examination in any state in which he may seek employment. In my opinion, any man, with ambition to pass an examination for a certificate of competency, if he is a true man, will keep himself posted on mining matters sufficiently to enable him to pass an examination in any state, as that is his reasonable duty that he owes his fellow workers and the company who employs him. For my own part, I have never seen the time yet when I could not study and read. I am convinced that it is best for all concerned that each state examine its own foremen and firebosses.

Oliver Springs, Tenn.

Study Course in Coal Mining

By J. T. Beard

The Coal Age Pocket Book

Potential Values of Different Airways—In order to show the resisting power of airways of different lengths of those sizes in more common use, the following table has been prepared, showing the potential value of each airway, as calculated by the formula

Potential of airway $$X = \frac{a}{\sqrt[3]{klo}}$$

Following this is another table giving the potential values of different circulations, by which is meant the circulation of different volumes of air under different pressures or water gages. A comparison of the potential values in these two tables will serve to show what circulation can be obtained in airways of given size and length when properly arranged and unobstructed.

TABLE—POTENTIAL VALUES FOR DIFFERENT AIRWAYS

Size of Airway	Length of Airway (ft.) 1000	2000	3000	5000	8000	10,000
	Potential Value of Airway					
4x10 ft.....	485.3	385.0	336.5	283.8	242.6	225.2
4x12 ft.....	557.0	441.9	386.2	325.7	278.5	258.5

Potential Values of Different Circulations—The circulation of a given quantity of air in a certain airway or mine requires a certain pressure or water gage, which determines the "potential of the circulation."

In the following table, the potential of the circulation is calculated by the formula

Potential of circulation, $$X = \sqrt[3]{\frac{Q^2}{p}} = \sqrt[3]{\frac{O^2}{5.2\ w.g.}}$$

TABLE—POTENTIAL VALUES FOR DIFFERENT CIRCULATIONS

Water Gage (In.)	Pressure (Lb per sq.ft.)	Volume of Air Circulated (cu.ft. per min.) 10,000	15,000	25,000	50,000	75,000	100,000
		Potential Value of Circulation					
6.....	31.2	147.4	193.2	271.6	431.1	564.9	684.4

The Coal Age Pocket Book

A comparison of the two tables on the preceding page shows that to pass a current of 25,000 cu.ft. per min. through an airway of 5x8 ft., 3000 ft. long, including the return will require, practically, a 3-in. water gage. This is ascertained by observing that the potential value of an airway 5x8 ft., 3000 ft. long, as given in the first table, is, say 345. Then find the water gage corresponding as nearly as possible to this value, in the second table, in the vertical column for 25,000 cu.ft. per min. The potential of the circulation of this air volume under a 3-in. gage is, say 342, showing that a 3-in. gage is a little in excess of what is required to circulate 25,000 cu.ft. of air per minute in a 5x8-ft. airway, 3000 ft. long, including the return.

Effect of Splitting on Mine Potential—As a mine is developed and its airways extended, it becomes impracticable to carry the air in a single current throughout the entire length of the airways, as the water gage then increases directly as the length or distance of air travel. To avoid this difficulty, the air must be divided or "split" one or more times; so that there will be two or more separate currents in the mine. Each of these currents is called a "split of air," or simply a "split."

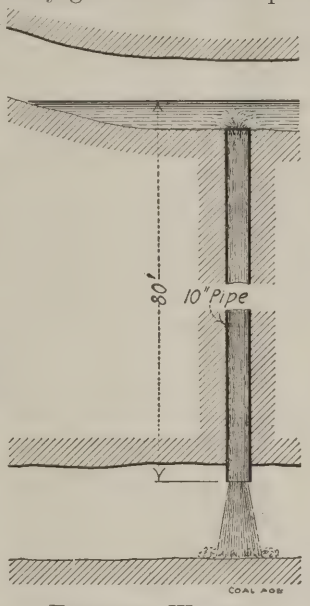
It should be observed that dividing the current does not change the total rubbing surface(s) in the mine; but the area of passage (a) is increased in proportion to the number of splits or currents. Since s = lo, the formula for potential of airway may be written as mine potential; thus,

Mine potential, $$X = \frac{a}{\sqrt[3]{ks}}$$

Since the rubbing surface (s) and the coefficient (k) are constant and the area (a) increases in proportion to the number of splits or currents, the potential (X) increases in the same proportion. Therefore, any of the airway potentials of the first table can be multiplied 2, 3, 4, etc. times according to the number of splits or currents employed.

For illustration, suppose the airways of a mine are 5x10 ft. and have a total length, including return, say 10,000 ft.; and the required circulation is 100,000 cu.ft. per min. The velocity of the air should not exceed, say 500 ft. per min., in the airways. This will require a total area of passage of 100,000 ÷ 500 = 200 sq.ft. But the sectional area of these airways is 5 × 10 = 50 sq.ft.; and there must, therefore, be 200 ÷ 50 = 4 splits or currents to comply with the conditions named. The potential value, as given in the table, for a single current, is, say 275; and the mine potential for four splits is, therefore, 4 × 275 = 1100. By referring, now, to the second table giving the values of the potential of circulation, it is found that a potential value of 1100, in the circulation of 100,000 cu.ft. per min. shows a water gage between 1 and 1½ in. The true value may be found by interpolation, if desired, and is 1.46 in.

The potential value of any desired circulation of air, as compared with the potential value or "potential factor" of the proposed mine or airway is thus seen to have an important practical value that commends it to all students of mining.



Inquiries of General Interest

Flow of Water in a Vertical Pipe

The accompanying sketch is intended to represent an accumulation of water in an overlying abandoned seam; and it is desired to know how many gallons of water per minute will flow down a 10-in. pipe, into an underlying seam, assuming the pipe is vertical and its mouth 80 ft. below the surface of the water in the upper seam.

DRAINAGE.

Seanor, Penn.

FLOW OF WATER VERTICAL PIPE

In this case, the gravity head, 80 ft., is opposed by three heads; namely, the entrance head (ho) required for the water to enter the pipe and due directly to the crowding of the stream lines, as illustrated in the accompanying figure. Beside the entering head, there is the friction head (hf) due to the resistance of the pipe to the flow of the water, and the velocity head (hv) absorbed in producing the velocity of the water in the pipe.

The velocity head and the friction head have been fully explained, COAL AGE, Vol. 3, pp. 541 and 970. Experiments have shown that if the mouth of the pipe is flush with the floor of the seam, there being no bell-shaped entrance, the entrance head is practically one-half of the velocity head. Therefore, these three heads are expressed as follows:

Entrance head, $$ho = 0.0013\frac{G^2}{d^4}$$

Velocity head, $$hv = 0.0026\frac{G^2}{d^4}$$

Friction head, $$hf = \frac{l\,G^2}{800\,d^5}$$

The sum (h) of these three heads may therefore be written

$$h = \left(0.0039 + \frac{l}{800\,d}\right)\frac{G^2}{d^4}$$

which may be written

$$h = \frac{1}{800}(3.12\,d + l)\frac{G^2}{d^5}$$

From the last equation, calculating the flow of water, in gallons per minute (G), through a pipe whose diameter is d, we have

$$G = 20\,d^2\sqrt{\frac{2\,dh}{3.12\,d + l}}$$

Substituting the values, h = 80 ft., l = 80 ft. and d = 10 in., we have for the flow of water, under the assumed conditions,

$$G = 20 \times 10^2\sqrt{\frac{2 \times 10 \times 80}{3.12 \times 10 + 80}} = say\ 7500\ gal\ per\ min.$$

Study Question--Timbering

I have been studying some of the back numbers of COAL AGE, and would like to ask for an explanation of the factor, 4/3, contained in the answer to the first question on p. 268, Vol. 2. The question is as follows:

"What load will break a white-pine beam 10x12 in. and 14 ft. clear span? Assume the beam is supported at both ends and uniformly loaded."

The answer gives the following calculation:

$$\frac{4}{3} \times 7500\,\frac{10 \times 12^2}{14 \times 12} = 85{,}700\ lb.$$

I do not understand the factor 4/3, and cannot find any table that gives the fiber stress as 7500 lb. per square inch, as stated in the answer to this question. Instead, I find it given as 450 lb., on p. 103 of the Coal and Metal Miners' Pocket Book. The formula I have always used does not give much more than one-half the above load.

Breaking load $$\frac{10 \times 12^2}{14} \times 450 = 46{,}300\ lb.$$

Kindly explain my difficulty.

"X."

Seanor, Penn.

In the first place, the rule quoted by correspondent gives the breaking load, in pounds, for a rectangular beam "loaded at the center," and the question states the beam is "uniformly loaded." For a uniform load the result must be doubled, which gives, by correspondent's method, 92,600 lb.

The formula given in COAL AGE, Vol. 2, p. 268, is a more accurate formula for determining the breaking load of a rectangular beam uniformly loaded. This formula is based on the fiber stress of the material, which, for white pine, is 7500 lb. per sq.in. This is an average value for a good quality of white pine, based on the reports of the U. S. Agricultural Department, Division of Forestry.

The factor, 4/3, has been determined, by experiment, for rectangular beams supported at each end and uniformly loaded. The two formulas will be seen to practically agree, remembering that the length of span in correspondent's formula is given in feet, while in the COAL AGE formula it is given in inches. Thus, comparing these two formulas, we have

$$\frac{4}{3} \times \frac{7500}{12} = 833$$

This is somewhat less than 2 × 450 = 900, which would be the value used by correspondent, corrected for a uniform load. The difference in these results lies in the value taken for the fiber stress.

Examination Questions

Miscellaneous Questions

(Answered by Request)

Ques.—What are the duties of a mine foreman?

Ans.—Upon the mine foreman devolves the duty of seeing that the mining law is carried out in every particular. It is his duty to be thoroughly familiar with the state law in all its details and to see that the mine is operated in compliance thereto. The mine foreman must devote his entire time to the supervision of the mine. He must direct all operations underground; keep watch over the ventilation of the mine; inspect all machinery and appliances used in ventilating, pumping, hoisting and haulage and the means used for lighting and draining the mine. He must inspect all working places, haulage roads, air courses and traveling ways as frequently as practicable, and where his duties and limited time will not permit of a daily inspection of every part of the mine, he must see that this is properly done by competent assistants.

The mine foreman must make regular measurements of the air traveling in the mine and record the results of these measurements in a book kept for that purpose. He must superintend all work, see that it is performed in a proper and workmanlike manner; make suitable regulations for safety; and maintain discipline. Besides supervising the daily output of the mine, he must report all accidents to the mine inspector, attend all coroners' inquests and do all in his power to maintain safe conditions in and around the mine.

Ques.—What weight of coal dust does it take to cause an explosion?

Ans.—This question cannot be answered definitely, inasmuch as the explosive condition, with respect to fine coal dust in suspension in the air, will depend on a number of conditions, such as, the fineness and inflammability of the dust; the gaseous condition of the mine air, its temperature and hygrometric state; and the presence or absence of other gases that would increase or decrease the explosiveness of the mixture.

Theoretically, it is estimated that 1 lb. of finely divided coal dust, held in suspension in the air, in the absence of other gases than that produced by the burning of the dust, will render explosive 2440 cu.ft. of air measured at a normal temperature and pressure. This corresponds to practically 0.006 oz. of coal dust per cu.ft. of air.

Ques.—Assuming that an air current containing gas at its most explosive point, has a velocity of 400 ft. per min. in a 6x8-ft. airway; how much air must be added to this current to make the gas it contains 1 per cent. of the mixture?

Ans.—The sectional area of the airway is 6x8 = 48 sq.ft. The volume of air in circulation is, then, 400 × 48 = 19,200 cu.ft. per min. The air current being at its most explosive point contains 9.46 per cent. of gas. The volume of gas in the current is, therefore, 19,200 × 0.0946 = 1816.32 cu.ft. If this volume of gas is 1 per cent., the total volume of the mixture of gas and air will be 1816.32 ÷ 0.01 = 181,632 cu.ft. per min. The volume of air that must be added, therefore, is 181,632 — 19,200 = 162,432 cu.ft. per min.

Ques.—A colliery shaft 16 ft. in diameter and 250 fathoms deep is used entirely for the purposes of ventilation. Taking the coefficient of friction as 0.005, calculate the entire frictional resistance of the shaft and the horsepower expended when an air current of 250,000 cu.ft. per min. is passing.

Ans.—The sectional area of the shaft is 0.7854×16^2 = say 201 sq.ft. The velocity of the air current is 250,000 ÷ 201 = say 1250 ft. per min. There being 6 ft. in one fathom, the depth of the shaft is 250 × 6 = 1500 ft. The perimeter of the shaft is 3.1416 × 16 = 50.266 ft., nearly. The rubbing surface of the shaft is, therefore, $s = 50.266 \times 1500$ = say 75,400 sq.ft. Since the value of the coefficient of friction given is probably per thousand cubic feet of air, the velocity must be expressed in thousands of feet per minute; and is, in this case, 1250 ÷ 1000 = 1.25 thousand feet per min. The resistance of the shaft is then

$$R = k\,s\,v^2 = 0.005 \times 75{,}400 \times 1.25^2 = 589+ \textit{lb.}$$

To find the horsepower absorbed in passing the air through the shaft, this resistance must be multiplied by the velocity of the current, and that product, divided by 33,000; thus

$$H = \frac{589 \times 1250}{33{,}000} = 22.3\ \textit{hp.}$$

Ques.—In a mine working 312 miners, 49 daymen and 22 mules, how many cubic feet of air should be in circulation when 80 per cent. of the miners are at work in the mine?

Ans.—The total number of men at work is 0.80 (312 + 49) = say 290 men. Assuming a nongaseous mine and allowing 100 cu.ft. of air per min. per man, and 500 cu.ft. per min. per mule, the total quantity of air in circulation should be 290 × 100 + 22 × 500 = 40,000 cu.ft. per min.

Ques.—What material would you consider the best to use for building an overcast in a mine that is producing marsh gas in dangerous quantities; stone, brick, iron or wood? Give reasons.

Ans.—Although stone, brick and iron are often used for this purpose, wood is generally preferred, for the reason that a wooden overcast is more easily repaired when broken or displaced by the force of an explosion than one built of stone, brick or iron. The destruction of a brick or stone overcast will generally result in a heap of rubbish, while the twisted iron, in that type of construction, is always difficult of removal. On the other hand, the broken timbers of a wooden overcast can be quickly cut or sawed out and removed. In many cases, however, the wooden planks and timbers are not broken but merely displaced, and the air bridge can be quickly repaired. The principal objection to the use of wood for building an overcast is that the wood is combustible and therefore an element of danger.

Coal and Coke News

Washington, D. C.

The demand for active Government participation in the operation of mines still continues. The sub-committee of the House Committee on Mines which was authorized to investigate the Colorado coal strike has already gone to the field of action and is engaged there in beginning its work.

Meantime the Industrial Relations Commission which has apparently felt the necessity of undertaking something in line with the demands that have been made by Congress has also, it is understood, voted to start upon an inquiry into the mining conditions.

In order to push these efforts further, Senator Borah in a long speech delivered in the Senate on Feb. 4 made an elaborate attack upon the methods adopted by the State of West Virginia for the purpose of repressing the disorders in the coal mining regions.

Incidentally he said that the vast majority of coal mine workers favored peaceful methods in urging their purposes and that labor leaders who preached lawlessness were enemies to the man who toils and to the cause of better conditions, better pay and happier homes. He contended, however, that all guarantees of constitutional government must absolutely be insisted upon in the case of labor troubles just as in every other case where there was conflict between two elements in the community.

Rate Hearings Concluded by Shippers

Bituminous coal men have finished their case against the proposed increase of rates suggested by the railroads, occupying the bulk of Monday, Tuesday and Wednesday, Feb. 2, 3 and 4 in their argument. It is understood, however, that they will be permitted to add further data in reply to the carriers if it should be found that the latter have presented fresh information that is of a nature calling for additional data.

Among those who have testified most effectively during the latter part of the hearings for the bituminous coal shippers was H. H. McCue of the Pittsburgh Coal Co. who argued that the results of the Boileau case would be entirely neutralized and a much greater harm inflicted on the shippers if the proposed rate increase were permitted. The Canadian Manufacturers Association has also protested on the ground that the proposed advance would certainly be followed by a similar advance over Canadian lines.

HARRISBURG, PENN.

One of the many problems that have arisen in connection with the workings of the income-tax law, and one that vitally interests many people of the anthracite and bituminous regions of this state, is that which is involved in determining whether coal royalties are to be considered as income, or as the proceeds of a sale. The contention is made by holders of the fee that since when the coal is exhausted, the property no longer exists, the royalties should rightly be considered converted capital assets and not income.

The following opinion has been given from the office of the Commissioner of Internal Revenues at Washington, D. C.

. . . This office holds, that under the provisions of the income-tax law, Section 2, Act of Oct. 3, 1913, royalties, in a measure represent income to the individual receiving the same and must be so returned; but the owner of the fee from which the coal or ore is received may deduct from the income, to make good the depletion of assets, an amount not to exceed 5 per cent. of the gross value of the output at the mine, that is, the f.o.b. value at the mine.

What proportional amount received from royalties which represent gains and profits and what amount can be considered conversion of capital assets is not, as yet, finally determined, and until a definite rule is adopted relative to this matter, royalties will be considered an income and return will be made in accordance with the above suggestions.

A prominent attorney, who has taken this matter up with the Federal department in the interest of clients who have royalty bearing coal holdings, explains how this rule would work out, by the following example: If the gross value of the output at the mine is $3.80 per ton, which is a fair rating, then the discount allowed for depletion of assets would be 5 per cent. of that amount, or 19c. for each ton. If the owner of the fee held interests which netted him 30c. on each ton, then 19c. would represent the amount on each ton allowed for depletion, and would be regarded as the converted capital assets. The balance, 11c., would be considered income. If the output for the taxation period was 10,000 tons, then the individual's royalties would be $3000, of which $1100 would be regarded as income and $1900 as converted capital assets.

The Pennsylvania Files an Answer

The answer of the Pennsylvania R.R. Co. to the complaint of the Manufacturers' Association, of Lancaster, regarding the rate for the transportation of bituminous coal from the Clearfield district to Lancaster was filed recently with the Public Service Commission. The Baltimore & Ohio and the Philadelphia & Reading have also filed petitions for leave to intervene, as party defendants.

The coal-shipment-rate question has been before the commission for some time and expert advice has been called in on the question of rates from the Schuylkill region (anthracite) to Philadelphia. A report will soon be made.

In its answer regarding the rates charged for moving bituminous coal to Lancaster, the Pennsylvania R.R. denies that the rate is unjustly discriminatory against Lancaster, and asks that the complaint be dismissed.

The Baltimore & Ohio says that if the rates of the Pennsylvania R.R. are reduced it will be necessary for the Baltimore & Ohio either to reduce its competitive rates from the Meyersdale or Somerset region to Lancaster; or, if it maintains its present rates, to allow its shippers to be placed at a disadvantage in competition with shippers from the Clearfield region on the Pennsylvania R.R.

The Reading likewise asserts that if the Pennsylvania R.R. is compelled to make a reduction the Reading would be compelled either to maintain its present rate and thus lose a great part or all of its traffic in bituminous coal to Lancaster, or to reduce its rate to Lancaster and to the numerous intermediate points which are embraced in the rate group.

A reduction in rates to all such intermediate points would greatly decrease the revenues of the Reading and would result in a far-raching disturbance of its rates to eastern Pennsylvania points.

PENNSYLVANIA

Anthracite

Shamokin—All collieries of the Susquehanna Coal Co. in this region closed down Feb. 4 until Feb. 9, 5000 employees being rendered idle. Mild weather and a slump in the anthracite coal trade is given as the reason for the order.

Fire, which broke out in No. 16 vein of the Buck Ridge colliery, on Feb. 2, spread with considerable fury with the result that it was necessary to flood the workings. It is supposed that the fire resulted from defective dynamite. Over 100 miners were laid off for an indefinite length of time.

Wilkes-Barre—The court of Luzerne County, on Feb. 4, appointed the following to serve on the board of mine inspectors' examiners for Luzerne and Carbon Counties: George P. Gallagher, of West Pittston, and Charles S. Miles, of Wilkes-Barre, mining engineers; Benjamin McEnenay, of Exeter, Thomas J. Evans, of Nanticoke, and Patrick Dougherty, of Lansford, practical miners. The men succeeded are John W. Berry, Robert A. Quinn (vice-president of Susquehanna Coal Co.), mining engineers; George L. Walker, Plains, William Toner, of Larkesville, and Frank Schmear, of Lansford, miners.

Pottsville—An explosion of dynamite killed two men on Feb. 2, in the stripping of the St. Clair Coal Co., and was caused by a charge of dynamite left unexploded from Jan. 30, with which a drill came in contact when a laborer drilled into the hole unaware of the presence of the explosive. Mine Contractor Frank Denning and an unidentified Italian were killed instantly.

Bituminous

Outcrop—Alleging that John Heron, mine foreman of the Crystal mines of the United Connellsville Coke Co., had permitted Frank Fordyce to fire a blast from "solid" while other employes were in the immediate vicinity, Mine Inspector I. G. Roby recently made information against Heron charging him with violation of the mining laws.

New Bethlehem—Frank Williams & Co. have leased their upper Hillville mine at New Bethlehem in the Allegheny

Valley to A. W. Williams, of Pittsburgh. It has been idle some months, but will start up at once. It has a capacity of 400 tons, but will be pushed up to 600 tons soon.

Connellsville—It is reported the H. C. Frick Coke Co. is negotiating for the purchase from J. V. Thompson, of Uniontown, of 7000 to 10,000 acres of coal in Greene County at $500 to $800 an acre, the deal involving approximately $5,000,000.

Pittsburgh—Shipments of coke from the Connellsville region over the Pennsylvania lines to Pittsburgh and West were lighter in January than in the same month last year. Official figures show that 29,244 cars of coke were shipped in the initial month of 1914, while during the same period of 1913 the shipments aggregated 49,472 cars. This is a decrease for the present month of more than 20,000.

WEST VIRGINIA

Charleston—The coal business in West Virginia appears to be, at the present time, more slack than for years. Mines in the Clarksburg-Fairmont region are working but a small portion of the time, while some of the smaller concerns have closed down temporarily.

Kingwood—The Kingwood-Cleveland Coal Co., a corporation with main offices in Cleveland, Ohio, has recently purchased a large tract of coal land at Snyders' Crossing, where a siding is now being constructed from the main line of the West Virginia Northern to the company's holdings. Tipples and power houses will be erected in the near future as well as dwellings, it is believed. It is the expectation to be producing coal in large quantities at an early date.

Colliers—Officials of Brooke County are seeking some plan whereby they may disarm striking coal miners who are known to carry weapons, but are being careful to remain on their own property and are hence not amenable to the state law prohibiting the carrying of fire arms.

VIRGINIA

Virginia City—The mines of the Virginia City Colliery Co. were recently sold to George W. Lambert and W. T. Williams, and it is understood that the new owners will spend considerable money electrifying and otherwise improving the property so as to double its present output of coal.

ALABAMA

Oakman—The Atlas Coal Co. recently leased its mines near Oakman to J. C. Lilick, of Ensley, and Joseph Thompson, of Adamsville. Messrs. Lilick and Thompson are experienced and practical mining men.

KENTUCKY

Sebree—About 30 employees of the Sebree Coal & Fuel Co. have gone on strike on account of the refusal of the company to pay every Saturday night, instead of on alternate Saturdays, as the rule has been for a number of years. The mine is idle.

Henderson—Negotiations are under way by the Deep Water Coal & Coke Co. for a site on which a modern steel tipple and complete loading equipment for the company's barges will be erected. It is understood, however, that nothing definite has yet been determined with reference to the location of the site, as some difficulty is being experienced in securing land at a reasonable figure.

Dawson Springs—It is reported that Claud Gentry will open up a small operation near here to work a 58-in. vein of No. 6 coal which he has discovered.

Providence—The Harris Coal Co. has filed a voluntary petition in bankruptcy in the Federal court at Owensboro, Ky. Liabilities are fixed at $16,859, while assets are said to amount to $13,645. The Madisonville Savings Bank is the largest creditor of the company.

OHIO

Bridgeport—The 450 miners employed in the Wheeling Creek mine of the Lorain Coal & Dock Co. who have been idle since the explosion which killed Frank Hora have agreed to resume work. The order from the State Mining Department that only oil should be used for lighting purposes caused the men to go on strike. Their contention is that it was coal gas and not acetylene which caused the explosion.

Columbus—The pamphlet to be issued by J. M. Roan, safety superintendent of Ohio mines, to start the campaign of "safety first" will be published in seven different languages in order to reach all of the miners of the Buckeye state. Mr. Roan will write a personal letter to every miner injured, advising him of the way to prevent such accidents in the future.

East Liverpool—Eighty miners employed by the Card & Prosser Co., of West Pittsburg, walked out of the mine at that place recently because of a reduction in the wages for dead work. Steps are being taken to adjust the difficulties.

Cannelville—The announcement is made that mine No. 38 of the Maynard Coal Co. will be closed permanently, but this is denied by the company officers located at Columbus. The mine is to close temporarily because of lack of orders.

INDIANA

Petersburg—Nearly 1000 acres have been leased in Pike and Warren counties for surface coal mining. The veins are 3 to 7 ft. thick lying at a depth of 5 to 40 ft. It is estimated surface coal is available in 6000 acres in the two counties.

Sullivan—Clifford Botts, a machine operator at the Reliance mine, was recently fined $10 and costs for failing to provide break throughs in rooms and entries at a distance of at least every 45 ft., and Sam Watts, mine boss, was fined $10 and costs for failing to properly ventilate the mine.

Clinton—It is confidently predicted by officials of the Bunsen Coal Co. that provided there is no cessation of work in April, due to the wage-scale agreement, that one million tons of coal will be produced from the two Bunsen mines known as the "million-dollar twins," located five miles south of this city. Although expensively equipped, these mines have not thus far equaled in output some of the other coal mines in the Clinton field.

ILLINOIS

Marion—W. L. Dunsten and Hogan Williford have purchased the mine east of here known as the Pittsburg Big Muddy. It is not likely they will operate this property unless they can get a connection with the Iron Mountain R.R.. Its present connection is on the Illinois Central.

Irving—The Peabody Coal Co. is having some trouble with its mine at Taylor Springs. About a year ago a fall closed up one of the main entrances, shutting off a considerable amount of equipment, and damaging the farm of E. T. Richards. Recently another squeeze occurred, this time in the third and fourth entries and men have been warned to keep out of this portion of the workings

Chicago—Swift & Co. and three railroads were recently indicted by a grand jury in the U. S. District Court on charges of rebating and soliciting rebates. The packing firm alone faces a possible maximum fine of $1,200,000 under the charges. The other defendants were the Pennsylvania R.R., the Chicago & Northwestern R.R., and the "Panhandle."

IOWA

Knoxville—Workmen employed in digging a deep well on the Inebriate Hospital grounds report that the drill penetrated an 8-ft. vein of good coal at a depth of 290 ft. It is said that a shaft will be sunk and the deposit worked by the hospital inmates before the end of the present year.

MISSOURI

Moberly—In an accident recently at the Elliott mine, five miles south of this place, electrician Barman was instantly killed and two assistants seriously injured while repairing the ropes of the cage. One of the ropes broke, permitting the cage to drop to the bottom of the mine.

KANSAS

Courtland—A report that a 6-ft. bed of coal has been discovered near Courtland, brought a number of operators to the scene. If the veins prove as rich as expected, active operations will begin shortly.

Beulah—George & Lawler have secured 3500 acres of coal land, north of Beulah, and have begun prospecting. This is a comparatively new territory, but is believed to be rich in coal. They have leased also 1800 acres south of the tract referred to, to the Hamilton Coal & Mercantile Co., which is conducting experiments with a view of beginning operations in the near future.

ARKANSAS

Fort Smith—The strike of miners in the employ of the Central Coal & Coke Co. was terminated shortly after the walkout. About 1000 men were out, affecting eight mines. The miners charged that the company failed to abide by the decision of the district arbitrator, who upheld the claims of four men for compensation during a period of alleged enforced idleness. The company ultimately agreed to pay the claim and the miners returned to work.

Suit to annul the lease of the Pennsylvania Mining Co. on 100 acres of coal land in Johnson County has been filed by

J. T. Bailey and Van R. Norris in the United States court. The plaintiffs allege the company has failed to pay royalties of 10c. a ton on coal mined since 1911, and that the corporation has ceased using the land except to extract coal from adjoining territory. Both charges, the petition asserts, automatically annul the lease.

OKLAHOMA

Bartlesville—A. M. Parsons has secured a number of leases on coal land near Bartlesville, Okla., and will begin testing at once. The contracts provide that thorough tests must be made within six months, and that operating must begin within a year from the date of the leases.

COLORADO

Pueblo—It is reported upon military authority that but for the congressional investigation, the militia could be removed from the southern coal fields at once. It is alleged that about one-third of the original number of strikers are left in the tent colonies, and these are said to be leaderless and without heart. They have been urged on by false hopes and now the congressional investigation is holding those that remain together.

Colorado Springs—It is believed that Colorado Springs will be one of the cities in this state where the federal committee to investigate the coal strike will hold hearings. This belief is based upon advices received from Washington.

RECENT COAL AND COKE PATENTS

Improvements in Coal Conveyors. L. Hyve, of Dorignes, near Douai, Nord, France, 4700 of 1913.

Coal Jigger. C. Simon, Essen-on-the-Ruhr, Germany, 1,082,102, Dec. 23, 1913. Filed Sept. 4, 1912. Serial No. 718,550.

Improvements in and Relating to Coal Washing Plants. R. Thomson, Lilybank, Reid St.; Burbank, Hamilton, Scotland. 4451 of 1913.

Mining Machine. A. H. Gibson, assignor to Ingersoll-Rand Co., New York, 1,082,318, Dec. 23, 1913. Filed Nov. 18, 1908. Serial No. 463,211.

Improvements in Apparatus for Washing Coal and Other Minerals. W. Habets, Montegnee, Belgium, and A. France, Rue de l'Esperance, 223, Liege, Belgium. 17,012 of 1913.

A New or Improved Method of and Means for Screening or Grading and Conveying Coal, Coke and Other Material. R. Benson, Riverside, Middleton, St. George, Durham, and Head Wrightson & Co., Ltd., 28,115 of 1912.

PERSONALS

R. F. Rogers, formerly of the Rogers-Garlick Coal Co., has been appointed assistant general manager of the Blue Ash Coal Co.

J. W. Dean, formerly mine foreman of the Barker Nos. 2 and 3 mines of the Continental Coal Corporation, has been appointed mine inspector over the 15 mines of the same company. His special work will be looking toward further safety of the company's employees.

O. P. Gothlin, who has been connected with the Ohio Public Service Commission since its formation has resigned his position as head of the traffic bureau and will travel in Florida for a time. Later he may be connected with the Interstate Commerce Commission. Mr. Gothlin is recognized as a traffic expert.

H. D. Mason, Jr., in charge of the United States mine-rescue car No. 4, now at Pittsburg, Kan., recently submitted a report showing the results of the recent tour of Arkansas and Oklahoma, which was interrupted by the Dawson disaster. One hundred and sixty-six men took the full rescue course, according to the report, while 36 more took partial courses. Nearly 4000 persons visited the car on the tour.

F. J. Durdan has been appointed general sales agent of the B. S. Hammill Fuel Co., and is opening offices in the new Marine Bank Building. He was a former Buffalo coal man, but was for some years general sales agent of the Monongahela River Consolidated Coal & Coke Co., previous to the consolidation with the Pittsburgh Coal Co.

OBITUARY

John H. Jones, general coal freight agent of the Philadelphia & Reading Ry. Co., died at his home, 356 Church Lane, Germantown, Philadelphia, on Feb. 4, from heart disease. Mr. Jones was born Jan. 26, 1837, in Norristown, Penn. In 1861 he enlisted in the 81st regiment of Pennsylvania Volunteers and served until April, 1865, on the staff of General O. O. Howard. He entered railroad service in 1865, and in 1880 was appointed general coal freight agent of the Philadelphia & Reading Ry. In 1890 he was made special agent in charge of the United States Census for the Department of Mines and Mining.

CONSTRUCTION NEWS

Charleston, W. Va.—Extensive coal development will be undertaken by the Lackawanna Coal & Lumber Co. on a 30,000-acre tract of land in Boone County, West Virginia, early in the summer. It is proposed to develop a model town to be called Griffith.

Rockwood, Penn.—The Bradenburg Coal Co. has closed down its mine east of Rockwood, due to slackness of orders. The State Line Coal Co. has also laid off many of its miners until about Apr. 1. In the meantime, needed repairs will be made to the plant and several mining machines will be installed.

Columbus, Ohio—According to an announcement of the Ohio Public Utilities Commission steps will be taken soon to secure new equipment for the Detroit, Toledo & Ironton R.R. The shippers along that route have been hampered by lack of equipment and motive power as the road is in the hands of a receiver. Steps are being taken to refinance the road.

Columbus, Ohio—The announcement is made that the Norfolk & Western R.R. Co. will build a third track from Portsmouth to Columbus in order to take care of the increasing coal traffic from West Virginia to the lakes. The Chesapeake & Ohio R.R. Co. will build a bridge across the Ohio River at Sciotoville and thus a portion of the tonnage from that road can be diverted to the Hocking Valley Ry.

Grafton, W. Va.—The Winona Coal & Coke Co. with a mine located at Coffman, four miles from this city, is contemplating extensive improvements in the spring. This firm is now renting its coke ovens from another company, but is arranging to construct 60 ovens of the most improved type. Another mine opening will soon be made, and about 20 miners' houses, together with a power plant, were recently completed.

Martins Ferry, Ohio—The Barton Coal Co. is planning to remodel its present tipple on the St. Clairsville branch of the C., L. & W. division of the Baltimore & Ohio R.R. to take care of about 800 acres of coal to the southwest of the present development. The tipple will be remodeled with a viw to handling a larger daily tonnage.

McDonald, W. Va.—Twenty-two coal mines in the vicinity of McDonald in the New River field are to be electrified under plans which have been worked out by the Randolph-Means Co., of Pittsburgh, Penn. Contracts have been made with the West Virginia Power Co. for central-station current and arrangements are being completed to dismantle the individual power plants.

Greensburg, Penn.—The Randolph-Means Co. has contracted for the electrification of the Keystone Coal & Coke Co.'s Keystone Works at Greensburg, where an isolated-power plant will be discontinued and central-station power will be substituted. The latter will be supplied by the West Penn Power Co.

Greensburg, Penn.—The Greensburg Coal Co. is extending the electrical equipment of its mine and is installing an electric mine hoist to be operated on alternating current. This latter will be in operation shortly. This machine is believed to be the first installation of any importance of this type to be placed in the Pittsburgh district.

Robertsdale, Penn.—Extensive improvements are being made at the works of the Rock Hill Coal & Iron Co. at this place. A 500-hp. plant, including engines and generators, is being installed to operate the mine on alternating current. Contracts have been placed with the Ridgway Dynamo & Engine Co. for engines and generators.

NEW INCORPORATIONS

Chicago, Ill.—The Western Coal & Dock Co., of Chicago, has dissolved.

Frankfort, Ky.—The Belcourt Coal & Mining Co. of Webster County has increased its capital from $3350 to $5079.

East Chicago, Ind.—The Wisconsin Lumber & Coal Co. has increased its capital stock from $25,000 to $100,000.

Chattanooga, Tenn.—The Tennessee River Coal & Coke Co. has been incorporated with a capital stock of $125,000, to develop coal.

Indianapolis, Ind.—The Oak Hill Coal & Mining Co., Vermillion County, and the Summit Mining Co., of Bloomfield, have dissolved.

Barbourville, Ky.—The Hazardtown Coal Co. has been organized with a capital of $30,000. The incorporators are W. M. Jones, O. C. McClung, and J. B. Eversole.

Providence, Ky.—The Washington Coal & Coke Co. has been organized with a capital stock of $3000. The incorporators are Henderson Foxwell, James A. Foxwell and I. Foxwell.

Marissa, Ill.—A certificate of dissolution of the Borders Coal Co. has been filed in the recorder's office. This is one of the oldest firms in the county, and the dissolution came as a surprise.

McAlester, Okla.—The North McAlester Coal Co., of McAlester, has been incorporated with a capital of $5000. The incorporators are Richard E. Jones, Walter Cunningham and Rosy Jones, all of McAlester.

Marion, Ill.—The Economy Coal Co. has been organized with a capital stock of $60,000 for the purpose of mining, buying and dealing in coal and fuel. The incorporators are H. G. Ferrell, S. H. Goodall and G. B. Campbell.

Lexington, Ky.—The Carnahan-Hudson Co. has been organized, with a capital stock of $50,000, by Robert T. Carnahan, of Louisville, and George K. Graves, Leonard G. Cox and Charles N. Manning, of Lexington. The company will purchase and develop mineral and timber lands.

Albany, N. Y.—A charter has been granted to the Seiler-Blanchard Co. Inc. The capital stock of the company is $25,000, and the offices will be located at No. 1 Broadway, New York City, and at Binghamton, N. Y. This firm will handle a well-known line of anthracite and bituminous coal.

Washington, Penn.—A charter has been filed for the Lindley Coal Co. The principal incorporators are William S. Morehead, Pittsburgh; John S. McKelvy, Jr., of Wilkinsburg, and William F. Knox, of Ben Avon. The company will engage in coal mining, and its principal offices will be located in Pittsburgh.

Welch, W. Va.—The Cumberland-Campbell Coal & Coke Co. has been organized with a capital stock of $25,000. The chief works will be in McDowell, W. Va., and Harlan County, Ky. The incorporators are James B. Flanagan, of Welch, Ely L. Glade, of Chicago, J. M. Clay, of Louisa, Ky., J. W. Waldron and Thomas J. Flanagan, of Welch.

Charleston, W. Va.—The Acme Corporation of Parkersburg has been organized for the purpose of operating mines, drilling for oil, holding water rights, developing and selling electricity. The capital stock is $250,000, of which $2000 has been paid. The incorporators are S. D. Camden, C. C. Martin, Thomas Logan and W. W. Van Winkle, of Parkersburg, and W. W. Mills, of Marjetta, Ohio.

INDUSTRIAL NEWS

Chattanooga, Tenn.—The Tennessee River Coal Co. is preparing to reopen its mines near Chattanooga, which have been closed down for more than a year.

Evansville, Ind.—It is announced here that seven more coal mines in western Kentucky will be acquired by the Deep Water Coal Co., of Pittsburgh. This firm recently took over 17 coal mines in western Kentucky and one mine in Newburg, Ind.

Belleville, Ill.—The mine of the Belleville Colliery Co., formerly known as the Lattmann mine, was sold recently to satisfy judgments and a chattel mortgage. It was purchased by Ben Gundlach for $11,000. The judgments against the colliery company were for wages due miners employed.

Youngstown, Ohio—It is estimated that the Pennsylvania R.R. spent for locomotive fuel last year $11,187,448; the Baltimore & Ohio expended $6,926,745; the Lake Shore, $3,926,888, and the Michigan Central, $3,323,535. The Lake Shore spent more for fuel than for repairs to engines.

Pineville, Ky.—The Pineville Coal Co. has purchased 1346 acres of coal land on Straight Creek and will establish a plant for a daily capacity of 1500 tons of coal. The equipment will include retarding conveyors, shaker screens, electrical machinery, etc., and contemplates the expenditure of about $100,000.

Lansford, Penn.—The work of removing the large culm bank at Lansford is progressing rapidly, and it is expected that within a year, the ground which has been occupied by this refuse heap for more than 60 years will be divided into building lots. A scraper line is being installed to clean up after the steam shovel.

Monongahela, Penn.—Negotiations are under way for the sale of approximately 500 acres of coal land in Followfield Township by the Joseph Rider heirs, and others, to the Wanner-Leonard Coal Co. This firm operates the Leonard mine at Fayette City; also a mine at Brownsville. The main offices are in Cleveland, Ohio.

Moundsville, W. Va.—A deal has been consummated whereby Samuel Dorsey bought all of the coal underlying the land of Dr. M. F. Compton, turning the same over to the Mound Coal Co., which operates the mine on First St. The transaction gives the mining company an unrestricted right-of-way from the railroad to the Ohio River.

Scranton, Penn.—A sliding-scale bonus of $1050 was recently awarded by the Archbald Coal Co. to the miners who worked for this firm in March, 1912. The matter was finally adjusted by district board members, Stephen Reap and Harry Kerins, and the first half of the bonus will be paid immediately, and the balance during the latter half of February.

Bristol, Conn.—The New Departure Mfg. Co. will shortly occupy its large and handsome administration building which has been in the course of erection for the past 12 months. De Witt Page, who has been identified with the company for some time, has been appointed general manager, and Chas. B. Treadway, Treas., becomes chairman of the Board of Directors.

Detroit, Mich.—The 1914 sale convention of the American Blower Co. was held in Detroit on Jan. 28 to 30, and was attended by about 50 of the company's sales and engineering representatives. Somewhat contrary to expectation, pessimism had no place whatever in any part of the convention, and the feeling was general that more and better business would be handled in 1914 than was booked during the previous year.

Harrisburg, Penn.—The State Department of Mines reports that 1141 mine workers were killed in and about the mines of Pennsylvania last year. Of these, 615 met death in the anthracite region, and 526 in the bituminous district. The number of employees in the first named field is given as 180,000, and in the latter 185,000. The bituminous miners produced 168,000,000 tons of coal against 90,000,000 produced in the anthracite field during the same period.

Washington, D. C.—Discrimination by the Pennsylvania R.R. on rates of bituminous coal in favor of the Keystone Coal & Coke Co. and the Jamison Coal & Coke Co., both of the Greensburg dsitrict as against the Pittsburgh Coal Co. was recently charged by the traffic manager of the latter company before the Interstate Commerce Commission, while testifying in the hearing on the proposed 5 per cent. advance in rate for the railroads in the Eastern classification territory.

Denver, Colo.—Holding that the Union Pacific, Chicago, Burlington & Quincy, and Colorado & Southern railroads are charging an exorbitant rate for carrying coal from the northern Colorado fields to Denver. Judge Terry recently upheld the findings of the State Railway Commission, and ordered a reduction amounting to approximately 30 per cent. Unless Judge Terry's ruling is reversed by the Supreme Court to which the railroads will go on a writ of error the rate fixed by the commission of 55c., 50c. and 45c. per ton for lump, run of mine and slack coal will prevail as against the present rates of 80c., 70c. and 60c. a ton, respectively.

Uniontown, Penn.—Figures from the office of the commissioners of Greene County show that J. V. Thompson, of Uniontown, is in all probability the most expensive individual holder of coal in the United States. Greene County has 18 townships, and in 17 of these, Thompson owns coal. His total holdings aggregate 120,000 acres. If an acre of coal after being mined and placed on the market is reckoned as worth $10,000, this valuation of the coal held by Thompson would give a potential value of $1,200,000,000. None of the coal held, however, has been developed, Thompson being a speculator in virgin coal and not interested in its mining or sale.

Coal Trade Reviews

General Review

Colder weather creates some activity in anthracite but the domestic sizes continue under heavy pressure; steam grades still short. Demurrage and embargoes the rule in bituminous. Conservative interests accumulating surpluses against a suspension Apr. 1.

The recent colder weather acted as a temporary stimulant to the anthracite trade, but the movement was so prompt that the situation was easily met before it had an opportunity to affect the wholesale end. The fact that the independent operators are finding it necessary to curtail their production is significant evidence of the trend of conditions in this branch of the industry. There is a heavy loading of lake vessels in the Buffalo harbors. Consumers in all departments report a substantial decrease in consumption and there are many who predict that even the large companies will be forced to make concessions on the winter circular before the customary time, Apr. 1. Operations are so heavily restricted, as a result of the poor demand for the domestic grades, that the steam sizes are becoming steadily shorter and commanding larger premiums. Anthracite shipments for January were the lowest for that month since 1905.

Nominal prices are being relatively well maintained in the Eastern bituminous market but the large amount of consignment coal on demurrage is resulting in many sales at ridiculously low prices. There is practically no demand for spot coal and while a few contracts are being closed for the new year, embodying clauses protecting the consumer against a further decline, most agents are not actively seeking business; in view of the adverse conditions prevailing it is difficult to negotiate on a profitable basis, and sellers hesitate to weaken their position by attempting to force the market.

The possibility of a protracted suspension, Apr. 1, is creating confusion and a great diversity of opinion prevails as to the result. The larger conservative Eastern buyers are showing a disposition to stock up heavily in spite of the miners' tentative offer to continue at work pending a settlement. In other districts, however, the buyers are already so heavily stocked in excess of current requirements that they will not consider further offers.

Considerable coal is reported in the Pittsburgh district accumulating demurrage and operations are restricted to probably not more than 50% capacity. Many orders in Ohio placed for February delivery have been canceled, and the market is in bad shape. Hampton Roads reports continued light demand for spot coal, but a rather increased movement on contracts has materially reduced accumulations. Hopes of any real winter weather in the South have been abandoned and the market is quiet with shipments below the average for this period of the year; companies will enter the summer trade with heavier stocks than ever before.

The first seasonable weather of the winter has occurred in the Middle Western market and created a more active situation there. This has checked the tendency to cut prices and mine operations are much better, while the improvement in other lines of industry is also helping the situation. Some buying in anticipation of the impending labor troubles is also noted.

EASTERN MARKET

BOSTON

Active canvass for contracts by Hampton Roads agencies. No significant concessions in price thus far. No demand for spot coal. Water freights rather unfavorable to Pennsylvania coals and little doing. Anthracite extremely quiet.

Bituminous—The Pocahontas and New River shippers are actively canvassing for contract business. A few large orders have been entered through the customary channels and with the usual clause protecting the buyer against a decline in price and also including a provision with regard to the possible advance in tolls. Such arrangements are, of course, only options and have no direct bearing on the future of the market, but this is the only form in which buyers will consider making contracts at least for the present; $2.85 is still being maintained as the base price and what concessions are heard are confined to the smaller agencies who have to deal with accumulations at the Hampton Roads piers. Shipments from that quarter are still light for the season.

For spot coal there is practically no demand whatever in this territory. A large cargo of Southern coal was delayed here, discharging for more than a week recently, awaiting orders for distribution inland; that sort of procedure always has a depressing effect on what market there is. Stocks are large in every direction and nothing short of extravagant inducements will bring forth any material amount of business.

The high range of water freights maintained out of Philadelphia operates against any call for the Pennsylvania grades along the coast and what small orders offer are likely to find their way to the coals from Hampton Roads. Practically all the Pennsylvania districts, as well as Georges Creek, are under heavy curtailment, with no significant change in sight.

Anthracite—There is only a scattering demand for sizes, but some improvement is hoped for from the colder weather. Stocks to the Eastward are running down and there is reason for predicting a good demand as soon as April prices are in force. The independents are little heard from in this territory, and practically all the coal that is sold is on the current company circular. Moderate supplies continue to come forward to storage depots.

From all quarters it appears that the consumption of stove size is still increasing, while egg is as steadily growing less in demand. It will be interesting to see how this situation works out the coming season.

Wholesale quotations on bituminous are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.95@1.50	$1.25@1.55	$1.67@1.77	
Philadelphia*	2.20@2.75	2.50@2.80	2.92@3.02	
New York*	2.50@3.00	2.80@3.10	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.80@2.85
Boston†				3.58@3.65
Providence†				3.58@3.68

*F.o.b. †On cars.

NEW YORK

Many embargoes are being declared on soft coal. Few negotiations on contracts for the new year. Much demurrage coal and some low prices being heard. Heavy pressure on domestic grades of anthracite with steam sizes in strong demand.

Bituminous—Further recessions continue to mark the local soft-coal trade. There are large surpluses of coal at South Amboy and embargoes have been declared against certain consignees; these are having a beneficial effect upon the situation, however, by curtailing the shipment of market tonnages into a trade already oversupplied with coal of all kinds. On Feb. 9 the Philadelphia & Reading Ry. announced embargoes on all shipments of bituminous coal to consignees at Port Richmond, Philadelphia and Port Reading, N. J.

The movement on contracts continues to be the mainstay of the market, particularly for those operators who are not attempting to overload their customers. However, even the contract movement is getting steadily weaker, although there are a few consumers who are taking some extra in anticipation of a suspension Apr. 1. On contracts for the new year, the conservative selling agencies are not attempting to push for business, believing that their position would be materially weakened, should they do so in the face of the adverse conditions now prevailing. Consumers, on the other hand, are holding off, awaiting developments. Operations are already heavily restricted, and if no suspension occurs, the outlook for the summer business is decidedly pessimistic.

Because of the large amount of demurrage coal being negotiated, abnormally low prices are heard, as much as

45c., f.o.b. mines, being on gas coal. This condition is due to operators attempting to force the market, being ready to make sacrifices in order to hold their mine organizations together. Disregarding such sales of demurrage coal, we quote the nominal New York market off 5 to 10c. per ton from last week as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.60@2.70; good grades of Pennsylvania, $2.60@2.70; best Miller Pennsylvania, $3.10@3.15; George's Creek, $3.15@3.25.

Anthracite—Although the recent cold weather has had a momentary stimulating effect upon the situation, the market continues discouragingly flat and devoid of interest. Operations in the mining regions are being restricted in an unprecedented manner for this period of the year, the curtailment being shared in by the large companies and individuals alike. A conservative estimate places the operations at not to exceed 60% capacity, as a maximum.

The pressure is concentrated entirely upon the domestic grades, as is to be expected. The difficulty in moving these has resulted in the curtailment of mining and has also placed the producers in an embarrassing position as regards the steam grades. Contracts were entered into for tonnages of these latter, gaged upon full-time operations; obviously, with mining restricted as it is, the expected output of the small sizes is not being realized, with the result that producers are unable to meet their obligations on these grades. It is not surprising, therefore, that premiums are being freely offered for all kinds of small coal, while the reverse obtains in the prepared grades, all of which are a drug on the market.

We quote the New York market on the following basis:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.00	$4.50@4.75	$5.05	$4.45@4.70
Egg	5.25	5.00@5.25	5.30	4.65@5.20
Stove	5.25	5.00@5.25	5.30	5.00@5.20
Chestnut	5.50	5.35@5.50	5.55	5.35@5.45
Pea	3.50	3.40@3.50	3.50	3.15@3.45
Buckwheat	2.75	2.75@2.85	2.70@3.45	2.25@2.80
Rice	2.25	2.25@2.35	1.95@2.20	1.85@2.30
Barley	1.75	1.75@1.80	1.70	1.55@1.70

PHILADELPHIA

Anthracite situation receives impetus due to colder weather. Steam sizes in active demand, but domestic market well supplied. Bituminous unchanged, but still reflecting low prices and limited demand.

Weather conditions have been more favorable during the past week for the anthracite coal trade, and while the wholesale market has not felt the impetus as yet, the retail end has profited more or less. While both classes of the trade seem to feel more optimistic, the general idea seems to prevail that one week of winter will not bring about any lasting results; the householders, recognizing that winter weather in this vicinity is not likely to last much longer, will economize to the greatest extent in the purchase of coal, and it will require at least four to six weeks of a continuous spell to dispose of the large stocks which most of the dealers are carrying. Many of them are doing considerable shopping in the face of the present market conditions, and are doubtless securing bargains on almost all of the prepared sizes.

The fact that even the individual operators have been curtailing operations at their mines does not speak well for the market, and judging from reports, they are having difficulty in disposing of their output at that. The large companies are still adhering to circular prices. It is understood with the curtailed mining, it has been impossible to fill contract obligations on the steam grades, and large inroads are being made into stocks; buckwheat is in particularly short supply. Broken coal seems to be about the only senior size that is short of the market, the contracts in some cases being far behind actual requirements; operators claim they cannot mine coal to supply a market for only certain sizes as they have to dispose of all.

The tidewater market from this city has fallen flat. Orders are few and far between, and it is understood that many of the barges of the transportation companies are being tied up on account of the lack of business. Everybody seems to be postponing taking on additional coal as long as possible, and the New England market is said to be well filled.

Depressing influences still continue to characterize the bituminous market in the shape of poor prices, and limited demand. Inferior coals are being offered as low as 80@90c. at the mines, and they are not particularly easy to dispose of at that. Better grades of coal are ruling at 35@40c. higher.

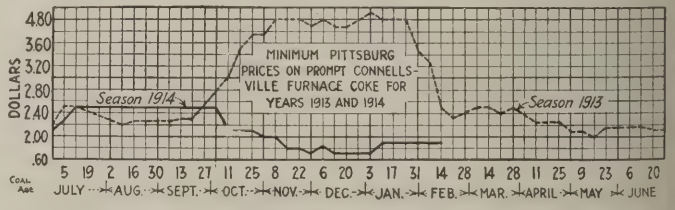
BALTIMORE

Cold snap has proven highly beneficial to the anthracite trade. Bituminous business still rather flat, with prices poor. Rumors of anticipated labor trouble causing interest. Heavy shipments over the piers.

A welcome drop in temperature has already had a distinct influence for good on the anthracite trade. The hard-coal business here has been flat for several weeks, but there is now a briskness to orders that is most encouraging. The movement from mines to tide proved prompt, however, and the situation was easily met as regards the domestic grades. There has been a growing demand for this latter class of coal here despite the fact that dealers have several times advanced the price.

While the soft-coal situation is for the moment uneventful there are rumors of labor troubles the coming April, In the face of the recent poor demand for soft coal and the low schedule of prices an unsettled labor situation might not prove entirely unwelcome. A little more activity was shown in West Virginia gas coals the past week, this fuel having recently been the most unsatisfactory feature of a poor market generally. Three-quarter gas is still selling to the trade at the mines around 80c. Steam coals of West Virginia are averaging around 90 and 95c. with liberal offerings on prompt delivery. Pennsylvania lower grades are running from 90c. to $1 while the best grades still hang at from $1.20 to $1.30.

The trans-shipment business here is quite satisfactory, at least to some handlers, as considerable business is being done both coastwise and to foreign ports. The vessel charter situation still remains easy in spite of a number of closings. There is considerable range in charters, ,African, European. South American and Central American loadings being noted since the first of the year, during which a total of about 100,000 tons has been exported up to the start of the present week.



CENTRAL STATES

PITTSBURGH, PENN.

No prospect of wage scale agreement at Philadelphia conference, begun this week, and little possibility of mining suspension being avoided. Mine operations lighter, at less than 50% of capacity. Connellsville coke market quiet, but with better undertone. Shipments increased.

Bituminous—It is out of the question that this week's scale conference at Philadelphia should reach an agreement, but it is barely possible that arrangements will be made whereby there will be no suspension of mining in case agreement on the scale is not reached by Apr. 1. The balance of probabilities is clearly that there will be a suspension, and one of considerable duration. Some of the demands of the men, as formulated at the Indianapolis convention, are regarded by operators as impossible.

The coal market continues flat, owing to light domestic, industrial and railway demand. A sharp cold snap reached the district Sunday and domestic demand may prove better for a few days. There is considerable coal at distributing points without instructions, and demurrage is accumulating, resulting, it is claimed, in the railroads picking up some coal at bargain prices which will be held against the possible suspension of mining. Mining operations are somewhat reduced, and probably average less than 50% capacity. A number of mines are entirely idle, while many others are operating only from two to four days a week. Prices are rather badly cut on free coal, and even in some instances on slack, the regular circular prices remaining as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The market has been quiet as to actual transactions, but is showing an improved undertone. It is believed that low-priced sellers are fairly well filled for as large a tonnage as they would care to take at under the $2 asking price of the majority of operators, while the somewhat significant incident has occurred that the Producers' Coke Co. has withdrawn all prices for shipment after Apr. 1. The move is not necessarily of significance from the fact that any inquiry likely to develop is only for early de-

livery, and the companies represented in this selling agency are not likely to miss any business by staying out of the market for the later delivery; at the same time they are placing themselves in position to profit by any material improvement that may occur in the iron situation and any sharp demand that might arise for raw coal through a suspension of mining in the union districts. It is claimed that under normal coal market conditions there is about as much profit in coal as in coke at less than $2. The coke market continues to be quotable as follows: Prompt furnace, $1.90; contract furnace, $1.90@2; prompt foundry, $2.40@2.60; contract foundry, $2.40@2.60, per ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ending Jan. 31 at 301,055 tons, an increase of 10,000 tons, and shipments at 298,541 tons, an increase of 7955 tons.

BUFFALO, N. Y.

Capricious weather and too much coal weakens all prices. No strong market till steady low temperatures set in. Miners' actions closely watched. Loading vessels.

Bituminous—The market has strengthened a trifle, but the general erratic weather has kept prices unsteady. It is getting so late now that the trade is not looking for much of a market this winter unless it is later found that there is not likely to be coal enough to last through a reasonably long mining suspension. While it was announced that the miners would continue work after Apr. 1, pending a fixing of mining prices, the operators say the mines will be closed at the end of March and remain so till there is some profit in the business. This is the feeling all through the mining districts. Some of the operators say they expect to be shut down till sometime into May.

The miners are complaining that they do not get as much work as they need, mines often running only about half time, due to the condition of the market. Still there are many members of the trade who are decidedly cheerful; iron moves more freely and some are saying that by Mar. 20 there will be a good volume of all sorts of business. There is much activity in Buffalo harbor. The loading of anthracite for lake shipment in the spring has been resumed and the steamers are mostly putting on their fuel against shortage next April. As they are taking about 500 tons each the aggregate is large.

Bituminous prices are slightly stronger on the basis of $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run and $2.10 for slack. The price of Allegheny Valley is about 25c. lower for sizes, with slack about on a par with Pittsburgh.

Coke—There is no particular stir in coke. The amount going into consumption is larger than it was a month ago, but that appears to be only just enough to keep it from going lower. Prices are based on $4.50 for best 72-hr. Connellsville foundry.

Anthracite—The trade has not improved materially. Mines are running slow, and there is much complaint of stocks at practically all points. Consumers are reporting a large reduction in the amount consumed and indications are that not only the independents, but larger interests also will sell at April prices sometime before these go into effect. The retail trade has done less business here so far this winter than during any similar time on record.

COLUMBUS, OHIO

Ohio trade fast approaching demoralization. Circular prices being cut, and there is considerable tonnage on track. Not much stocking against a shortage in case of a suspension.

With low prices prevailing for all grades of coal and with no disposition on the part of steam users to stock up the coal trade is weak and quiet. Operations are at a low ebb and sales managers are able to place scarcely any tonnage. On the whole the market is in bad shape.

Production has become still smaller during the week as many mines have been closed down entirely and others are being worked with only a small force. Several operators who have been shipping on consignment have stopped which has cut into production still further. In the Hocking Valley the output is estimated from 35 to 40% of the average and the Pomeroy Bend district produced about the same percentage. In the domestic fields the output was about 25% of normal. In eastern Ohio the reports show that about 40% of the average was produced during the week.

Domestic business is slow as dealers are not inclined to stock up; their bins are full and the weather has been such that they cannot move it. Many of the orders placed by retailers for delivery early in February have been canceled. Domestic lump and ¾-in. are a drug on the market and spot coal can be bought for almost any price. There is some little demand for the fancy grades of rescreened West Virginia and Pocahontas.

Steam business is steadier but there is unusual quietness. Factories are taking about their usual requisitions, which means they are gradually accumulating stocks as their daily needs are not equal to receipts. Only a few railroads which do not touch the coal fields are stocking up any.

Most of the operators in the Ohio fields believe nothing can prevent a suspension after the expiration of the present wage agreement. The statement comes from West Virginia that there will be a suspension in that state also, in order to allow the tonnage on track to be cleaned up. Prospects for an active lake trade next season are not very promising as there is still a large amount of coal on the docks at the upper lake ports.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.40 @ 1.35		$1.50 @ 1.45	$1.40 @ 1.35
3-4 inch	1.25 @ 1.20	$1.20 @ 1.15	1.35 @ 1.30	1.30 @ 1.25
Nut	1.25 @ 1.20		1.30 @ 1.25	1.20 @ 1.15
Mine-run	1.10 @ 1.05	1.10 @ 1.05	1.15 @ 1.10	1.10 @ 1.05
Nut, pea and slack	0.80 @ 0.75		0.80 @ 0.75	0.80 @ 0.75
Coarse slack	0.70 @ 0.65	0.95 @ 0.90	0.70 @ 0.65	0.70 @ 0.65

CLEVELAND, OHIO

A slight improvement in the demand for slack. Close of last week developed temperatures approaching zero which gave the coal market a boost. Some larger manufacturers taking contract coal and the market has the appearance of cleaning up.

The colder weather that threatened northern Ohio the first of the month failed to materialize and last week the weather was almost spring like until Saturday, when a real cold wave swept the northern part of the state.

In spite of the warm weather the American Steel & Wire Co. began taking coal from its shippers who had been shut off for two weeks. Many factories have been embargoed because they cannot unload the cars. The American Steel & Wire Co. has a 30 days' supply on hand and many other plants have from two to three weeks' stock stored away; the Lake Shore R.R. has a month's supply of coal docked and other roads have stocked some, but more docking will be done before Apr. 1.

The hard-coal market has been so slow car service is being paid on coal on track. Until the cold wave struck the city, both Cleveland and its surrounding market offered little immediate prospect of absorbing the small amount of anthracite on hand.

The retail trade has had a fair business under the adverse conditions. None of the larger firms had all of their equipment working though, considering the weather, they did very well.

The wholesale market was well stocked with lump coal, especially from the No. 8 district. The larger demand for slack has left three-quarter, and inch and a quarter sizes to be disposed of on an overstocked market. This resulted in a continuation of the low prices on the larger coals, while slack was sold at an advance of 5c. Pocahontas is as low as it has been for several months. The fall prices were from 50 to 60c. above those that are prevailing today.

The Massillon district is not sending its product into the flat market. Many of the mines are shut down or working only a small part of the time. Operators in this district have a single price below which they cannot go without losing money and they have maintained this circular so far. Prices ranged a little higher last Saturday than during the middle of the week. Although the amount of coal that comes into Cleveland on Sunday and Monday tends to take the edge off the market as it closed the previous week, a continuation of the cold weather will probably bring a decided betterment during the next few days.

Sales of spot coal were made at the following car prices:

	No. 8	Middle District	Pocahontas
Lump, 1¼-in.	$2.00@2.10	$1.90@2.20	$3.25
Lump, ¾-in.	1.90@2.00	1.85@1.90	
Mine-run	1.85	1.75@1.80	2.75
Egg			3.25
Nut	2.10		
Slack	1.80@1.85	1.70	

DETROIT

Demurrage coal disappearing and a better tone evident in most quarters. Embargoes on local roads. Buyers becoming anxious.

With all the railroads leading into Detroit embargoed against fuel, and the recent sudden cold snap operators and jobbers are beginning to be optomistic. The steam business has shown a specially marked improvement in the last few days.

Buyers are anxious to be taken care of, and the several hundred cars of demurrage coal that have been on local tracks for the past three weeks are melting away quite rapidly as the demand increases. Should the cold weather continue, and the railroads delay in raising the embargo, it is possible that Detroit may experience a slight coal famine

within the next 10 or 15 days; should the weather moderate to any great extent, and the embargo raised, the local market will again be flooded with steam fuel from West Virginia, Ohio and Indiana, in such large quantities that it will be difficult to obtain even 50c. a ton for mine-run.

Anthracite—The large supplies of hard coal, are now being disposed of quite rapidly. The demand has increased materially and for spot cars, 25c. above circular is being asked.

HAMPTON ROADS

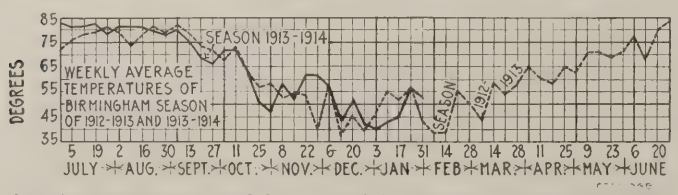
Conditions at Hampton Roads improving. Total dumpings for January. Accumulation of coal on railway yards somewhat reduced.

The situation at Hampton Roads is gradually improving and although there is little demand for spot coal the movement on contract during the week has considerably reduced the accumulation of cars on the various railway terminals. The largest shipments coastwise, as usual, have gone to the New England market with a fair number of cargoes moving foreign. These latter went to Bermuda, Canal Zone, Barbadoes, Dakar, Havana, Santiago, Rio, Kingston, St. Thomas, Valparaiso and Genoa. Perhaps the largest shipment of the week was that moving to Genoa this cargo amounting to about 10,400 tons. Approximately 2600 tons moved by schooner from Hampton Roads to Ponce, Porto Rico. The commander of the French oil supply ship "Garonne" asked for bids for supplying French government vessels with bunker coal at Hampton Roads. It is understood the price made was the regular foreign bunker rate plus cost of barging and stevedoring for such vessels as could not load at piers and the regular foreign bunker price for such as bunkered at piers. This contract is to cover 1914.

Dumpings over Hampton Roads piers for January amounted to 984,301 tons. Of this quantity the Norfolk & Western Ry. at Lamberts Point dumped 508,212 tons. the Chesapeake & Ohio Ry. from Newport News 247,219 tons and the Virginian Ry. from Sewalls Point 230,870 tons. From these figures it will be seen that the Norfolk & Western dumped considerably more than the other roads combined.

LOUISVILLE, KY.

Colder weather stimulates retail trade, but arrived too late to help the wholesale business. Prices on a midsummer basis. Steam market improving.



While the belated cold wave has finally arrived, the effect so far has not been noticeable in the wholesale end of the trade although the retailers have profited by the resulting increase in the demand. As pointed out heretofore, it will take a prolonged period of low temperatures to reduce retailers' stock to a point where they will have to place new orders, and the lateness of the season makes it improbable that the present cold snap can last long. Small orders are the rule with domestic consumers, and there is little doubt but what hand-to-mouth buying will continue. The total volume of business will be much smaller than it would have been had the present severe weather occurred a month or more ago.

SOUTHERN AND MIDDLE-WESTERN

BIRMINGHAM, ALA.

Little improvement in coal and coke. Market quiet and shipments below the average for this season of the year. Heavy tonnage of pig iron booked and prices advanced to $11 f.o.b., Birmingham, for 2 Foundry. Car situation satisfactory.

This week has shown little improvement in either steam or domestic coal. Warm summer-like weather has prevailed

for the past week, and lump coal is in small demand, though colder weather is predicted for the next ten days, which may bring about an improvement; prices are from 25 to 50c. per ton less than the February circular. Steam coal is also feeling the effects of the quiet market, but unlike the lump, the prices are holding up well under the circumstances. Furnace and foundry coke are quiet, sales in small tonnages only being made. Blacksmith coal is slightly better than last week, prices being from $2 to $2.25 f.o.b. mines.

A heavy tonnage of pig iron was again booked by the furnace companies, which are now holding for $11 f.o.b. Birmingham for 2 Foundry, some sales being made at $11.50. The iron market is in a better condition than it has been for several months. The car supply is quite adequate for the demands at this time.

NEW ORLEANS

Local sales much below last year. Larger business anticipated this summer due to higher prices of fuel oil.

All hope of protracted cold weather has been abandoned by retail dealers here. Sales for domestic purposes are 45% lighter this year than normal. As a result the influx of coal from the mines has been suspended as practically every company will enter the summer with larger stocks than ever before has been the case. It is expected, demand this summer will be larger, due to the number of steam plants that are returning to the use of coal because of increasing cost of petroleum.

INDIANAPOLIS

January was an unusually poor month but February weather is putting the coal trade at its best. Consumption of domestic grades has a boom and factory needs are gradually increasing. Mines working on slightly better time and prices hold firm.

February is displaying the most seasonable weather Indiana has had since summer ended. January was one of the mildest winter months on record for this state and the coal dealers, who had counted on making up for the slowness of fall trade were sorely disappointed. February came in with snow and sleet that not only increased the consumption of coal but caused much damage to wire communication and delayed transportation. The sun came out the third day but later a cold wave followed that carried the temperature down to about zero and retail coal dealers all over the state quickly fell away behind orders.

This was what was needed to stiffen the coal market, as there were reports of a shading of prices, which seemed to threaten to become general. As it is, no change is made from the retail schedule adopted at the beginning of the season. Mine prices are firmer and operations better, due to the cold spell and some improvement in the industrial situation. There is a general preparation for greater activity in this line and the working forces are being slowly but steadily enlarged, though in some cases, hundreds of men are taken back at once.

CHICAGO

Market continues soft. Producers eager to accept business at almost any price. Smokeless mine-run selling at $1@1.05, while lump and egg are being disposed of at $1.50. The top price for Carterville lump, egg and No. 1 washed is $1.60. Coke prices remain nominal.

"Continued soft" is the essence of comment among Chicago coal dealers, so far as market conditions are concerned. While zero weather has visited the territory this winter, it has not remained long enough to have any appreciable affect upon business. Producers and wholesalers will accept almost any price that is offered. Unusual weakness has been shown in the smokeless coal market; sales of smokeless mine-run at $1 and $1.05 have been frequent and lump and egg are being sold as low as $1.50.

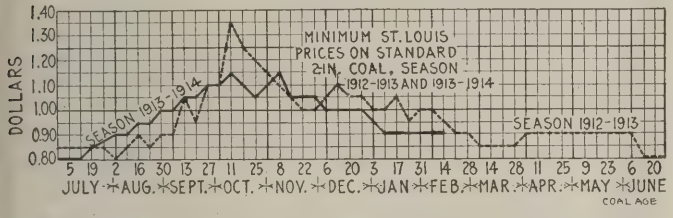
The splint coal market, nominally, is $1.50 on shipments direct from the mines, but a large amount of large-sized splint lump on demurrage is being sold as low as $1 a ton. As a result of a general scramble for business, Franklin County operators are selling lump and egg at from $1.40@1.60, the mines. Quotations for mine-run range between $1.15 and $1.20.

Carterville operators are seeking business at almost any price that will attract trade. The top price for lump, egg and No. 1 washed is $1.60, and a less figure is being accepted for coal on demurrage. Springfield operators have been compelled to shade prices as a result of sharp competition.

Coke prices are practically nominal. Sales are made with difficulty as the current demand is light. There has been a slight upward tendency in the steam trade, but conditions are far from satisfactory.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic lump	$2.07@2.17	$2.45@2.65	$2.12@2.27	
Steam lump	1.87		1.97	
Egg		2.45@2.65		$3.90@4.30
Mine-run	1.82	2.20@2.25	1.87	3.20@3.45
Screenings	1.37@1.42	1.70@1.80	1.37@1.42	



Coke—Connellsville, $5.25@5.50; Wise County, $5@5.25; byproduct, egg, stove and nut, $4.90; gas house, $4.65.

ST. LOUIS

Seasonable weather has caused an advance in prices, which will likely continue if cold wave holds out. Steam sizes still weak and slow movement of anthracite, coke and smokeless. Some storage supply being bought in anticipation of a suspension.

The first real touch of winter, as far as cold weather was concerned, arrived last Saturday, and it had a decidedly good effect on the market, beginning Monday. Prices advanced slightly on nearly all grades, and if the weather continues cold the latter part of the week will see a general advance that will likely continue.

There has been some buying of storage coal in the last few days, which has brought about healthier conditions in certain sizes, but on the whole there has been no material change. The washed-coal market is in a deplorable condition, with the exception of Nos. 4 and 5, which seem to be in fairly good demand.

The middle of last week Franklin County went down to $1.20 and Carterville to $1.05 on the domestic sizes. Standard 2-in. lump was sold freely at 80c. On the other hand, there was no advance in the screenings price. Carterville being held at about 60 to 65c. and Standard at 40 to 45c. A few plants in the south are storing coal, but there seems to be no inclination on the part of Northern steam users or railroads to acquire any surplus.

Anthracite, smokeless and coke are coming in with no demand, and going at any price the market will bring.

Prices continue unchanged from last week.

KANSAS CITY, MO.

Colder weather and an increased demand for fuel. Mine operations increased. Failure of gas supply has an important bearing on the market.

The market has stiffened to an appreciable degree, though no actual advance in quotations has yet been made. A continuance of present conditions, however, will result in this action. The situation is further improved in Kansas City and other cities in the Southwest, through the partial failure of the gas supply. The reserve accumulated during the mild weather has been consumed and the obvious and only remedy is to utilize coal.

PORTLAND, ORE.

Mild weather continues and little business being negotiated. Some interest over opening of Alaskan coal lands.

The Pacific Northwest is still enjoying a mild open winter and as a consequence the demand for coal for domestic purposes is not heavy.

The Portland Chamber of Commerce is investigating the possibility of cheaper coal on the Pacific Coast if the proposed government railroad is built into the interior of Alaska, and it is pointed out that with less expensive fuel the demand would be much larger than now as coal would displace other fuels and also stimulate industrial activity now hampered by the prohibitive fuel prices.

PRODUCTION AND TRANSPORTATION STATISTICS

IMPORTS AND EXPORTS

The following is a comparative statement of imports and exports in the United States for November, 1912-13, and for the 11 months ending November, 1911-12-13, in long tons:

	11 Months			November	
Imports from:	1911	1912	1913	1912	1913
United Jingdom.	8,290	6,294	5,329	1,430	70
Canada	873,265	1,204,416	979,980	124,714	82,491
Japan	11,373	25,663	99,437	4,945	10,322
Australia and Tasmania	207,945	151,928	160,754	11,426	19,176
Other countries	355	2,202	3,296	97	.....
Total	1,101,228	1,480,503	1,248,796	142,612	112,059
Exports:					
Anthracite	2,312,755	3,404,958	3,927,995	372,267	329,652
Bituminous,					
Canada	9,917,740	9,838,701	12,749,300	930,733	1,086,831
Panama	451,743	423,327	452,551	27,100	32,871
Mexico	449,671	269,007	439,427	12,350	22,165
Cuba	941,504	1,033,220	1,200,958	89,958	89,385
West Indies	511,608	602,406	548,454	38,458	24,194
Argentina	.....	.....	70,048	.....	8,171

Uruguay	.....	.....	5,163	.....	.....
Other countries	608,076	1,383,092	1,140,217	55,378	39,944
Total	12,880,342	13,549,753	16,856,781	1,153,977	1,313,125
Bunker coal	6,118,494	6,766,443	7,093,271	610,153	610,251

ANTHRACITE SHIPMENTS

As anticipated, the hard-coal shipments for January experienced a sharp decline, amounting to only 5,175,732 tons as compared with 5,663,618 tons in December, and 6,336,419 tons in January of last year. Shipments were the lowest for this month since 1905, when 4,408,575 tons were handled. The nearest approach to this low record since that time was in 1909 when 5,183,345 tons were shipped.

It is interesting to note that the Reading company has again resumed the leadership as the largest mover of hard coal in the country. For the first time in the history of the anthracite statistics the Lehigh Valley outstripped the Reading in shipments last December by some 4000 tons, but Reading again assumes the lead in January by a comfortable margin of fully 20 per cent.

A rather encouraging feature of the current situation is the comparatively light stocks reported at tidewater. On Jan. 31 the stocks were 591,094 tons as compared with 602,328 tons Dec. 1. As compared with Jan. 31, 1913, stocks are considerably larger, supplies on that date being 375,566 tons, and on Jan. 31, 1912, 521,283 tons.

January shipments were as follows:

	Domestic		Steam		Total	
	1914	1913	1914	1913	1914	1913
Phila. & Reading	888,210	1,118,635	126,916	138,497	1,015,126	1,257,132
Lehigh Valley	753,819	1,062,367	56,769	112,784	810,588	1,175,151
Cent. R. R. N. J.	604,368	691,764	100,123	121,603	704,491	813,367
Del. Lack. & West.	525,481	758,576	93,457	163,523	618,938	922,099
Del. & Hudson	509,582	563,369	77,311	89,808	586,893	653,177
Pennsylvania	458,356	505,873	77,762	70,679	536,118	576,552
Erie	602,331	596,165	103,972	121,070	706,303	717,235
Ont. & Western	179,544	202,916	17,731	18,790	197,275	221,706
Total	4,521,691	5,499,665	654,041	836,754	5,175,732	6,338,419

SOUTHWESTERN TONNAGE

The following is a comparative statement of the Southwestern tonnage for September and the first nine months of the years 1912 and 1913:

State	September		Nine Months	
	1912	1913	1912	1913
Missouri	242,871	250,763	2,122,744	2,049,969
Kansas	424,329	474,237	3,628,190	4,060,330
Arkansas	169,325	201,782	1,374,474	1,406,787
Oklahoma	249,604	297,213	2,064,561	2,523,135
Totals	1,086,129	1,223,995	9,189,969	10,040,221

This statement only covers the tonnage of members of the association, which is estimated to be at least 95% of the entire tonnage produced in the four states.

CHESAPEAKE & OHIO R.R.

The following is a statement of the coal and coke tonnage over the C. & O. R.R. for December, 1912 and 1913:

	Coal			Coal and Coke		
	December		Nov.	December		Nov.
	1912	1913	1913	1912	1913	1913
New River	463,230	469,490	502,230	485,550	486,230	518,520
Kanawha	708,980	958,740	787,400	712,520	961,020	880,040
Kentucky	153,180	145,810	155,970	155,610	157,060	163,920
Total	1,325,390	1,574,040	1,535,600	1,353,680	1,604,310	1,562,480

FOREIGN MARKETS

GREAT BRITAIN

Jan. 30—Supplies of large coals of most Admiralty qualities are abundant for early shipment, and the market is irregular in tone. Monmouthshire large coals are steadily held for prompt. Quotations are approximately as follows:

Best Welsh steam	$4.50	Best Monmouthshires	$4.17
Best seconds	4.38	Seconds	4.05
Seconds	4.26	Best Cardiff smalls	2.70
Best dry coals	4.38	Seconds	2.52

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are net f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days.

Financial Department

The Coal and Coke Railway Company

President H. G. Davis, of this company, reports, in part, for year ending June 30, 1913, as follows:

Railway Earnings—While the gross revenues increased 11.6%, or $129,911, the operating expenses increased 18.6%, or $126,801. The expenses were increased chiefly by the higher wages paid to engineers, firemen and trackmen and the cost of repairs, amounting to some $20,000, necessitated by the floods of last summer. The net earnings from railway operations, after deducting taxes of $42,000 and ground rents of $2254, were $396,829, a slight increase over 1911-12.

Coal Department—There was a gratifying improvement in the earnings of the coal department. In the previous fiscal year the trade was greatly depressed, prices often being below the cost of production, and as a result the coal operations, after paying the rental, showed a slight loss. In the late fiscal year trade conditions were much improved, the market being good, with prices firm for both coal and coke. In consequence thereof, there was a clear profit, after paying the yearly rental, of $101,845.

Total Results—The profit of the coal department, together with the income of $27,481 from other sources, added to the profit from railway operations, gives the result of $526,155 applicable to fixed charges, and leaves, after payment of the same, a net surplus of $216,416, being an increase of $154,662 over 1911-12.

Improvements, Etc.—There was expended for betterments, heavier rails, side tracks, ballasting, etc., $43,666; betterments to equipment, $12,043, and in additions to coalplants, $19,628. These three items, amounting to $75,338, deducted from the surplus of $216,416, leaves a clear income of $141,078, which was used in paying equipment warrants, debts, etc.

Traffic Earnings—The coal and coke tonnage has continued its steady growth and the increase in freight earnings therefrom was $37,447. In three years the revenue from this source has increased 76%, and it is expected that it will soon reach the earnings from miscellaneous freights. As coal and coke take the lowest freight rates, they require a correspondingly larger volume of traffic to equal the miscellaneous freights in earning capacity. In the shipment of coal and coke produced on its line, the road last year exceeded for the first time a million tons, the exact amount being 1,016,690, an increase over the year before of about 20%, and nearly double the tonnage of 1910.

Coal Lands—The railroad owns about 100,000 acres of coal lands and coal-mining rights, all carefully selected within actual coal areas along its route in Randolph, Barbour, Upshur, Lewis, Gilmer and Braxton Counties, W. Va. In practically all of these coal lands the measures are above water level and the coal can be easily and economically mined by drift. Among the seams are the Pittsburgh, Sewickley, Masontown, Mahoning, Upper Freeport, Kittanning and New River seams. In addition to their steam-producing qualities, most of them are also excellent coking coals.

The railway company has also what is virtually a perpetual lease of all the properties of the Davis Colliery Co., and the latter is conducted practically as the coal department of the railway. It operates and markets the products not only from the mines on the coal lands of the railway, but on its own as well, and the profit from both sources above the rental accrues to the railway. The Davis Colliery Co. owns about 25,000 acres of coal lands and coal-mining rights in the well known Roaring Creek coal field in Randolph and Barbour Counties. It is the largest operator in that region and one of the leading mining companies of the state; its five plants are capable of producing daily 3500 tons of coal and 700 tons of coke.

In addition the Davis Colliery Co. is operating two mines in the Pittsburgh seam, on lands owned by the railway company—one at Bower and one at Copen; present output, about 800 tons and 600 tons, respectively.

There are 18 or 20 coal-mining companies on the line of the road operating some 24 mines.

Troubles of the Paint Creek Bondholders

The Paint Creek bondholders' meeting was made interesting by those opposed to permitting the trustee to exchange $1,250,000 Crescent Coal & Lumber 5s with 50% stock, now held in the sinking fund, for $1,250,000 of outstanding Paint Creek, 5s, which latter bonds apparently the Lackawanna Coal & Lumber Co. interests have finally purchased or will purchase in the open market, in order to effect the exchange and release the Crescent's so that they may be canceled and at the same time automatically release $1,250,000 Lackawanna Coal & Lumber 6s now held by the Republic Trust Co., trustee, against a like amount of Crescent's in the lumber company treasury. The entire issue of Crescent's would be canceled and the property be subject to the lien of the Lackawanna Coal & Lumber 6s outstanding, whereas the Paint Creek bonds which at the present have a pro rata interest in 40% of the Crescent's property, would lose this equity and have nothing as a compensation except that the issue would be reduced from $3,000,000 to $1,750,000 of outstanding bonds. The exchange was voted through by $1,088,000 of bonds, and opposed by $535,000 bonds, practically $900,000 being unrepresented.—"The Commercial and Financial Chronicle."

COAL SECURITIES

William J. Hoey reports the market on various coal securities for the week ending Feb. 7, as follows:

Stock	Bid	Asked	Stock	Bid	Asked
American Coal	80	100	Jef. & Cle'fd. C. & I. Pfd.	70	80
American Coal Products	83	84	Kentucky Block Cannel	40	60
Amer. Coal Prod. Pfd.	104	106	Lehigh Valley Coal Sales	185	195
Big Muddy Coal & Iron	75	100	Leh. & Wilkes-Bar. C. Co.	310	360
Burns Bros.	50	53	Mahoning Coal R. R.	700	750
Burns Bros. Pfd.	94	99	Mahoning Investment	64	70
By-Products Coke	112	120	Maryland Coal of Md.	3	6
Central Coal & Coke	80	86	Maryland Coal of W. Va.	7	9
Central Coal & Coke Pfd.	78	86	Maryland Coal of W. Va. (5% Bonds)	54	62
Chicago Lumber & Coal	45	55	Midland Coal	80	90
Chicago Wil. & Ver. Coal	25	32	N. Y. S. & W. C. Pfd.	15	30
Colo. Fuel & Iron Pfd.	150	160	Pocahontas Con. Collieries	92	101
Cumberland Corporation	10	14	Pocahontas Con. Coll. Pfd.	98	105
Cumberland Corp. Pfd.	39	44	Texas & Pacific Coal	97	101
Del. Lack. & West. Coal	260	270	Unite Coal of Pittsburgh	3	101
Elkhorn Fuel	4	10	Victoria Coal & Coke Pfd.	40	80
Elkhorn Fuel Pfd	55	70			
Hocking Valley Products	1	4			

No important dividends were announced during the week.

The New River Co.—Indications are that the British syndicate formed to take over the New River Co. and other West Virginia properties, means business. The alleged recent option of the New River properties provide for a payment of $600,000 Feb. 16, the balance to be payable not later than June 30.

Hocking Valley Products Co. (Earnings 1913)

Gross Earnings	Net Earnings	Interest, Taxes & C.	Sink. Fund. Reserve & C.
$628,965	$198,593	$176,737	$62,693

Leaving Deficit Balance of $40,897.

The earnings of the Maryland Coal Co., of Maryland, should show a big increase this year over last, as they will begin shortly to ship coal from the new mine recently opened on their property.

There is a larger demand lately for bonds of coal companies; some of the better class have made good advances in prices since Jan. 1.

It is quite possible that the Colorado Fuel & Iron Co. will soon pay more of the back dividends on the preferred stock. The bid side for stock has advanced over 20 points since the latter part of 1913.

Index of Current Coal Literature

We will furnish a copy of any article (if in print) for the price quoted. Where no price is quoted, the cost is unknown. Inasmuch as the papers must be ordered from the publishers, there will be some delay for foreign papers. Remittance must be sent with order.

ACCIDENTS AND THEIR PREVENTION

Mining Accidents in 1912. Coll. Guard., Dec. 24, 1913; 1⅔ pp. 40c.

Monthly Statement of Coal-Mine Fatalities in the United States, November, 1913, with Revised Figures for Preceding Months. Albert H. Fay. Bureau of Mines; 18 pp.

BLASTING, EXPLOSIVES

Electric Blasting in Shafts with Relay Action Exploders. C. W. Morse. Min. & Sci. Press, Jan. 31, 1914; ½ p. 20c.

Powder in Open-Cut Mining. Coal Age, Jan. 3, 1914; 1 p., illus. 10c.

Sprinkling Machine for Use During Shotfiring. (Translated from Glückauf) Coll. Guard., Jan. 16, 1914; ½ p., illus. 40c.

The Use and Abuse of Explosives in Coal Mining. J. J. Rutledge, with preface by J. A. Holmes. Bureau of Mines, Miners' Circular 7; 44¼ pp., illus.

Tests of Permissible Explosives. Clarence Hall and Spencer P. Howell. Bureau of Mines, Bull. 66; 307 pp., illus.

BORING AND TUNNELING

The Modern Rock Drill. (Extract from paper of W. L. Saunders presented before the Butte meeting of the A. I. M. E.) Can. Min. Jour., Jan. 1, 1914; 2½ pp. 20c.

The Younger Generation of Rock Drills. Chas. Hirschberg. Min. & Eng. Wld., Jan. 31, 1914; 2 pp., illus. 20c.

BRIQUETTES

Briquetting in North America. C. T. Malcolmson. Coal Age, Jan. 10, 1914; 1 p. 10c.

Production of Coke and Briquettes in 1912. (From Part III of the General Report on Mines and Quarries.) Coll. Guard., Jan. 16, 1914; ⅔ p. 40c.

COAL DUST

Austrian Coal Dust Experiments. Fourth Report. (Translated from Oest. Zeit. f. B. u. H.) Coll. Guard., Jan. 16, 1914; 2 pp., illus. 40c.

Dust-Collecting Plant at Brackley Colliery. Iron Coal Tr. Rev., Jan. 16, 1914; ½ p., illus. 40c.

The Transition from Inflammation to Explosion of Coal Dust. Coal Age, Jan. 31, 1914; 4 pp., illus. 10c.

COKE

Coke Making in China. Min. & Sci. Press, Dec. 27, 1913; 1 p., illus. 20c.

Correlation of the Gas Lighting and Coke Oven Industries. (Lecture by J. E. Christopher.) Gas Wld., Jan. 17, 1914; 5 pp., illus. 40c.

Increased Use of Prepared Coke. F. C. Atwell. Coal Dealer, January, 1914; ¾ p. 20c.

The Automatic Control of Byproduct Coke-Oven Plants—II. A. Thau. Gas Wld., Jan. 3, 1914; 1½ pp., illus. 40c.

Types of Coke-Oven Plants as Seen in Operation—VII. (Semet-Solvay Installation at Normanby Park Steelworks.) Gas Wld., Jan. 3, 1914; 6 pp., illus. 40c.

COMPRESSED AIR

Air Compressors and Compressed-Air Machinery. (Chapter V on large compressed-air engines and mining machinery.) Robt. L. Streeter. Min. Mag., January, 1914; 18¼ pp., illus. 35c.

Air Compressor Testing. W. C. Lancaster. Power, Jan. 4, 1914; 3¼ pp., illus. 15c.

Moisture in Compressed Air. A. Hofmann. Power, Jan. 13, 1914; 2 pp., illus. 15c.

Sullivan Angle-Compound Power-Driven Air Compressor. Coal Tr. Bull., Jan. 2, 1914; 4½ pp., illus. 25c.

The Testing of Air Compressors. H. Keay Pratt. Coll. Guard., Jan. 9 and 16, 1914; 3⅔ pp., illus. 80c.

DRAINAGE, PUMPING, ETC.

Deep Mine Pumping and Air Lifts. A. E. Chodzko. Min. & Sci. Press, Jan. 17, 1914; 4 pp., illus. 20c.

Mine Drainage by Compressed Air. A. D. Spears. Coal Age, Jan. 17, 1914; ¾ p., illus. 10c.

The Oneida No. 2 Anthracite Drainage Tunnel. M. C. Reed. Mine & Quarry, January, 1914; 3½ pp., illus.

ELECTRICITY

Choice of Electrical Machinery for Use in Mines, with Discussion. (Paper by J. P. C. Kivlen read at A. M. E. E., West of Scotland Branch.) Iron Coal Tr. Rev., Jan. 2, 1914; 2¼ pp. 40c.

Maintenance of Mining Electrical Plant. (Paper by C. C. Reid read before the East of Scotland Branch of the A. M. E. E., Nov. 14, 1913.) Iron Coal Tr. Rev., Dec. 26, 1913; ⅔ p. 40c.

EXPLOSIONS

Dawson, New Mexico, Mine Disaster. Coll. Engr., January, 1914; 2¾ pp., illus. 35c.

Notes on the Prevention of Dust and Gas Explosions in Coal Mines. Geo. S. Rice. Bureau of Mines, Tech. Paper 56; 17¼ pp.

Prevention of Gas or Dust Explosions. (Paper by J. R. Booth read at the fourth annual Safety Boosting dinner of U. S. Coal & Coke Co., Jan. 10, 1914.) Coal & Coke Op., Jan. 29, 1914; ½ p. 20c.

Rock Castle Mine Explosion. Coal Age, Jan. 24, 1914; 1½ pp., illus. 10c.

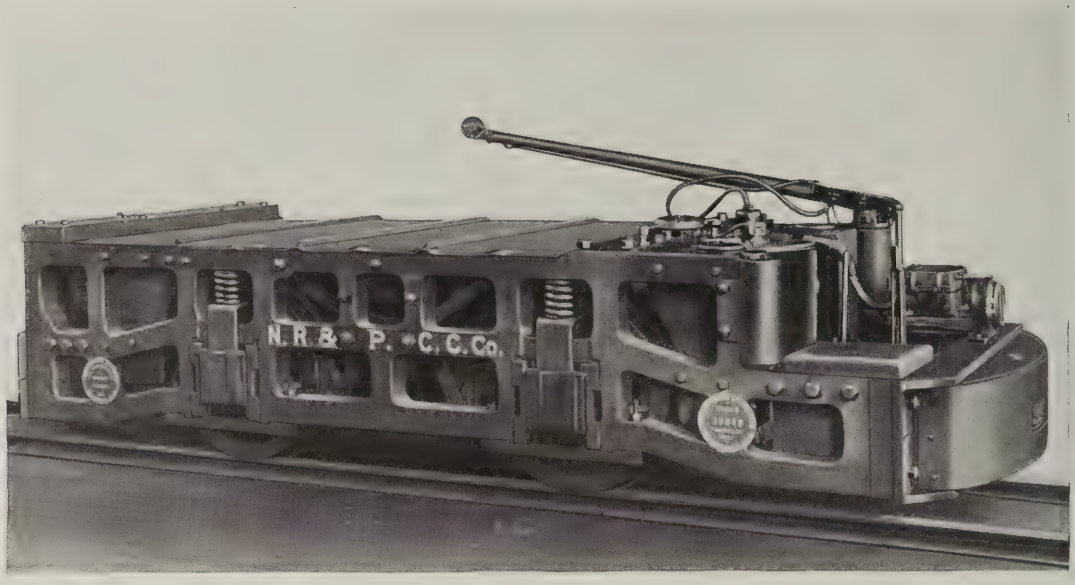
"Epping-Carpenter"

The Pump That Landed the Order

In the face of the competition of over 25 pump manufacturers and all kinds of price-cutting, "Epping-Carpenter" Pumps landed an important order for a $38,000 mine pumping installation. This is another instance where superiority of service rather than low price was the governing factor.

If "Epping-Carpenter" Pumps are superior for a $38,000 installation, isn't it possible they will please you on a single pump?



We have had 50 years' successful experience in building mine pumps including single and duplex mine pumps, triple expansion, Corliss high duty, centrifugal and power pumps for all heads and capacities.

Write for a Free Book on Mine Pumps

Anyone who is interested in the kind of pumps that makes the most sales when competition is greatest, should send for the Epping-Carpenter Salesman's Book. **Write today and you won't have to wait for the next edition of this interesting book.**

Barsteel Heavy Haulage Locomotive

4 Features of Baldwin-Westinghouse Barsteel Electric Mine Locomotives That Assure Maximum Tonnage with Least Expense

The Cast Steel Bar Frame which gives great strength with least weight; permits easy access to, and excellent ventilation for the motors.

The Vauclain Removable Gib which greatly facilitates the removal of journal boxes and permits inspection or replacement of all wearing parts with a small cost of time and labor.

The Oil and Waste Lubricating System for the motors, with specially designed bearings for long life in service, which has been adopted as a standard after years of investigation.

The Commutating-Pole Motors which insure sparkless commutation at all loads. As a result, the commutator and brushes are long lived and require little attention, brush renewals are seldom required, and carbon and copper dust inside the motor is practically eliminated.

These features are but few of many which have been incorporated in Baldwin-Westinghouse **Barsteel** mine locomotives in order to give the user the greatest possible service. You can obtain them only when you specify Baldwin-Westinghouse.

Address either company for full information.

VOLUME 5 MARCH 7, 1914 NUMBER 10

CONTENTS

WITH PRINCIPAL ARTICLES SUMMARIZED

*Illustrated Article

FOREWORD: *Page* 391

Some remarks concerning the practice of decorating the walls of an office with inspiring mottoes. One such message in the office of a Scotch friend emphasizes the responsibility of a man in the mines for his every act. A slight mistake, or a bit of carelessness, on the part of a single individual may affect the lives of a number of people for all eternity.

*SOME FRENCH AND GERMAN ELECTRIC HOISTS: *Pages* 392-394

Some recent installations for deep shafts are here described. The hoists are all fitted with direct-current motors, but the sources of supply are plain and flywheel motor-generator sets or low-pressure turbo units, operating on exhaust steam. COAL AGE, Vol. 5.

NOTIFICATION TO OPERATORS AND MINERS: *Page* 394

*SOME NEW TYPES OF ELECTRIC HOISTS: *Pages* 395-396

THE PHILADELPHIA CONFERENCE: *Page* 396

*TYPES OF ELECTRIC WINDING ENGINES: *Pages* 397-401

Local conditions governing the service of hoisting engines, which have a direct bearing upon the design, are here discussed. The systems of electric supply and control common in the coal fields are also described. L. F. Mitten. COAL AGE, Vol. 5.

RHENISH WESTPHALIAN COAL SYNDICATE: *Page* 401

THE PROPER USE OF OILS: *Pages* 401-402

*THE CARE OF WIRE ROPE: *Pages* 402-403

If a wire rope is carefully watched at work, it is possible to prevent much wear and tear. The article describes where the deterioration is to be expected, and the cure for it is obvious. COAL AGE, Vol. 5.

THE CONGRESSIONAL INVESTIGATION IN COLORADO: *Pages* 404-405

The operators admit the importation of arms, but declare that it was done to protect their property. They show clearly that the men were making good wages and had saved over a half million dollars. The right of the committee to subpoena witnesses, who are held by the governor, is denied. COAL AGE, Vol. 5.

*AN AIR-POWER CHART: *Pages* 405-406

A chart is here presented by means of which, if the volume of air handled and water gage are known, we can determine (1) the actual horsepower in the air, (2) the horsepower necessary for the engine or motor driving the fan, and (3) the diameter of the cylinder. In the latter case, we are to assume the piston speed. Dwight Gerber. COAL AGE, Vol. 5.

*METHOD OF OBTAINING TIME AND AZIMUTH: *Page* 407

*THE GASOLINE INDUSTRIAL LOCOMOTIVE: *Pages* 408-410

A general summary of the industrial railway field, with particular attention to the mine tramway. A short description is then given of the Vulcan gasoline locomotive, which has successfully met the exacting conditions of underground service. S. T. Nicholson. COAL AGE, Vol. 5.

REASONS FOR OPPOSING THE ANTHRACITE TAX: *Pages* 410-411

*THE EXPLOSION AT RAVENWOOD: *Pages* 411-412

This accident seems to prove the efficacy of shale dust as a preventive of widespread coal-dust explosions. It is stated that shale dust is not likely to cause lung troubles. Much depends on having dust-tight cars. Samuel Dean. COAL AGE, Vol. 5.

THE DUBOIS, PENN. CONVENTION: *Pages* 413-414

Patrick Gilday advocates fines for violation of agreements. The miners are anxious to start coöperative stores. COAL AGE, Vol. 5.

EDITORIALS: *Pages* 415-416

Electric Winding Engines—Reversing Mine-Air Currunts in Coal Mines—Mine Visitation—List of Fatal Coal-Mine Explosions—The Business Outlook—Prohibition in West Virginia.
